The statement also affirms the advisability of using milk as an excellent source of protein in child feeding programs.

Dairy Council is sponsoring further research on lactose intolerance. This is just another of the many areas of interest of Dairy Council, in the pursuit of better health for everyone through sound nutrition practices.

Dairy Council of the Twin Cities, St. Paul, Minnesota
A primary resource for nutrition education.
Affiliated Unit of National Dairy Council

About this time 50 years ago A. E. Benjamin presided at a meeting of the Hennepin County Medical Society in the medical library of the Donaldson Building, and Dean E. P. Lyon addressed the group on the subject: The medical school and public welfare. He said: "Last year we had 200 applicants, but only 103 of these were wholly free of scholarship deficiencies. Of the 103 we accepted, 86 . . . The medical school looks forward to such an increase in its facilities as will permit the enrollment of all students who desire to secure their medical education at the University of Minnesota."

Dean Lyons' address was printed in Volume 42 of *The Journal-Lancet*. From that reference and from Volume 5 of MINNESOTA MEDICINE are culled the following:

"It was said in a recent issue of the *Daily Press* of Minneapolis that the doctor's whiskey-pad saves 98,782 victims of colds in the year."

"Dr. W. J. Mayo delivered the John B. Murphy address before the American College of Surgeons in Philadelphia at which meeting honorary fellowship was conferred upon him and Dr. C. H. Mayo."

"Dr. Thomas J. Kinsella (Minnesota 1919), and Dr. Edward A. Regnier (Minnesota 1921) have become members of the Nicollet Clinic, Minneapolis, in the division of surgery."

"Physicians in Duluth are constantly asked if it is not advisable for patients with chronic throat and lung afflictions to seek a milder and presumably better climate than Duluth. There is quite a general impression among those not well informed on the subject that there are undesirable features about the climate of Duluth . . . As a matter of fact the climate of Duluth and vicinity is in many respects very similar to that of the Adirondack Mountains in the State of New York, known the country over as a popular resort, summer and winter, for patients suffering from pulmonary and throat diseases." [Note the careful avoidance of the word tuberculosis.]

Advertisement: "The Curtis Northwest Airplant Company has opened an office at the Curtis Hotel in Minneapolis and offers emergency service to members of the profession."

Advertisement: "Lewisville, Watonwan County, a town on the Omaha road midway between Madelia and Fairmont with a population of 229 (1920 census) is in need of a resident physician. Communications should be addressed to the mayor."

"During the last few years such important physical and technical advances have been made with the aid of *x-rays* that it might not be far from correct to class the discovery of Professor Roentgen as one of the most important of the last quarter of a century."

Book Review: The Place of Version in Obstetrics. Irving W. Potter. Mosby $5.00. . . . "Let no one lose sight of the fact that Dr. Potter is a mighty clever obstetrician and that on the whole he is getting comparatively good results with his methods of delivery. His first paper, which was never published, deals with 500 versions . . . he had 57 still births, 11.4%. In his last report he had 1130 deliveries in a year of which 938 were by version and 100 by Caesarean section . . . A man who delivers 1130 women in one year must shorten the hours of labor."

"A letter from Vienna (by E. I. Tuohy): . . . Is Vienna the medical center it was before the war? Is it a good place for Americans to go now? The old morgue in the Krankenhaus is cleaner and sprightlier than it has ever been before, thanks to the Rockefeller Foundation. Erdheim is sectioning and demonstrating on the same old stone table used by Rokitansky. The gross pathology opens up like the pages of a beautifully bound book . . . While many courses are offered in English . . . it is far better to blunder badly into the German language. It is a virile speech and has already withstood most heroic punishment at the hands of some of us . . ."

"Conditions simulating an acute leukemia . . . In 1915 Hall reported to the Royal Society of Medicine a case resembling acute lymphatic leukemia with recovery in a young adult. In 1920 Sprunt and Evans described six similar cases. Sprunt and Evans cases were all young adults between the ages of 23 and 29. The striking clinical features are these:

"1. An acute febrile disease, usually with a local infectious, but non-suppurative process.

"2. Enlargement of the lymph glands of the neck, axillae, or groins, or combination of these, and enlargement of the spleen.

"3. A relative increase in the mononuclear white cells, either with or without a moderate leucocytosis, less than 20,000 usually.

"4. The occurrence of certain white cells difficult to classify, but which are generally assigned as

lymphoblasts.

"5. Recovery."

All of these Fifty Year Club members have given a lifetime of service to the State of Minnesota and have earned the gratitude of its citizens. The undisputed leader of this class, of course, is Owen Wangensteen, the maker of professors of surgery, the outstanding surgical educator of our time. The professor's professor. The medical class of '22 will not be forgotten.

Reuben Berman, M.D.
Editor

Sigmoidal Complications of Left Ovarian Enlargement

With their practical and usual pragmatic approach to surgical problems, Drs. Lee and Associates* suggest a practical point, i.e., to remove the left ovary instead of the right if there is a choice when doing pelvic surgery. Diverticulosis and or diverticulitis of the sigmoid colon should always be considered in the differential diagnosis of left adnexal masses, especially from the fifth decade of life on. General and gynecological surgeons are well advised to consider neoplasms and inflammatory processes and endometriosis with left lower quadrant abdominal and left adnexal masses, and to be prepared for injury to and involvement of the sigmoid colon and the appropriate surgical therapy for such.

Mancel T. Mitchell, M.D.
Minneapolis, Minnesota

Surgical Treatment of Vascular Ring

Vascular ring has long been recognized as a serious congenital malformation that may cause repeated pulmonary infections and death in early infancy. Less commonly, patients with a vascular ring will remain asymptomatic until adult life. Drs. Thompson and Read[12] reported a case of an adult with right aortic arch and anomalous left subclavian artery which produced a ring effect in combination with left ligamentum arteriosum. As the authors indicated, their repair was similar to that proposed for patients with the reverse situation, that is, a left arch and an anomalous right subclavian artery. Arterial continuity was restored by anastomosis of the proximal end of the subclavian artery to the ipsilateral carotid artery.

The anomaly of right aortic arch, aberrant left subclavian artery, and left ligamentum constitutes a relatively rare form of vascular ring. We have encountered only one such case, that of a 10-month-old boy, in a series of 19 patients with vascular ring who underwent corrective surgery.[1] In addition to late onset of symptoms, the authors' patient was somewhat unusual in that his presenting symptom was dysphagia. Most patients with vascular ring who are symptomatic in infancy and childhood have predominating symptoms related to respiratory distress and repeated pulmonary infections. It is clear, however, that some patients may become symptomatic only in adult life and that the first symptom may be dysphagia. In some instances, this may result from aneurysmal dilation of the aberrant vessel.[2,3]

In principle, reconstitution of subclavian artery blood flow is desirable in order to prevent intermittent claudication of the involved arm or neurologic symptoms from the development of a subclavian steal syndrome.[4,5] No cases of severe distal ischemia have been reported from division and suture of an aberrant subclavian artery at its origin from the aorta, although rare cases of gangrene of the arm have been reported after the use of a normally situated subclavian artery for other purposes.[6,7] Similarly, a significant subclavian steal phenomenon has not been reported after division of an aberrant subclavian artery, but it is reasonable that such could occur, as symptomatic subclavian steal has developed after Blalock-Taussig anastomoses.[8]

The authors pointed out that only a few aberrant right subclavian arteries are symptomatic. It is interesting that none of the cases in our series[1] involved an aberrant right subclavian artery with a descending left thoracic aorta, in contrast to many series in the literature. There are many uncertainties about the symptoms this anomaly may cause. It does not form a true ring, with the exception of the rare form in which right ligamentum arteriosum or right patent ductus arteriosus develops. Of 106 patients at the Mayo Clinic,[9] only five had dysphagia, but in none of these five was dysphagia attributed to the aberrant right subclavian artery. There must be other anomalies to cause such symptoms, as suggested by Klinkhamer.[10] A vascular ring effect is common, however, when there is an aberrant left subclavian artery and a right descending thoracic aorta (authors' case), since the left ligamentum arteriosum connecting to the left pulmonary artery completes a ring.

The authors disconnected the subclavian artery from the aorta through a left thoracotomy and then anastomosed the distal end of the artery to the left common carotid artery. From the technical standpoint, this procedure may be simpler than reattaching the subclavian artery to the ascending aorta in its usual location. A similar technique is commonly employed for revascularization of a subclavian or innominate artery with proximal occlusion, in which a graft is sewed end-to-side to the ipsilateral common carotid artery and end-to-side to the involved vessel distal to the obstruction. Temporary complete or partial occlusion of the carotid artery, however, carries a small but distinct hazard from cerebral complications caused by the interruption of normal cerebral blood flow. This hazard is not present when a side clamp is employed on the ascending aorta for anastomosis.

The authors have demonstrated again that it is not essential, as has often been recommended in the past, to approach an aberrant subclavian artery through the pleural space in which the descending thoracic aorta is situated. This is similar to our experiences of satisfactory exposure of the junction of an aberrant subclavian artery

with the aorta through either pleural space, when it has been necessary to enter one particular side for other considerations. For example, an aberrant right subclavian artery arising from a left descending thoracic aorta was satisfactorily exposed through a right thoracotomy when it was necessary to perform lobectomy simultaneously because of a solitary pulmonary nodule in the right middle lobe.

If reanastomosis of the subclavian artery is being considered, however, it is preferable to enter the pleural space on the same side as the artery. Performance of the entire operation through a single incision would seem to be preferable to the two-incision operation described by Siderys.[11] Therefore we would consider the authors' contention sound: that the patient with an aberrant right subclavian artery and left arch should be approached through a right thoracotomy and the divided subclavian artery anastomosed to the right common carotid artery (or ascending aorta) and that patients with a reverse situation should have a similar procedure conducted from the left side.

Decision Making in Scoliosis

THE MOST COMMON pitfall in the treatment of scoliosis is the failure to recognize the insidious progression of a spinal curvature in a growing adolescent while she is being "observed" by her physician.

The article by Winter and Moe* (also pioneers in the treatment of scoliosis, although they modestly neglected to include themselves in this category in their article) stress several important points worth re-emphasizing.

1. Even though a curvature is mild in a growing patient, evidence of progression of the curve is indication for treatment with the Milwaukee brace.

2. Once growth has ceased in the older adolescent, the Milwaukee brace is ineffective in obtaining lasting correction.

3. Observation of the patient's curve, without treatment, is indicated only in those patients in whom a curvature is mild and does not progress. Lack of progression must be established by x-rays made in the erect posture at regular intervals through the period of spinal growth.

4. There is no place for exercise as the sole form of therapy for scoliosis. Exercises improve posture but do not reduce curves or prevent progression.

5. Spinal fusion is indicated for those curves which are too severe to be controlled by the Milwaukee brace.

Letters to the Editor

Dear Editor:

WAS I GLAD to see SNOMed (deriv of SNOP) commended by AHW MD in MINN MED of JUN. WHAT a SCOOP. I am sure SNOP was gratified at its CAP raising reception by AFIP in DC and by ACS INC in NY. But what a shame for the CIOMS; a good thing it seems that a generous UNESCO came through with the $ so that they could sire IND after all. However, although Topography (T) was clear and Eitology (E) easily explicable, Function (F) seemed + −, even when called X Y. May I suggest that before more Committees for Rephrasing, Elucidation and Testing of International Nomenclatures (CRETINS) are produced an IUD is placed in UNO WHO, ie AMA CMITS (Amy Schmidt (Ger) (Adapt)).

I remain in IBM-convenient form,
SOC SEC NO 206 42 4151

Rochester, Minnesota

Dear Editor:

It was with great pleasure that each of us had the opportunity to see, all at one time and in one place, the dedication to Dr. Rice. Since each of us has known him and worked with him and has had the opportunity to consider him a friend as well as a physician to whom we would like to refer patients, we feel that MINNESOTA MEDICINE has helped us crystalize many of the things we did not know about this very modest citizen in our midst.

Request for Physican's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers have received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Because of limitation of space, pictures oriented horizontally are preferred. All pictures will be returned if identified with the name and address of the physician. Please submit your pictures as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

Farrell Stiegler, M.D.
Cover Editor

In Appreciation

The many fine technical exhibitors who participated in the exhibit during the recent Minnesota State Medical Association Annual Meeting are deserving of our recognition and a hearty "thank you!" Not only did the presence of these exhibits enhance the educational quality of our meeting, the support provided by our exhibitors is essential to the continuance of our traditionally outstanding scientific program.

The firms listed below participated in our 1972 Annual Meeting exhibit and we voice a collective expression of our sincere appreciation. May we also suggest that you retain this listing and express your personal appreciation when their representatives call upon you.

"The history of science, and in particular the history of medicine...is... the history of man's reactions to the truth, the history of the gradual revelation of truth, the history of the gradual liberation of our minds from darkness and prejudice."

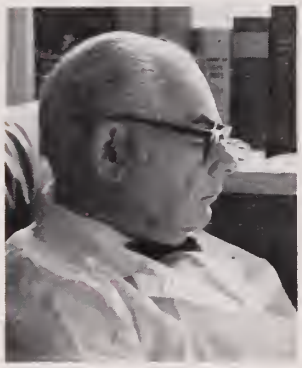
–George Sarton, from "The History of Medicine Versus the History of Art"

Would it be useful in clinical practice to have government predetermine drugs of choice?

Opinion

Results of a survey of physicians:

13.3%
Yes, it would be useful.



86.7%
No, it would not be useful.

Dialogue

Would it be useful in clinical practic to have government predetermine drugs of choice?

Doctor of Medicine

Walter Modell, M.D.,
Professor of Pharmacology,
Cornell University
Medical College,
Editor,
Clinical Pharmacology
& Therapeutics,
Drugs of Choice,
Rational Drug Therapy

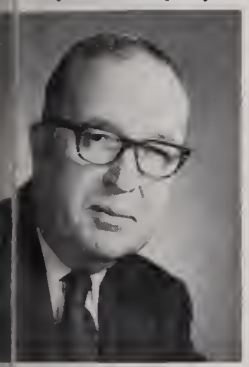
The proposition that government should determine one or two "drugs of choice" within a given therapeutic class reflects the belief that a similarity in molecular structure insures a close similarity in pharmacologic effect. But this is by no means the rule. An obvious example would be in the field of diuretics, where a small change in chemical structure accounts for substantial differences in concomitant effects such as potassium excretion.

Any attempt to dictate the "drug of choice" would be complicated by the fact that some populations demonstrate a bimodal distribution in their reaction to drugs. If the data on drug response are mixed for the total population, one drug will appear to be as useful as the other. But if drug response is reported separately for different segments of the population, drug A will be found to be better for one group and drug B for the other.

It may, of course, be possible to determine drugs of choice in particular categories on a broad statistical basis. But there are always certain patients in whom a drug produces odd, unpredictable or idiosyncratic reactions. So, though a drug might statistically be the most useful one in a given situation, individual variations in response might make it the *incorrect* one.

The point I wish to make is that if two, three, four or more drugs in one class are of approximately equal merit, that in itself is justification for their availability. Exceptional cases do arise in which one drug would be useful to a certain segment of the population and another drug would be of no use at all. In the practice of medicine, the physician must be prepared to treat the routine as well as the unusual case.

Another objection to the determination of a drug of choice is that precise statements of *relative* efficacy are very difficult to make—much more difficult than statements of efficacy. For example, in testing drug efficacy, it is easy to determine the difference between a drug that is effective in treating a condition and one that is not at all effective. Thus, it is fairly easy to determine whether a drug is more effective than a placebo. But if you compare one drug that is effective with another drug that is also effective, and the relative differences between them are very slight, statements of relative efficacy may be very difficult to make with assurance.



I do not mean to imply that relative efficacy statements are not useful or can never be made. With some groups of drugs (e.g., analgesics), extensive study and precise methodology have yielded useful information on relative efficacy. But in most situations, such information can be acquired only through studies encompassing three to five years of use in many more patients than are used to compare drugs with a placebo for the introduction of a drug into commerce. It is really only after practitioners use a drug extensively that relative safety and efficacy in practice can really determined.

The Bureau of Drugs suggested the package sert as a possible mean communicating informa on relative efficacy of d to the physician. I find objectionable, since I not believe the physi should have to rely on source for final scien truth. There is also a p tical objection: Since physicians actually pense drugs, they sel see the package insert any event, I would m tain that the physi should know what dru wants and why without pending on the govern or the manufacturer to him.

Undoubtedly, physic are swamped by exces numbers of drugs in s e therapeutic categories. I am well aware that m drugs within such c gories could be elimin without any loss, or haps even some profit the practice of medic e But, in my opinion, nei r the FDA nor any o er single group has the ex tise and the wisdom ne sary to determine the "drug of choice" in l areas of medical practi

Maker of Medicine

eth G. Kohlstaedt, M.D.,
Vice President,
Medical Research,
Eli Lilly and Company

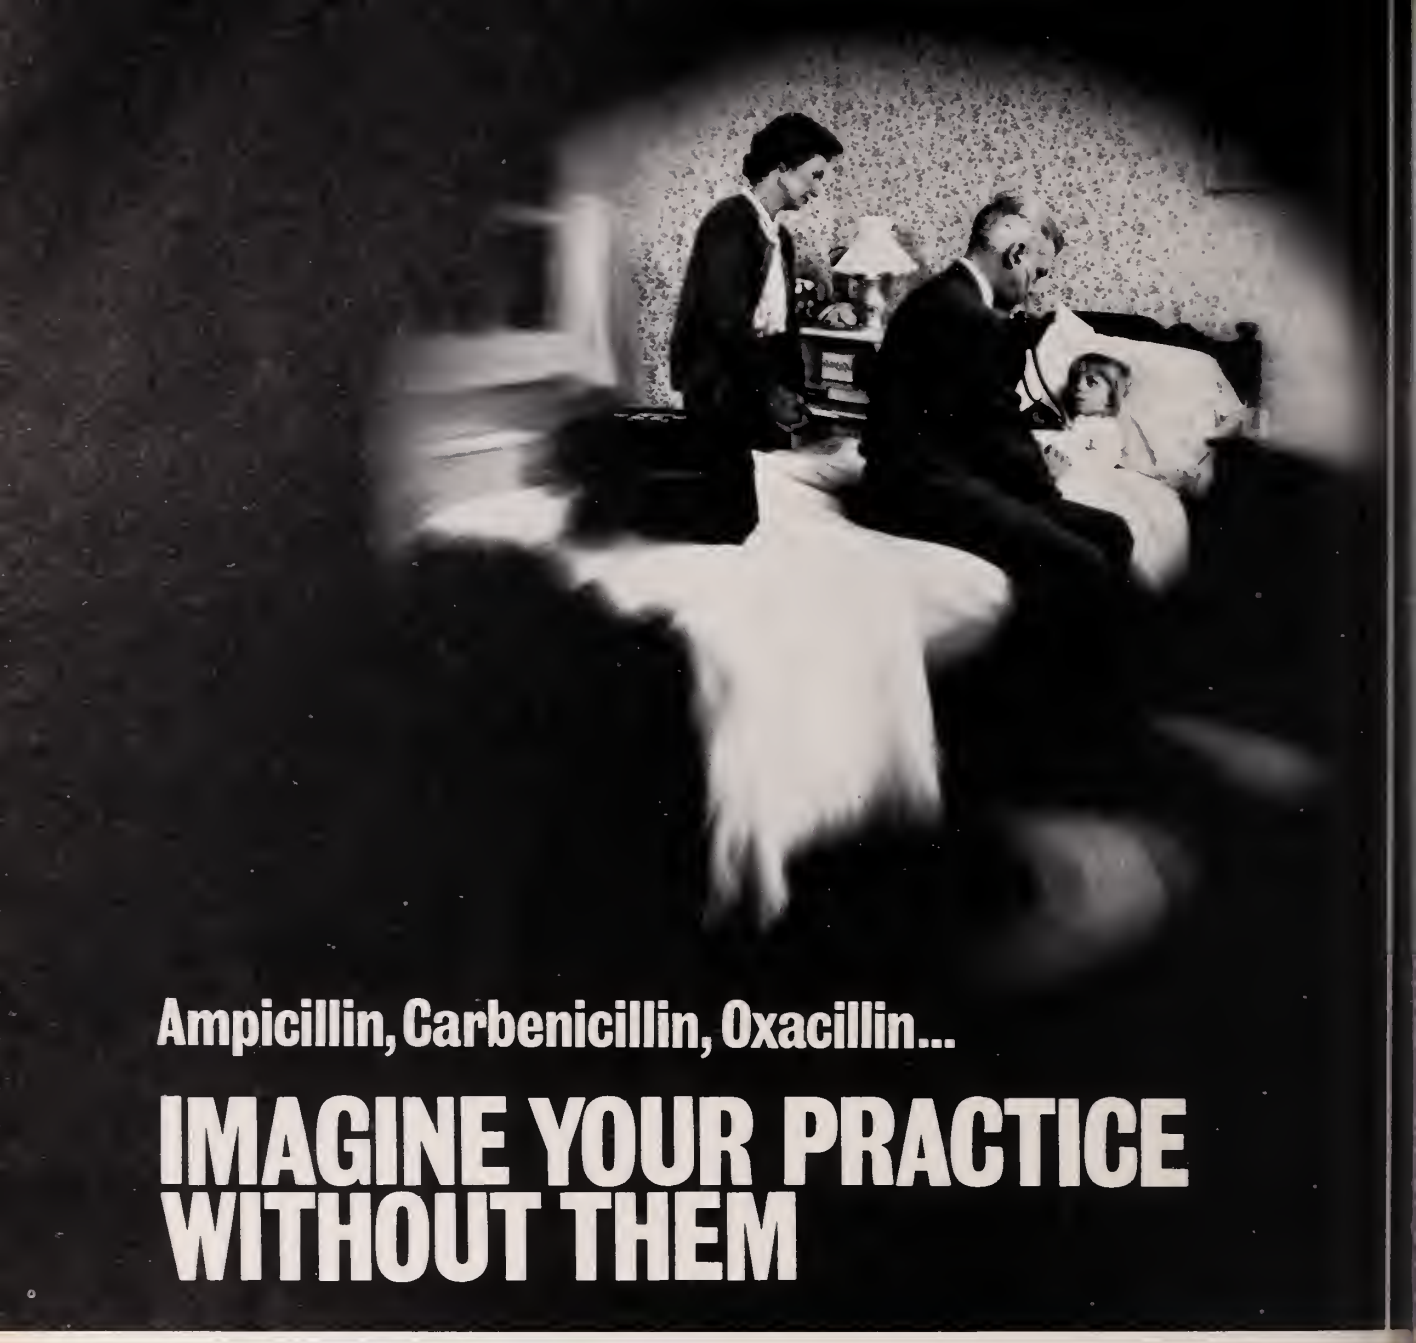
In my opinion, it is not
e nction of any govern-
e or private regulatory
e y to designate a "drug
oice." This determina-
o hould be made by the
y cian after he has re-
i l full information on
e roperties of a drug,
c hen it will be based on
s xperience with this
u and his knowledge of
e ndividual patient who
s king treatment.
I an evaluation of com-
n ive efficacy were to be
a , particularly by gov-
r ent, at the time a new
t is being approved for
a eting, it would be a
c t disservice to medi-
n nd thus to the patient
c consumer. For exam-
e when a new therapeu-
t gent is introduced, on
e asis of limited knowl-
it may be considered
e more potent, more
t tive, or safer than
t ucts already on the
e ket. Conceivably, at
time the new drug
u l be labeled "the drug
h oice." But as addi-
o l clinical experience is
c nulated, new evidence
a become available.
a r, it may be apparent that the established products should not be so easily dismissed.

Variation in patient response to drugs constitutes one of the major obstacles to the determination of "drugs of choice." We are just beginning to open the door on pharmacogenetics, but it is evident that genetic differences cause wide variations in the way drugs are absorbed, metabolized, etc. This fact alone is sufficient to make unrealistic the idea that there is one drug in each class to be used for every human being.

The problem of determining relative drug efficacy is an extremely complicated one. Comparison with other drugs of the same class should not be a prerequisite for marketing a new substance. In some therapeutic areas, it may be difficult to make accurate comparisons. For example, in the treatment of infections it is not possible to conduct crossover studies. Recovery may be influenced by factors which cannot be controlled or measured, i.e., natural host resistance and virulence of infective agents. A drug's acceptability must often be judged on the basis of its own performance, and this may be limited to experience in a relatively small patient population. If the introduction of a new drug must await the adequate establishment of relative efficacy, the duration of clinical trial and extent of studies would be greatly prolonged, particularly for rare or unusual conditions. The availability of a new drug would be delayed. Many patients might suffer needlessly and lives might be lost.

Relative efficacy can best be established by experience in a general patient population through regular channels of clinical practice. The physician considers the patient as a whole, which means the patient often has multiple problems and drugs must be selected with this in mind. Hence, a "drug of choice" in an uncomplicated case may not be the best drug for a patient with associated problems. Publication of well-controlled studies in medical journals may provide comparative evidence; discussions at medical meetings, presentations at postgraduate courses, and the new audiovisual technology may bring evidence to physicians on comparative therapy. In a free medical marketplace, a drug that does not measure up will fall into disuse. For example, broad clinical experience has established vitamin B_{12} as the "drug of choice" for the treatment of primary pernicious anemia. No amount of advertising or promotional effort by the manufacturer could increase the use of liver extract for this anemia. However, a physician may wish to employ parenteral liver preparations for a special purpose.

In the field of surgery, peer review in the hospital has brought significant improvement in the use of new techniques and procedures. Something of this nature would be useful in the area of drug therapy. However, it should be developed by the medical profession itself and would necessitate, for its proper function, an improvement in the dissemination of reliable data on clinical pharmacology of drugs under consideration.



Ideally, information on the relative efficacy of drugs should be gathered and assessed by the physicians who actually administer the specific agents to a specific patient population. To do this, they will need even more information on the drugs they use — information that the pharmaceutical manufacturers must begin to provide if government regulation of *"drugs of choice"* is to be avoided.

Ampicillin, Carbenicillin, Oxacillin...

IMAGINE YOUR PRACTICE WITHOUT THEM

In 1957 Beecham scientists discovered and isolated 6-APA, the penicillin nucleus that opened the way to a new generation of semi-synthetic penicillins. Over the past 14 years more than 3000 different semi-synthetic penicillins have been synthesized and evaluated by our staff. The fruits of their work are in your hands today. Others will be in your hands tomorrow.

Need we say more?

☐ Pyopen (disodium carbenicillin) vials for injection equivalent to 1 gm. and 5 gm. of carbenicillin.
☐ Bactocill (sodium oxacillin) capsules equivalent to 250 mg. and 500 mg. oxacillin and vials for injection equivalent to 500 mg. and 1 gm. oxacillin.

Fifty Years of Faithful Service

Alvin G. Athens, M.D.

Dr. Alvin G. Athens specialized in ophthalmology and otolaryngology. Born in Fairmount, Indiana, 1887, he attended school in Summitville, Indiana; receiving his A.B. degree from De Pauw University, 1915 and obtained his medical education at Johns Hopkins University, graduating in 1919. He took postgraduate work at Pennsylvania Post Graduate School, at the New York Eye and Ear Hospital in New York City, and at the Chicago Polyclinic. Dr. Athens served in Buhl, Minnesota, for two years, for 36 years in Duluth, and retired in 1960.

J. Richards Aurelius, M.D.

Dr. J. Richards Aurelius has one phase of his medical experience which for a long time has been of great interest and satisfaction to him. This is his association with the detection of tuberculosis and the role of medical and public health organizations in the exciting period of this disease from about 1925 to the present.

During this period Dr. Aurelius saw a wide range of therapy from simple bed rest, then pneumothorax, thoracic surgery to a large group of antibiotics to a period now of a remarkably specific control, possibly in the range of eraxication.

A roentgenologist, certified by the American Board of Radiology, Dr. Aurelius received his M.D. degree from the University of Minnesota and served as a Fellow in radiology at the Mayo Foundation. In 1928, he became an assistant instructor in the Department of Radiology, University of Minnesota, and later served as clinical professor retiring in 1966.

Alfred N. Bessesen, Jr., M.D.

Alfred N. Bessesen, Jr., born in Minneapolis September 27, 1896, followed the medical tradition of his parents, A. N. Bessesen, M.D., and Florence Holland Bessesen, M.D. He received all his degrees—B.S., B.M., and M.D., the latter with distinction, from the University of Minnesota, where he was elected to Sigma Xi and received the Geist prize for research in anatomy. He served his internship at City-County Hospital, St. Paul, and the University of Minnesota Hospitals.

Dr. Bessesen's primary hospital affiliation throughout his career has been with Methodist Hospital, Minneapolis, where he was president of the medical staff in 1950. He served in World Wars I and II as commander medical corps, U. S. Naval Reserve, with duty in the Philippines.

Dr. Bessesen pioneered in the medical care of alcoholics in the early 1940's and introduced the use of Disulfiram (Antabuse) in October, 1951, when it was first available in the U.S.

He has been a lifelong supporter of varsity athletics at the University of Minnesota, particularly through the Williams Scholarship Fund.

Dr. and Mrs. Bessesen have two children, Mrs. William G. Heegaard, Alexandria, Minnesota, and Alfred N. Bessesen, III, Columbus, Ohio, and seven grandchildren.

Ferdinand W. Bofenkamp, M.D.

Dr. Ferdinand W. Bofenkamp is a general practitioner with 48 years of service in Luverne and Rock County. Born in Ellsworth, he attended Dubuque University, Dubuque, Iowa. Doctor Bofenkamp received his M.S. degree from St. Louis University Medical School, St. Louis, Missouri, and served his internship and residency at St. John's Hospital, St. Louis, Missouri.

Lewis R. Bouma, M.D.

Dr. Lewis R. Bouma, surgeon, was born in Chicago. He is a graduate of the Universities of Iowa, Iowa City, and Minnesota. Doctor Bouma interned at Mounds Park Hospital, St. Paul, and did postgraduate work at New York College, New York. He served on the surgical staff of Bethesda Hospital, St. Paul.

Ruth E. Boynton, M.D.

Dr. Ruth E. Boynton was born and grew up in La Crosse, Wisconsin. After three years of premedical education at La Crosse State University, she attended the University of Wisconsin, for the first two years of medical school, receiving the B.S. degree in 1918. In 1921 received the M.D. degree from the University of Minnesota Medical School.

Her entire professional life was spent in the field of College Health and Public Health. After a few years on the staff of the Students Health Service, during which time graduate work was taken leading to an M.S. degree in Public Health, she became Director of the Division of Child Hygiene of the Minnesota Department of Health, a position held for four years.

In 1927 Dr. Boynton returned to student health work for one year at the University of Chicago, and from 1928 to retirement in 1961, she was at the University of Minnesota. From 1936-1961 was Director of the University Health Service and Professor of Public Health at the University of Minnesota.

From 1939 until 1961 she was a member of the State Board of Health, serving as President for two years.

Dr. Boynton was recipient of a Fulbright Research Award for six months study of Student Health Services in Britain in 1951.

In addition she was recipient of the following awards: Edward Hitchcock Award of the American College Health Association; Harrington Award given by the Minneapolis Junior Chamber of Commerce for service in public health and Albert J. Chesley Award of the Minnesota Public Health Association.

Herbert Boysen, M.D.

Dr. Herbert Boysen was born at Alvord, Iowa, March 4, 1898. He moved to Sioux City, Iowa in 1910 and graduated from high school in 1916. He attended the State University of Iowa where he took his premedic work and graduated from the College of Medicine in 1922. His internship was at the Receiving Hospital in Detroit, Michigan, 1922-23. In October, 1923 he was married to Minnie L. Olson and they have one son, Dr. James F. Boysen, a pediatrician at Sioux City.

Dr. Boysen has practiced at Truman, Minnesota 1923-26, at Welcome, Minnesota 1926-41 and at Madelia, Minnesota since that time. He has been secretary of the Blue Earth Valley Medical Society for the past 27 years.

Leo C. Culligan, M.D.

Dr. Leo Culligan's premedic work was taken at St. Thomas College and at the University of Minnesota, graduating in Medicine in 1922 and interning at Ancker Hospital in St. Paul, July 1922 to July 1923. He was accepted as a fellow in surgery at the Mayo Foundation July, 1923 and returned to St. Paul in 1926 where he practiced in surgery with his brother John until 1930.

The depression days of 1930 were spent at the Veteran's Hospital, Department of Surgery until 1943. In 1943 he took over the offices of Dr. Arthur Strachauer in association with Dr. Frank Hirshfield, Doctor Strachauer having retired about that time. Since that time he has been in practice in surgery doing the major portion of his work at St. Mary's Hospital.

In 1951 Dr. Culligan was Chief of Staff at St. Mary's Hospital, and in 1952 was elected president of the Minneapolis Surgical Society.

In 1927 he was married to Leone Dennis, from Marquette, Michigan, a former nurse from St. Mary's Hospital at Rochester. Eight children and 51 grandchildren are the result of this union.

He is still actively engaged in the practice of surgery in Minneapolis.

Raymond J. Dittrich, M.D.

Dr. Raymond J. Dittrich, as an orthopedic surgeon, has done extensive studies on lumbo dorsal fascia. Doctor Dittrich did postgraduate work at the University of Iowa, Iowa City; Los Angeles Orthopedic Hospital; and Gillette State Hospital, St. Paul, after receiving his M.D. degree from the University of Minnesota. He is certified by the American Board of Orthopedic Surgery and is a Fellow in the American Academy of Orthopedic Surgeons.

Benjamin Anton Dvorak, M.D.

Dr. Benjamin Anton Dvorak devotes his services to the field of surgery and general medicine. He obtained his B.S., M.B., and M.D. degrees from the University of Minnesota where he also took his postgraduate work in surgery and gynecology. He was on the surgical staff at Iowa State University Hospital, Ames, Iowa, in 1923 and 1924. Later he came to Minnesota as an instructor at the University Medical School and joined the staffs of St. Mary's and Deaconess Hospitals in Minneapolis.

In addition to his career in medicine, Dr. Dvorak had a career in athletics. While at Iowa State University he coached the football team 1923-24 and played football at the University of Minnesota in 1917, and 1920; pro football for the early NFL the first year of its organization, 1921. He captained and quarterbacked a championship football team while with the Eastern Army Ambulance Corps in 1918. In 1919 for several months, he played professional baseball with Louisville in the American Association, until returning to Medical School. For some years, he played trombone with the University of Minnesota Symphony Orchestra and the Minneapolis Symphony Orchestra, and was solo trombonist with the University of Minnesota Concert Band, 1915 to 17. Dr. Dvorak was born at New Prague, Minnesota, in 1896.

Edward T. Evans, M.D.

The Evans family made a large contribution to medicine; Dr. Evans' father was a Physician and Surgeon; one brother entered the field of internal medicine; another brother, the field of neurosurgery. Dr. Evans was born at LaCrosse, Wisconsin, in 1900. He received his education at Notre Dame University, the University of Wisconsin, and graduated from Harvard Medical School in 1922. Postgraduate training at the Boston Floating Hospital and Boston City Hospital in pediatrics, obstetrics, gynecology and general surgery. He did his Orthopaedic postgraduate work at the Hospital for Ruptured and Crippled in New York City, the Continental Clinics and under Sir Robert Jones in Liverpool and London. Dr. Evans was since 1927 a member of the teaching staff of the University of Minnesota in the Department of Surgery in Orthopaedics and now is an Emeritus Professor (Clinical) of Orthopaedic Surgery. He was Chief of Resident training in Orthopaedics at the Veteran's Hospital at Fort Snelling, as well as serving as a consultant there.

He was an infantry lieutenant in World Wars I and II, served over four years as Chief of Orthopaedic Surgery of the 26th General Hospital (U. of M.) in England, North Africa and Italy and at Billings General Hospital at Fort Benjamin Harrison, Indiana with the rank of Lt. Colonel. He was awarded the Legion of Merit in 1946. In 1957 he was consultant for the Surgeon General to the Far East Command.

He was president of the Clinical Orthopaedic Society, and the Association of Bone and Joint Surgeons and twice president of the Min- Da- Man Orthopaedic Society.

Aaron Friedell, M.D.

His mother's oft repeated suggestions in childhood was: (1) "Make knowledge accumulation your principle aim in life. With knowledge and experience you develop wisdom (most important)." (2) "Silver and gold can blindfold the eyes of wise men."

The above ideas were put to a hard test when as a high school junior Dr. Friedell after school worked for the Universal Film Company. One day he was given a film package, a first run for Red Wing Theater, to be delivered to the train (five blocks away). Although he ran all the way he missed the train.

In his pocket he had $2.10 and there upon took a taxi for the St. Paul Railroad Station and his mission was successful. With ten cents left he returned by streetcar to find the office group all upset (two and one half hours for my return—at 6:00 p.m.).

The manager called Dr. Friedell the following day and offered him a job to be trained as an assistant booker at a starting salary of $25.00 a week. The offer was not accepted as it would interfere with his education and the accumulation of knowledge.

Dr. Friedell is still at it—aiming to accumulate knowledge and that all elusive kernel of wisdom.

Isadore M. Goldberg, M.D.

Dr. Isadore Goldberg has been in active practice of medicine in Minneapolis until the last five years and since then he has limited his practice to insurance medicine.

Throughout this period he has maintained offices in the Minneapolis loop. His avocations include tennis, and he still has a hard serve to return. Dr. Goldberg is married to Blanche (Halpern). They have two children, Arthur and Dr. Stanley.

Lawrence Gowan, M.D.

Dr. Gowan was born at Ardoch, North Dakota. His father was a pioneer settler in the Red River Valley. He graduated from Park College, Parkville, Missouri, following which he entered Medical School at the University of Minnesota.

After interning at the University Hospital, he was granted a Teaching Fellowship in Nervous and Mental Diseases. Under Dr. McKinley's direction he carried out a research problem in Postencephalitic Paralysis Agitans. He received an M.S. in Nervous and Mental Diseases from the University of Minnesota in June, 1925 and was elected to Sigma Xi.

In July, 1925, Dr. Gowan entered private practice in Duluth and in 1934 he persuaded St. Mary's Hospital to establish a special department for the care of the mentally ill. He was certified by the American Board of Psychiatry and Neurology in both Neurology and Psychiatry in May 1939.

In 1937 he helped establish the Duluth Mental Hygiene Clinic and was for several years its Medical Director. In 1948 Dr. Gowan set up the Douglas County Guidance Center in Superior, Wisconsin and was its Medical Director on a part time basis until June 1971.

He served as Chief of Staff of St. Mary's Hospital and Chief of the Department of Psychiatry at both St. Mary's and St. Luke's Hospitals on several occasions.

His hobbies are gardening and fishing and he works every day hoping to put in another five years in active practice.

Bayard T. Horton, M.D.

Dr. Bayard Taylor Horton was graduated from the University of Virginia School of Medicine in 1922. After some tenure as professor of biology on a college faculty in Virginia he came to the Mayo Graduate School of Medicine in 1925, where he later was named associate professor of medicine. In 1929 he was appointed to the staff of the Mayo Clinic, a post he occupied until he retired in 1958. In 1940 he was appointed head of a section of clinical investigation. With his colleagues Dr. Horton was able to identify and describe two new disease entities: temporal arteritis (Horton's disease) and "Horton's syndrome" (histaminic cephalgia which now are standard terms in medical dictionaries. The two diseases are unrelated. Currently he is Director of Medical Research at the new Walter O. Boswell Memorial Hospital in Sun City, Arizona.

Frank J. Kucera, M.D.

Dr. Frank J. Kucera was born in McLeod County, Hutchinson Township, September 24, 1894 and attended country school, the Hutchinson High School, graduating in 1913, and the University of Minnesota from 1915 to December 15, 1921. He served on the staff of St. Barnabas Hospital for 49 years and has been an active staff member of Methodist Hospital since 1959.

He married Alma Foss of Minneapolis, 50 years ago, and they have three children and six grandchildren. Dr. Kucera loves to travel, fish and spends a great deal of his time in his gardens.

Robert F. McGandy, M.D.

Dr. Robert F. McGandy throughout his career as a surgeon, has been an active member of his local medical society and the Association. He was president of the Hennepin County Medical Society in 1950. He has been on the Association's Judicial Committee on Automotive Injuries and presently is on the Insurance Liaison Committee. Doctor McGandy was certified by the American Board of Surgery in 1945 and is an emeritus clinical assistant professor of surgery at the University of Minnesota. He is a past president of the Minneapolis Surgical Society, founding member of the American Burn Association and a Fellow in the American College of Surgeons. He was graduated from the University of Minnesota.

Maurice W. McInerny, M.D.

Dr. Maurice W. McInerny was born in Minneapolis, May 21, 1898, where he has been a lifetime resident. In active practice since graduation, he received his B.S., M.B., and M.D. from the University of Minnesota and interned at City and County Hospital, St. Paul and at St. Mary's Hospital, Minneapolis.

Married Helen Marshman, graduate nurse of St. Mary's and plans to celebrate his golden wedding anniversary, January 10, 1973. At the present time there are three daughters, nine grandchildren and one great granddaughter to make life quite worth while. Work volume has been curtailed but he has no thought to complete retirement except by public demand. He has devoted his career to general practice and hospital work in surgery and obstetrics.

Paul F. Meyer, M.D.

Dr. Paul F. Meyer has been a general practitioner and surgeon in Faribault since 1926. He is currently on the staff of St. Lucas Hospital and in 1950 was president of St. Lucas-Deaconess Hospital Medical Staff. During his years in Faribault, he has been county physician, health officer, and a member of the county board of health.

Hamilton Montgomery, M.D.

Dr. Hamilton Montgomery was graduated from the Harvard Medical School in 1922 and came to Rochester, Minnesota, in 1925, as a second-year fellow in the Mayo Graduate School of Medicine. In 1929 he was appointed to the staff of the Mayo Clinic as a consultant in dermatology, and from that time until his retirement in 1959 was privileged to devote himself to dermatohistopathology as well as clinical dermatology. He co-authored and authored three editions of *Diseases of the Skin*, with Dr. Oliver S. Ormsby; and in 1967 his two-volume *Dermatopathology* was published. His holiday hours are spent in his sailboat on the Mississippi River as a member of the Coast Guard Auxiliary.

Dr. Montgomery was vice president of the American Dermatological Association, Inc., in 1958, president of the Chicago Dermatological Society in 1938, a founder and first president of the Dermatopathological Society (1962), vice president of the Society for Investigative Dermatology, president of the Minnesota Dermatological Society and an honorary member of the New York Dermatological Society and of European dermatological societies.

C. L. Oppegaard, M.D.

Dr. C. L. Oppegaard, well-known specialist in ophthalmology and otolaryngology was awarded the Association's 1962 Distinguished Service Award. He was council chairman, 1954-60, president-elect, 1960, president, 1961, councilor and member of the House of Delegates for several terms. He was also a member of the Committee on University Relations. Doctor Oppegaard was a graduate of the University of Minnesota where he interned and completed post-graduate work. He was a Fellow of the American College of Surgeons and a member of the American, Minnesota and North Dakota Academies of Ophthalmology and Otolaryngology. Doctor Oppegaard spent his years of active practice serving Crookston.

Arthur B. Roehlke, M.D.

Dr. Arthur B. Roehlke has devoted his years of practice to Elk River. Educated at the University of Minnesota, he interned at the University and Miller Hospitals. With the Association, he served on the Committee on Trauma and was delegate and alternate delegate to the House of Delegates. He is also a past president and former secretary-treasurer to the East Central Minnesota Medical Society. He remains in practice and is surgeon for the Northern Pacific Railway.

Robert Rosenthal, M.D.

Dr. Robert Rosenthal was born in Austria and had his entire schooling in that country, including medical education. He graduated from the medical school of the University of Vienna in 1922 after having spent three and one-half years in World War I. After a half year residency in Internal Medicine at the Vienna General Hospital, one year residency in a Children's Hospital and some postgraduate work in Berlin, he came to this country late in 1923. He took his State Board Examination in 1924 and has since practiced pediatrics in St. Paul. From 1926 on he did some teaching at the pediatric department of the University as assistant demonstrator and assistant professor in pediatrics, but was inactive for a number of years before being placed on the emeritus list.

For about twenty-five years Dr. Rosenthal served on the staff of Ancker Hospital in the pediatric department and for many years was active in the Greater St. Paul Health Council. In 1961 he served as vice-president of the Ramsey County Medical Society and over half of this time as acting president.

For many years he was chairman of the Historical Committee of the Minnesota State Medical Association and during that period coordinated the medical history of many counties in Minnesota and authored a few of his own.

Dr. Rosenthal has been a member of the medical staff of the Family Nursing Service of St. Paul since 1924, being its oldest member in years of service.

Raymond J. Spurzem, M.D.

Dr. Raymond J. Spurzem is a general practitioner and has been medical advisor to the Anoka County Selective Service Board for 35 years. He has served as advisor to the County Welfare Board and as deputy county coroner. A graduate of the University of Minnesota, Doctor Spurzem interned at the University Hospitals, served on the staff of Eitel Hospital, Minneapolis, as local surgeon for the Great Northern and Northern Pacific Railways and assistant physician at the Anoka State Hospital.

Walter C. Stillwell, M.D.

Dr. Walter C. Stillwell, a surgeon for many years at the Mankato Clinic, is a graduate of the University of Minnesota and did postgraduate work there and at the University of Vienna. He is a member of the American College of Surgeons, International College of Surgeons and the American Society of Abdominal Surgeons. For several years, he was on the Association's Public Health Education Committee.

E. J. Tanquist, M.D.

Dr. E. J. Tanquist, general practitioner, was honored as one of Minnesota's leading practitioners by the Minnesota Academy of General Practice in 1953. In 1928, he built the Douglas County Hospital, approved by the American College of Surgeons. Doctor Tanquist is a diplomate of the International Academy of Proctology. Outside his medical practice, he has spearheaded many community projects. In 1972, he was elected an outstanding Kiwanian and given a life fellowship in the Kiwanis International Foundation. Doctor Tanquist remains in active practice with his son.

Owen H. Wangensteen, M.D.

A biographical sketch of Dr. Owen Wangensteen will appear in an early issue.

"What's a Sawbones?" inquired Mr. Pickwick, not quite certain whether it was a live animal, or something to eat.

"What! Don't you know what a Sawbones is, sir?" inquired Mr. Weller. "I thought everybody know'd as a Sawbones was a Surgeon."

"Oh, a Surgeon, eh?" said Mr. Pickwick, with a smile.

"Just that, sir," replied Sam. "These here ones as is below, though, ain't reg'lar thorough-bred Sawbones; they're only in trainin'."

"In other words they're Medical Students, I suppose?" said Mr. Pickwick.

Sam Weller nodded assent.

"I am glad of it," said Mr. Pickwick, casting his nightcap energetically on the counterpane. "They are fine fellows; very fine fellows; with judgments matured by observation and reflection; tastes refined by reading and study. I am very glad of it."

"They're a smokin' cigars by the kitchen fire," said Sam.*

*Charles Dickens, Pickwick Papers, Chapter XXX (1836).

if skin is infected, or open to infection...

choose the topicals that give your patient–

- broad antibacterial activity against susceptible skin invaders
- low allergenic risk—prompt clinical response

Special Petrolatum Base
Neosporin® Ointment
(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

Vanishing Cream Base
Neosporin®-G Cream
(polymyxin B-neomycin-gramicidin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 10,000 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); gramicidin, 0.25 mg., in a smooth, white, water-washable vanishing cream base with a pH of approximately 5.0. Inactive ingredients: liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax, purified water, and 0.25% methylparaben as preservative.
In tubes of 15 g.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical after-care, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. These products are contraindicated in those individuals who have shown hypersensitivity to any of the components.

Complete literature available on request from Professional Services Dept. PML.

Wellcome / **Burroughs Wellcome Co.**
Research Triangle Park

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections.

In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

In usual IV doses, Lincocin (lincomyc hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in wate But when 4 grams or more per day is given, Lincocin should be diluted in n less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

ifections caused by susceptible strains
pneumococci, streptococci, and
aphylococci, including penicillin-
sistant strains. Staphylococcal strains
sistant to Lincocin (lincomycin
ydrochloride, Upjohn) have been
covered. Before initiating therapy,
lture and susceptibility studies should
performed. Lincocin has proved
luable in treating patients hyper-
nsitive to penicillin or cephalosporins,
ice Lincocin does not share
tigenicity with these compounds.
owever, hypersensitivity reactions
ve been reported, some of these in
tients known to be sensitive to
nicillin.

ell tolerated at infusion site: Lincocin
travenous infusions have not
oduced local irritation or phlebitis,
ien given as recommended. Lincocin
usually well tolerated in patients who
e hypersensitive to other drugs.
evertheless, Lincocin should be used
utiously in patients with asthma or
gnificant allergies.

patients with impaired renal function,
e recommended dose of Lincocin
ould be reduced to 25—30% of
e dose for patients with normal
dney function. Its safety in
egnant patients and in infants
s than one month of age has
t been established.

ncocin may be used with other
timicrobial agents: Since Lincocin
stable over a wide pH range, it is
itable for incorporation in
ravenous infusions; it also may be
administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatment. *Skin and mucous membranes*—Skin rash, urticaria, vaginitis, and rare instances of exfoliative and vesiculobullous dermatitis have been reported. *Liver*—Although no direct relationship to liver dysfunction is established, jaundice and abnormal liver function tests (particularly serum transaminase) have been observed in a few instances. *Cardiovascular*—Instances of hypotension following parenteral administration have been reported, particularly after too rapid IV administration. Rare instances of cardiopulmonary arrest have been reported after too rapid IV administration. If 4.0 grams or more administered IV, dilute in 500 ml of fluid and administer no faster than 100 ml per hr. *Special senses*—Tinnitus and vertigo have been reported occasionally. *Local reactions*—Excellent local tolerance demonstrated to intramuscularly administered Lincocin (lincomycin hydrochloride). Reports of pain following injection have been infrequent. Intravenous administration of Lincocin 250 to 500 ml of 5% glucose in distilled water or normal saline has produced only local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500 mg* Capsules—bottles of 24 and 100. *Sterile Solution, 300 mg per ml*—2 and 10 ml vials and 2 ml syringe. *Syrup, 250 mg per 5 ml*—60 ml and pint bottles.

Case Report

Sino-Orbital Aspergillosis

Report of a Case and Review of the Literature

H. H. ZINNEMAN, M.D.*

USUALLY ASPERGILLOSIS is encountered in the human as an opportunistic infection in individuals with debilitating diseases, immune deficiences or recipients of immunosuppressive or antimetabolic drugs. It may appear as a saprophyte, presenting as a "fungus ball" in pulmonary cavities. Involvement of the nasal mucosa, maxillary and ethmoid sinuses without extension to the orbit may occur in individuals with unimpaired general health.[1-5] Maxillo-orbital aspergillosis has also been observed in otherwise healthy patients.

Case Report

A 46-year-old divorced Caucasian male had been subject to chronic alcoholism, which had led to chronic pancreatitis. It also manifested itself radiologically with pancreatic calcifications. A mild diabetes mellitus, secondary to this condition, had never led to diabetic acidosis or other complications, in spite of the patient's unwillingness to observe a dietary regimen. The patient presented himself because of orbital pain and rapidly declining vision of the right eye. He was an unkempt man of poor general and particularly oral hygiene. There was a continuous offensively smelling mucosanguineous discharge from the right naris. The right lower turbinate appeared swollen and gangrenous. There was a marked right ocular proptosis. Funduscopic examination showed a pale right retina. A trickle of erythrocytes could be seen in the main retinal artery. It stopped during the examination, at which time the patient stated that he could not see anything with the right eye. At the beginning of the funduscopic examination he had been able to distinguish light from darkness.

Laboratory Findings

Initial laboratory findings were as follows: *Urinalysis:* Specific gravity 1010, pH 8.0, acetone 0, glucose 3+, protein 0, microscopic examination of the sediment 0-5 WBC/HPF. *Blood:* Hb 9.0, Hct 26.5, RBC 2,910,000, MCD 7.2, WBC 9.720 (78% PMN, 22% mononuclear cells). Blood sugar 115mg/100 ml, BUN 16 mg/100 ml, Na 139, K 4.1, Cl 100, CO_2 28 meq/100 ml, cholesterol 169 mg/100 ml, SGOT 18 U. Total serum bilirubin 0.2 mg/100 ml, alkaline phosphatase 11.3 KAU.

Assuming that he was dealing with maxillo-orbital mucormycosis, the attending physician initiated intravenous therapy with Amphotericin B in doses gradually increasing to 50 mg daily. Surgical removal of the gangrenous tissue from the lower turbinate and most of the mucosa from the right maxillary sinus provided specimens of mucous membrane for histologic examination and was followed by a decrease of the exophthalmos (Figure 1). Histologic preparations of the mucosa showed chronic inflammatory reaction surrounding hyphae, which were interpreted as Mucor (Figure 2). Cultures had not been incubated at that time. While the patient received intravenous therapy with Amphotericin B to a total of 2 gm, his general status improved. His diabetes mellitus never offered a problem and was satisfactorily controlled by dietary measures. He was discharged from this hospital, but returned after 14 months, because a fistulous drainage had established itself in the right canine fossa, discharging malodorous serosanguineous exudate (Figure 3). A radial Caldwell-Luc procedure yielded additional specimens of mucosa, which were cultured. Histologic preparations were similar to the ones obtained previously, and cultures yielded

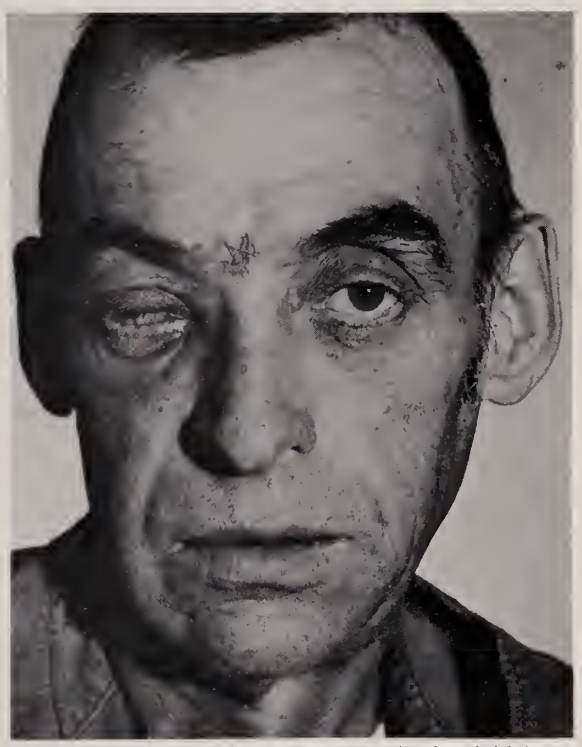

Fig. 1—Orbital involvement one week after initial surgical intervention and intravenous therapy with Amphotericin B. The proptosis has decreased but palpebral and periorbital edema is still prominent.

*Medical Service of the Minneapolis Veterans Administration Hospital and the Department of Medicine, University of Minnesota Medical School, Minneapolis, Minnesota.

Aspergillus flavus (Figure 4). There also was a small growth of *Nocardia asteroides*. Postoperatively the sinuses were irrigated with solutions of Amphotericin B. The fetor disappeared and subsequent cultures failed to grow *A. flavus* or *N. asteroides*. There has been no recurrence during 18 months of clinical follow-up observation.

Comment

Deep mycosis is one of the causes of rapidly developing exophthalmos. The geni Mucor and Aspergillus figure prominently in this clinical picture. Whereas sino-orbital mucormycosis has been observed mainly in individuals with debilitating diseases or conditions, such as diabetic acidosis, alcoholic cirrhosis, uremia, leukemia and neoplasms, similar involvement by Aspergillus usually has been observed in otherwise healthy persons.

Figure 2—Mycelial hyphae in a section of mucosa from the right maxillary sinus. H & E stain magnification X 400.

Aspergillus may involve only a maxillary sinus.[1-6] From there it may extend to the orbit, causing pain, exophthalmos and frequently amaurosis due to invasion and occlusion of the ophthalmic artery.[7-12] The Table lists the reports

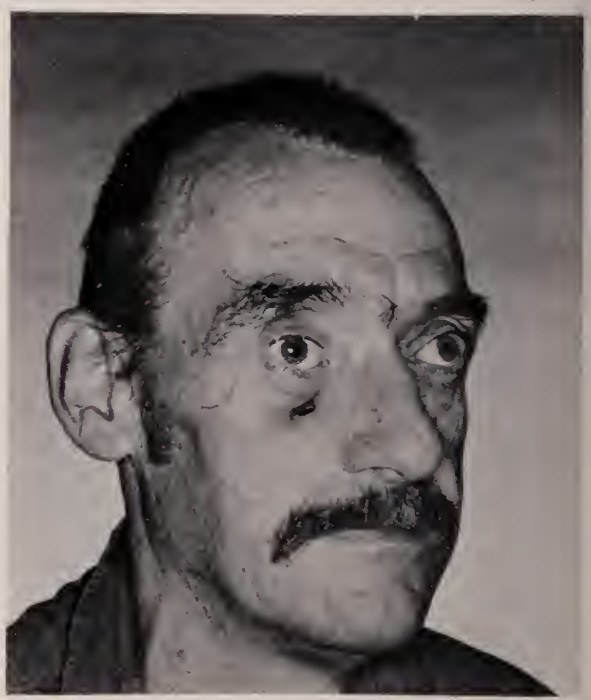

Fig. 3—Spontaneous drainage from the right orbit through a fistula in the canine fossa.

TABLE

Previously Reported Cases of Aspergillosis of Nose, Sinuses and Orbit

Author & Year	No. of Cases	Identif	Aspergillus Species	Other Diseases	Involvement: Nose	Involvement: Maxillary Sinus

Crivelli 1970	1	Histol	Aspergillus	No	—	—

of 24 cases, where this development took place. None suffered an underlying debilitating disease. Aspergillosis of the nose and a maxillary sinus was found in all patients except one. The patient without maxillary sinus involvement was reported by Crivelli.[13] A circumscribed aspergilloma at the optic foramen was the cause for his unilateral amaurosis. There was no proptosis. The clinical picture was consistent with that of a meningioma of the right optic foramen. Surgical exploration found and removed a pea-sized aspergilloma at the optic foramen, between optic nerve and carotid artery. General involvement of the orbit with exophthalmos and proptosis was the rule, where involvement of the orbit resulted in a space-occupying mass.[7-12] Therapy with antifungal agents was used in seven cases (see Table) and found disappointing. In one instance, where it represented the only means of therapy[10] the patient died subsequent to an extension of the process into the brain. In the remaining six patients antifungal therapy was considered futile, and surgical treatment resulted in improvement or cure. On the other hand, whenever surgical treatment was employed, either as sole method of treatment (28 cases), or in combination with antifungal therapy (six cases) the therapeutic results were better. Of the 34 surgically treated patients only one failed to improve, and one died. *A. flavus* was encountered more frequently than *A. fumigatus* as the pathogenic agent.

The case under discussion also was caused by *A. flavus*. The patient's diabetes mellitus was a sequence of chronic pancreatitis and never had led to complications. It was easily controlled by dietary regimens. In this respect this patient is comparable to other patients with sino-orbital aspergillosis without underlying debilitating diseases. Confirming the experiences of others, our treatment with Amphotericin B did not effect lasting results, whereas subsequent surgery was curative. It is of interest that spontaneous drainage through a fistula in the canine fossa had been

Fig. 4—Culture on Czapek agar produced a greenish-yellow growth. Conidia and conidial heads are greenish-yellow, sterigmata are short and stubby. Magnification X 440.

TABLE (Continued)

Yes	—	Blind	Surgery	Recovered	

noted in a previous case.[8] In another patient[9] spontaneous drainage from the involved orbit established itself in the temporal region, anterior to the right ear.

The experience from this patient and from review of the literature suggests the following:

1. Sinomaxillary mycosis occurring in an otherwise healthy individual is most likely due to an Aspergillus species.
2. The species involved is most likely *A. flavus* or *A. fumigatus*.
3. Antifungal therapy used exclusively is unsatisfactory. Its value as supportive therapy is uncertain.
4. Surgical removal of the involved tissue is the most promising therapy, with or without supportive antifungal therapy.
5. Surgical intervention is particularly urgent in orbital aspergillosis, where the eyesight is still preserved.

It's the Law

No Malpractice in Treatment of Hip Fracture

A 28-year-old patient sustained a fracture of her left hip as a result of an automobile collision. She was examined by her family physician and a surgeon. Xrays were taken under the supervision of a radiologists and they indicated an impacted fracture of the left femoral neck. An open reduction was performed, a Smith-Peterson nail was inserted. Xrays immediately following surgery indicated good position and alignment with the fracture and good position of the nail.

Xrays over the next several months indicated deterioration of the head of the femur. A third consultation was sought, the nail was removed and the patient was treated for several months in a spica cast. Subsequently, a girdle stone operation was carried out resulting in shortening of the leg and some stiffness.

The court ruled that no negligence had been exhibited, that the standard of care was satisfactory and that the only detectable error on the part of the physician, if it was indeed an error, was not informing the patient of the possibility of the aseptic necrosis of the femoral head at the time of the original injury.

The Chronic Alcoholic in a Small Community Hospital

JAMES J. GARBER, M.D.*

DETOXIFICATION OF the acutely intoxicated alcoholic in a general hospital setting has previously been reported,[1-8] demonstrating the feasibility of alcoholic detoxification on a general medical floor. Such a program in a small community hospital has not, however, previously been described.

Hospital treatment of the chronic alcoholic seems indicated for three reasons. First, alcoholism is a multisystem disease[9-19] and requires a general medical evaluation which can often be best accomplished in a hospital. Second, treatment of the various alcoholic withdrawal syndromes,[20] which can be severe and unpredictable, may require hospital care. Last, removal of the alcoholic from his drinking environment to begin rehabilitation is frequently necessary.

The present study was undertaken to establish the workability of such a program in a small community hospital.

Materials and Methods

All patients admitted for alcoholic detoxification to the medical service of the Olmsted Community Hospital from August 1967 to September 1970 were included in this study. The Olmsted Community Hospital is an 85-bed general hospital. During the period of this study there were 10,630 admissions.

Admission policy was patterned after the guidelines of the American Medical Association's Commission on Alcoholism and Drug Dependence for admission of such patients to a general hospital.[21]

Incidence

Of the 10,630 admissions, 85 were for alcoholic detoxification. Seventy-seven patients were involved in the 85 admissions. These represented 0.8% of the total hospital admissions. Seventy patients were admitted once, six patients twice, and one three times. There were 2.3 admissions per month. The average hospital stay was 6.8 days; the average stay for a medical patient was 7.4 days.

Age and Sex

Sixty-seven patients were men and 18, women, a ratio of 3.5 to 1. The average age at time of admission was 50.3 years, approximately the same for both sexes.

Occupation

In the group there were 14 priests, which indicates a bias introduced by the opening in Rochester, during the study period, of Guest House, Inc., a treatment center for alcoholic priests. There were 14 housewives, 12 construction or maintenance workers, seven farmers, four unemployed persons, three executives, one physician, one lawyer, one nurse, and 25 patients with other occupations. Seven of the patients in the study were retired.

*Internist, Olmsted Medical Group, Rochester.

Presented as part of the seminar "The Treatment of the Hospitalized Alcoholic" sponsored by the Mayo Clinic and the Zumbro Valley Medical Society.

Withdrawal Syndromes and Complications

Withdrawal syndromes included tremulousness in 73 patients, hallucinosis in seven, and delirium tremens in five.

Medical complications included hepatic coma in three patients, seizure in one, and cardiac arrest in one (with successful resuscitation). One patient developed severe cirrhosis, and one patient bled from esophageal varices. Four patients died —two in hepatic failure, one with severe cirrhosis, and one of an intracranial hemorrhage.

Associated Medical Problems

Laboratory studies revealed significant abnormalities in 75 of the 85 patients. These included evidence of liver disease in 61 patients, six of whom had liver biopsies. The remainder had abnormal liver function tests or hepatomegaly, or both. Thirty-seven patients had abnormal electrocardiograms, non-specific repolarization abnormalities representing the most frequently seen change. Twenty-two showed evidence of a lipid abnormality: elevated cholesterol, triglyceride, or abnormal lipoprotein electrophoretic patterns. Fifteen had abnormal chest x-rays, one of whom showed active tuberculosis by culture; 12 were diabetic; 12 had some urinary abnormality such as a urinary-tract infection, proteinuria, or depressed creatinine clearance; and seven showed evidence of obstructive lung disease.

Other abnormalities included anemia, electrolyte imbalances, evidence of alcoholic myopathy, peptic ulcer disease, and a colonic polyp. Only six patients required psychiatric consultation, one was diagnosed as schizophrenic, and the remainder had neurotic disorders.

Nursing Care Problems

Extra nursing care was required for 12% of the patients. The conditions necessitating the extra nursing care included incontinence, terminal liver disease, pneumonia, and delirium tremens. One patient required extra care for a Blakemore tube and two required cardiac monitoring. Twenty-seven per cent needed a moderate degree of nursing care for such problems as occasional incontinence, mild confusion, frequent requests for medications, bed care for personal hygiene, and help with eating and walking. The remaining 61% required only minimal care: they fed themselves and took care of their own personal hygiene. Five patients left against medical advice and five confused patients wandered outside their rooms or attempted to climb over side rails, requiring additional nursing vigilance. Two patients needed restraints. Most were in private rooms. There were no management problems that necessitated male nurses or aides.

Economic Liability

In general, the patients or their insurance companies paid the hospital costs promptly. Of the 77 patients, 79.2% paid their bills in full or were paying regularly; or payment was by public welfare or Medicare. We received partial payment of 10.4% of bills, which included those for patients whose insurance company or Medicare paid a portion of the hospital costs though the patient had not contributed subsequently. About 6.5% of the bills were written off or put into collection accounts.

Discussion

When this study was undertaken, there was some apprehension: among the hospital medical staff, that they would be inundated with admissions for chronic alcoholism; among the nursing staff, that they would be faced with difficult nurs-

ing problems (both professionally and physically); and in administration, that this would represent a financial liability. It is apparent that the alcoholic patient constitutes none of these problems.

In addition, the high association of general medical disorders with chronic alcoholism was confirmed. These medical problems have often necessitated hospitalization and, in the past, alcoholic patients have been admitted without recognition of the basic disease process. The diagnosis of alcoholism was, therefore, neglected; and so was its therapy.

Though no long-term alcoholism-treatment program exists at the Olmsted Community Hospital, an attempt is made in each case to initiate a contact with the Alcoholism Information Center and Alcoholics Anonymous. Patients are started on a program using the facilities available in Rochester, are referred to an alcoholism treatment center for a more intensive rehabilitation program, or, if necessary, are committed for therapy at the State Hospital at Willmar, Minnesota.

It is hoped that this study will help dispel the concept of the "skid-row" alcoholic, frequently seen in a city-county hospital setting, and bring recognition of the problems of the more conventional alcoholic who lives in both urban and rural areas, spans the whole of the socio-economic scale, and whose care can be successfully managed in a community hospital.

Cervical Cancer Mortality Study

The past several decades have witnessed substantial improvement in the overall outlook for cervical cancer patients. Presently, two-thirds or more of all squamous cell carcinomas of the cervix are diagnosed while still in-situ and at a time when the prognosis for cure, if proper treatment is carried out, approaches 100%. While the absolute number of invasive cancers of the cervix in the United States appears to have remained relatively stable for the past 20 years, during the same time the incidence rate in Connecticut has decreased by more than 40% and in British Columbia and New York by more than 50%.

Among patients with invasive cancers of the cervix, only about 50% of such cases have disease classified as "localized" at the time of diagnosis. The overall 10 year relative survival rate for patients with clinical cancers of the cervix is reported to be slightly higher than 50%.

Thus, although it would appear that efforts of the past several decades for earlier detection of cancers of the cervix have been remarkably successful in terms of reducing the incidence rates of invasive cervical cancer, and efforts for more effective therapy have been productive of improvements in long-term survival for those with cancers diagnosed after invasion has occurred, women continue to die of this disease. In fact an estimated 9,400 will die of cancer of the cervix in the United States and probably about 100 in Minnesota this year. This is not a good record for a disease that theoretically is 100% curable!

Because of the seeming availability of methods and facilities to permit almost all cervical cancers to be diagnosed and treated while early enough to be potentially curable, and because deaths from cancer of the cervix continue to occur in Minnesota as well as in the rest of the nation, a project is currently underway to study the circumstances associated with the course of the disease in each instance in which a cure was not achieved and the cancer caused the death of the patient. This study will include all deaths from cancer of the cervix reported as occurring during the period from 1 January 1971 to 31 December 1972. Areas of deficiency in diagnosis, care, and follow-up will be delineated and studied.

This cancer mortality study was undertaken by a special subcommittee functioning under the auspices of the Obstetrics, Gynecology and Maternal Health Committee of the Minnesota State Medical Association, with the joint sponsorship of the Minnesota State Department of Health, and with the approval and endorsement of the Minnesota Division of the American Cancer Society, the Minnesota Obstetrical and Gynecological Society, the Minnesota Society of Clinical Pathologists, the Cancer Committee of the Minnesota State Medical Association, the Council of the Minnesota State Medical Association, and the Northlands Regional Medical Program.

The study committee will be known as the Cervical Cancer Mortality Committee, and will be directly responsible for the conduct of the study including the formulation of a suitable protocol of items of inquiry and review of all data prior to formal presentation of periodic reports to the sponsoring organizations. The Committee will include professional persons conversant in the areas of gynecologic oncology, gynecologic surgery, radiation therapy, public health, pathology, vital statistics and in the family practice of medicine.

The study of the circumstances of each death from uncontrolled disease will be initiated by working retrospectively beginning with the physician who signed the death certificate.

The collection of data will be accomplished by suitable professional people knowledgeable and experienced in detection, diagnosis and treatment of gynecologic malignant disease. On-the-site review of physician and hospital records and interviews with involved physicians and surviving relatives will be conducted. Pathology and cytology specimens will be reviewed and modes of therapy will be evaluated.

The Cervical Cancer Mortality Committee will assemble and review the data, assess the progress of the study, and initiate modifications or improvements as indicated. At the end of the study a summary of the activities and findings of the Committee will be presented to the sponsoring groups.

The information relating to the patients studied regardless of source, will be used solely for the purposes of this Study and is held strictly confidential under Minnesota law (Subdivision 1 of Section 144.053) and is not admissible before any court or other tribunal.

(Continued on page 674)

T_4 IS THE PREDICTABLE HORMONE BECAUSE IT LOVES PROTEIN.

SYNTHROID® (sodium levothyroxine) is pure synthetic T_4, the major circulating thyroid hormone. It is reliable to use because of its affinity for protein-binding sites in the blood. T_3 is more fickle. Sometimes it binds. Sometimes it doesn't. T_4 more *predictably* binds to protein.

Synthroid®
(sodium levothyroxine)

ALL THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID THERAPY.

No calculations are needed, test interpretation is simple.

Any of the commonly used T_4 thyroid function tests (P.B.I., T_4 By Column, Murphy-Pattee, Free Thyroxine) are useful in monitoring patients on T_4 because they *all* measure T_4. Patients on SYNTHROID are thereby easy to monitor because their results will fall within predictable, elevated test ranges. Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient.

TWO GOOD REASONS WHY THE ROAD TO NORMALIZED THYROID STATUS IS SO SMOOTH FOR THE SYNTHROID PATIENT.

(1) The onset of action of T_4 is gradual. It has a long in vivo "half-life" of over six days. (Occasional missed doses or accidental double-doses are of le concern because of this factor)[1]; (2) since SYNTHROID contains on T_4, the potential for metabolic surges traceable to more potent iodides (T_3) is eliminated.

1. Latiolais, C. J., and Berry, C. C.: Misuse of Prescription Medications by Outpatients, *Drug Intelligence & Clin. Pharm.* 3:270-7, 19

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T_4 By Column	Less than 3 mcg %	7-9 mcg %
T_3 (Resin)	Less than 25%	27-35%
T_3 (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5 nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

Choose the Smooth Road ...to thyroid replacement therapy

WHY DOES SYNTHROID COST LESS THAN SYNTHETIC DRUGS CONTAINING T_3?

e simple. T_3 costs more to make hetically than does T_4. So it is nomically necessary for a hetic thyroid medication aining T_3 to cost more than containing T_4 alone. Synthetic binations cost patients nearly more than SYNTHROID[3] use the T_3 costs more to start ; also there is the additional nse of formulating a tablet aining two active ingredients.

erican Druggist BLUEBOOK, March, 1971.

KNOWLEDGE OF THE '70's CHALLENGES CUSTOMS CONCERNING DESICCATED THYROID DRUGS.

In the past, desiccated thyroid produced from animal glands was considered "good, and cheap." We now know that improved products are available and the price difference has narrowed to the point of being inconsequential. (SYNTHROID, for instance, costs patients about a penny a day more than brands of desiccated thyroid.)

What does this additional $3.65 a year buy the patient? Quite a bit in terms of quality, reliability and service.

SWITCHING PATIENTS TO SYNTHROID IS EASY.

Switching present patients to SYNTHROID (or starting new ones) is a simple matter. SYNTHROID is available in the widest range of dosage strengths of any thyroid drug. Seven scored, color-coded tablet strengths are available plus a lyophilized injectable form for emergency or postoperative uses.

RESPONSE, RELIABILITY, SERVICE—COMPARISON OF FIVE PARAMETERS

ARAMETERS	DESICCATED THYROID U.S.P.	SYNTHROID® (sodium levothyroxine)
OURCE OF HORMONE	Animal glands (swine, sheep, cows). Hormone content of glands and ratio of T_3-T_4 varies by type of animal, season in which gland is harvested, and diet of animal.[1,2,3,4,5]	Synthetically derived pure crystalline hormone. Because no animal protein is present, no objectionable odor occurs upon aging.
ENERAL ASSAY TECHNIQUE	"Its major disadvantage is inadequate standardization of hormonal content."[8]	Unlike desiccated thyroid U.S.P., thyroxine does not require biologic standardization to establish its potency.[2,6] Crystalline T_4 is used. Purity is verified by paper chromatography. Content of tablets is standardized by weight.
LINICAL RESPONSE	"T_3 and T_4 ratio varies according to gland source. Fluctuations in response can occur. Potency can vary."[3]	"Sodium levothyroxine has been extensively used with satisfaction and is widely held to be superior to (desiccated) thyroid."[7] "There are well documented examples of patients who failed to respond satisfactorily to desiccated thyroid but subsequently responded to (sodium-1) thyroxine."[4]
REDICTABILITY	Failure of thyroid U.S.P. treated patients to show clinical improvement and/or lack of correlation in clinical findings to thyroid function test results has been frequently discussed in the literature.[8,9,10,11,12,13,14,15,16] Regardless of which factor or factors accounts for this phenomenon the fact remains that discrepancies do occur.	Test results predictably elevated. ". . . oral potency of this material is attested to by a uniformly good clinical response corroborated by a prompt and sustained increase in the serum PBI levels."[16]

PATIENTS CAN BE SUCCESSFULLY MAINTAINED ON A DRUG CONTAINING THYROXINE ALONE.

Thyroxine (T_4) is, as you know, the major circulating hormone produced by the thyroid gland. T_3 is also produced, in smaller amounts, and is active at the cellular level. For years it has been a working hypothesis among endocrinologists that T_4 is converted by the body to T_3. In 1970 this process, called "deiodination," was demonstrated by Braverman, Ingbar, and Sterling[2]. T_4 does convert to T_3, though the precise quantities are still being studied.

The conversion has been clinically demonstrated during the administration of T_4 to athyrotic patients. Their thyroid status is normalized on SYNTHROID alone, yet the presence of T_3 in these patients has been clearly shown.

CONSIDERATE LONG-TERM THERAPY FOR THE PATIENT.

Predictable patient response, of course, is more important than price. You do get complete clinical response with the single-entity synthetic, SYNTHROID. And, at a reasonable cost to the patient. In some short term situations, T_3 drugs can be useful but, in long term therapy, the smooth road provided by SYNTHROID may be the better route.

SYNTHROID, with its smooth road to complete thyroid replacement therapy, has been selected for more patients in the United States and Canada than any other brand of thyroid medication.

***Thyrolar (#1 tablet) contains 50 mcg. of T_4 and 12.5 mcg. of T_3.

Synthroid®
(sodium levothyroxine)

Indications: SYNTHROID (sodium levothyroxine) is specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or antithyroid drugs. Indications for SYNTHROID (sodium levothyroxine) **Tablets** include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (nontoxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) **for Injection** is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdosage may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting and continued weight loss. These effects may begin after four or five days or may not become apparent for one to three weeks. Patients receiving the drug should be observed closely for signs of thyrotoxicosis. If indications of overdosage appear, discontinue medication for 2-6 days, then resume at a lower dosage level. In patients with diabetes mellitus, careful observations should be made for changes in insulin or other antidiabetic drug dosage requirements. If hypothyroidism is accompanied by adrenal insufficiency, as Addison's Disease (chronic subcortical insufficiency), Simmonds's Disease (panhypopituitarism) or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The drug should be administered with caution to patients with cardiovascular disease; development of chest pains or other aggravations of cardiovascular disease requires a reduction in dosage.

Contraindications: Thyrotoxicosis, acute myocardial infarction. **Side effects:** The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism; sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction of dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and Administration: The activity of a 0.1 mg. SYNTHROID (sodium levothyroxine) TABLET is equivalent to approximately one grain thyroid, U.S.P. Administer SYNTHROID tablets as a single daily dose, preferably after breakfast. In hypothyroidism without myxedema, the usual initial adult dose is 0.1 mg. daily, and may be increased by 0.1 mg. every 30 days until proper metabolic balance is attained. Clinical evaluation should be made monthly and PBI measurements about every 90 days. Final maintenance dosage will usually range from 0.2-0.4 mg. daily. In adult myxedema, starting dose should be 0.025 mg. daily. The dose may be increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second two weeks. The daily dose may be further increased at two-month intervals by 0.1 mg. until the optimum maintenance dose is reached (0.1-1.0 mg. daily).

Supplied: Tablets: 0.025 mg., 0.05 mg., 0.1 mg., 0.15 mg., 0.2 mg., 0.3 mg., 0.5 mg., scored and color-coded, in bottles of 100, 500, and 1000. Injection: 500 mcg. lyophilized active ingredient and 10 mg. of Mannitol, N.F., in 10 ml. single-dose vial, with 5 ml. vial of Sodium Chloride Injection, U.S.P., as a diluent. SYNTHROID (sodium levothyroxine) **for Injection** may be administered intravenously utilizing 200-400 mcg. of a solution containing 100 mcg. per ml. If significant improvement is not shown the following day, a repeat injection of 100-200 mcg. may be given.

THE FACTS ARE CLEAR AND HERE IS OUR OFFER.

Synthetic thyroid drugs are an improvement over animal gland products. Patients, even athyrotic ones, can be completely maintained on SYNTHROID (T_4) alone. Thyroid function tests are easy to interpret since they are *predictably* elevated when the patient adheres to SYNTHROID. Of all synthetic thyroid drugs, SYNTHROID is the most economical to the patient.

OFFER: AA

Free TAB-MINDER medication dispensers to start or convert all your hypothyroid patients to SYNTHROID. Free information to physicians on role of thyroid function tests in a new booklet titled: "Guideposts to Thyroid Therapy." Ask us.

CLINICAL DIRECTOR to administer the medical aspects of a progressive 1,200 resident facility for the mentally retarded. Will be responsible to the Superintendent for all aspects of the clinical service and supervision of staff. Specialists in pediatrics, neurology or internal medicine will be preferred. Board certification is desirable. Eligibility for Michigan licensure required. Salary ranges from $29,211 to $36,372 with starting salary dependent on qualifications. Housing currently available at nominal cost. Excellent fringe benefit and retirement program through Michigan's outstanding Civil Service. The facility is located in a small, progressive community in lower Michigan which provides a style of life many would like to recapture yet it is close enough to cities such as Saginaw, Flint and Detroit to provide the shopping, entertainment and cultural life of the big city. To apply send vitae to the Superintendent, Caro State Home and Training School, Caro, Michigan 48723.
AN EQUAL OPPORTUNITY EMPLOYER

FAMILY PHYSICIAN needed to replace member (taking G. P. Teaching position) of five Family Practice group in Robbinsdale, suburb of Minneapolis, Minnesota. Active family practice includes medicine, pediatrics, surgery and OB, utilizing two nearby hospitals. Salary one year, full partnership thereafter. Contact: Robert F. Avant, M.D., 3819 West Broadway, Minneapolis, Minnesota 55422 Phone: 533-2534.

BAYPORT, MINNESOTA—Ideal location for general practitioner. Partially equipped office, two blocks from St. Croix River. Fully accredited hospital three miles away. Site of Andersen Corp., largest wood window manufacturer employing 1600. Retired physician practiced 48 years in Bayport. Physicians in nearby community will backup physician for any vacation time or attendance at meetings, etc. Excellent potential for one or two physicians. Contact: Keith R. Clements (612) 439-5195.

GENERAL PRACTITIONER—County seat community of 2000. Modern 35 bed hospital 4 blocks from fully equipped clinic. Present associate retiring January 1, 1973. Early partnership. Contact H. A. Knoche, M.D., Gaylord, Minnesota 55334. Telephone 612-237-2528.

WANTED: Locum Tenens—August 15 to October 1st. General Physician. Prefer Southeastern Minn. Wisconsin and Minnesota licenses. Write: Bruce Krueger, M.D., 116-1 Tangley Road, Minot AFB, N.D. 58701.

PART TIME, set your own daytime weekday schedule, central Minneapolis, $20 (more if specially qualified) hour. Write: Minnesota Medicine, Box 470, 375 Jackson St., St. Paul 55101.

Meetings

The 32nd Annual AMA Congress on Occupational Health will be held at The Drake Hotel in Chicago, September 11-12, 1972. Contact Dr. Henry F. Howe, AMA, 535 North Dearborn Street, Chicago for further information and reservations.

Southern Minnesota Medical Association Meeting, September 23, 1972, in Austin, Minnesota.

The 10th Annual Cancer Chemotherapy Conference will be held at the University of Wisconsin, Madison, on September 6-8. The program will include a review and forward look at anti-cancer therapy, multiple drug therapy of solid tumors and leukemias, the role of x-ray therapy, immunology and virology in the treatment of cancer. For information contact Dr. G. Ramirez, 714C University Hospitals, Madison, Wisconsin 53706.

Fracture Conference

Comminuted Intra-Articular Distal Radial Fractures

Dr. Einer W. Johnson, Jr.:

Comminuted intra-articular fracture of the distal end of the radius can be a challenging problem to the orthopedist.

Case 1

Dr. Charles P. Fina:

A 23-year-old man fell on his outstretched left hand, sustaining an injury to the distal end of the radius. He had a "silver-fork deformity" but no impairment of his nerve or vascular functions. The Xray (Figure 1A) showed an obvious deformity of the distal portion of the radius, with comminution and intra-articular extension of the fracture.

Dr. Johnson:

Some comminuted distal radial fractures penetrate the radiocarpal joint. This one had a fracture line that went directly into the joint and, like many fractures of this type, the fracture line was more visible after reduction than before. Note the disruption of the articular cartilage.

Dr. Fina:

The fracture was manipulated under local anesthesia, with longitudinal traction and counteraction. It was brought out to length, and good restoration of the radial angle was accomplished (Figure 1B). The volar tilt was about neutral. The patient did well in his cast.

Dr. Johnson:

The lateral fragment of the radius was a large single piece. The comminution occurred toward the ulnar joint side, and the joint line was well restored by the reduction. Significantly in these cases, the largest fragment in the comminution will almost always be on the lateral side of the distal fragment.

Dr. Fina:

The comminution in this case involved the medial fragment, which is true in up to 85% of comminuted fractures of the distal radius. This type was described by Scheck[1] and is caused by forcing the lunate into the distal end of the radius.

The patient's cast was changed at three weeks. Position was maintained, and another cast applied for two additional weeks. The Xray at six weeks after fracture (Figure 1C) showed a good anatomic result. The patient still had some residual discomfort in his wrist but had good dorsiflexion and volar flexion. There was a slight limitation of ulnar and radial deviation, but supination and pronation were full.

Dr. Johnson:

Case 1 represents a moderately comminuted fracture of the distal radius in which reduction and its maintenance were satisfactory. The patient had some loss of motion and some pain two and one-half months after fracture.

Case 2

Dr. Fina:

A 38-year-old man fell six feet from a ladder onto his outstretched hand, with immediate pain in the wrist and paresthesias in his thumb and index finger. Radiographic examination revealed (Figure 2A) comminution of the radius distally, as well as intra-articular extension of the fracture.

Dr. Johnson:

Just as in Case 1, there was comminution at the level of the distal radio-ulnar joint, the almost completely intact lateral portion of the distal fragment, and the invasion of the joint by the fracture line. However, this patient was treated differently.

Dr. Fina:

Closed reduction was attempted under local anesthesia, and a fair reduction was obtained. However, as the patient had severe pain and paresthesias in the distribution of the medial nerve, the position of the wrist had to be altered. When this was done, the position of the fragments was lost. He was taken to the operating room the following day and underwent release of his carpal canal because of severe and persisting carpal-tunnel symptoms. At the same time, a Kirschner wire was inserted into the metacarpal at the thumb, a cast was applied, and traction was exerted through the metacarpal of the thumb.

Dr. Johnson:

The reason for the skeletal fixation was to try

Fracture Conference April 14, 1969.

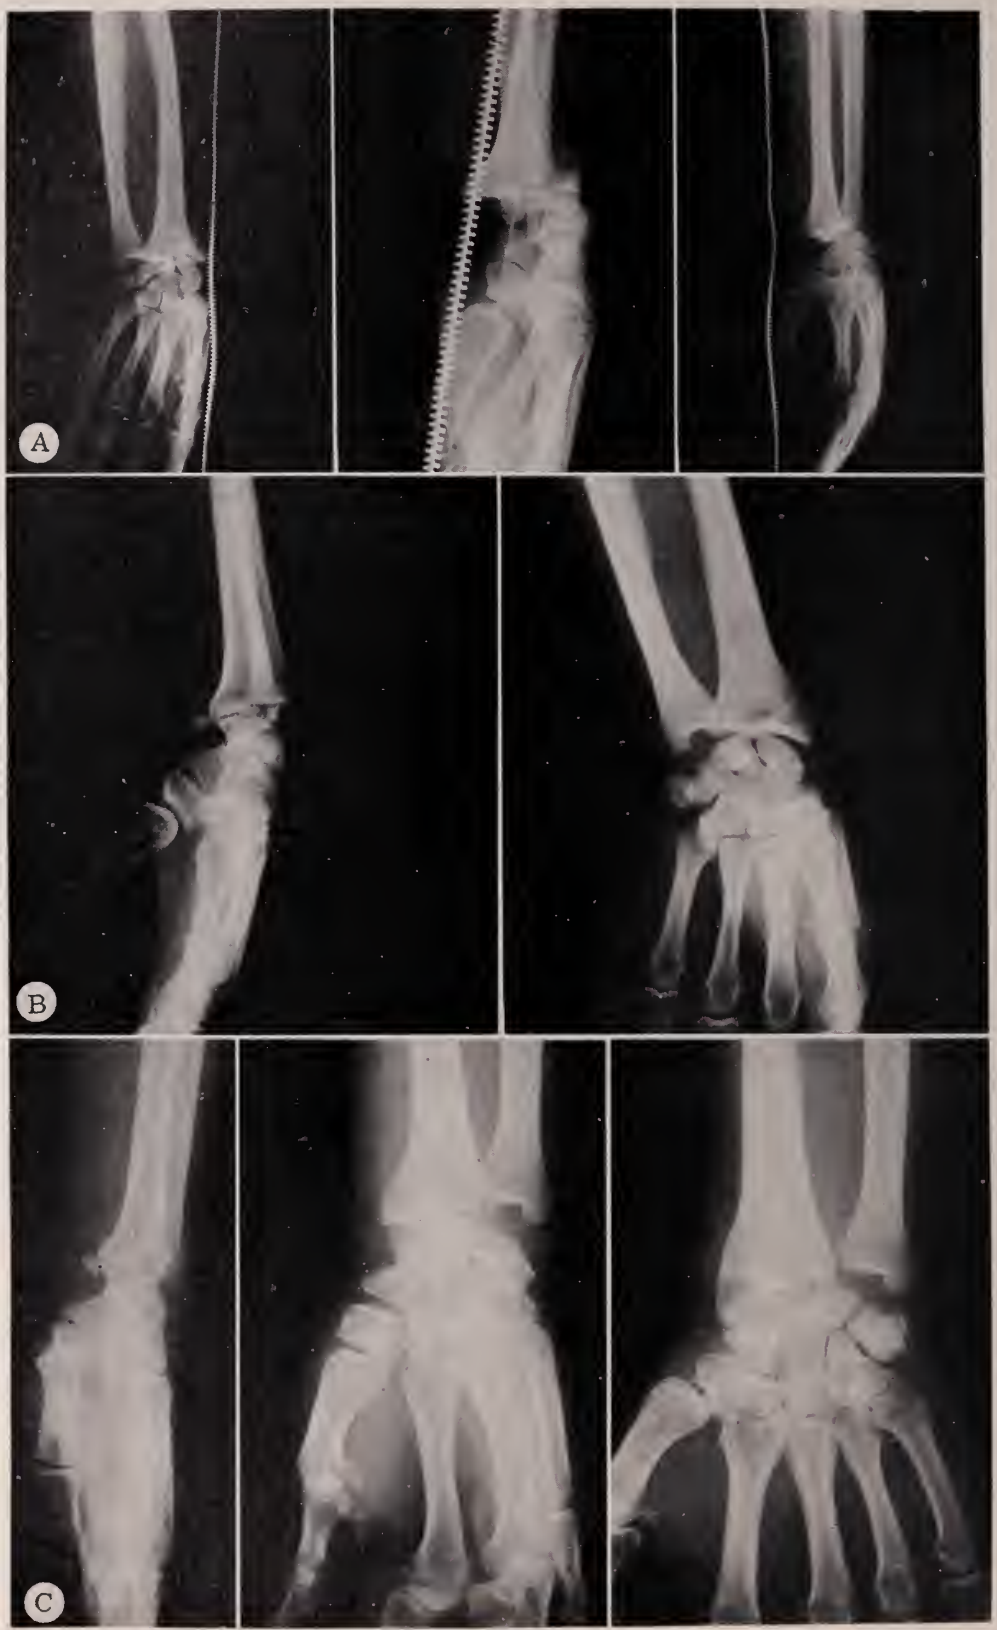

Fig. 1—Comminuted, intra-articular fracture of distal radius. (A) Sept. 1, 1968. Anteroposterior and lateral views show significant medial comminution, reasonable intact lateral cortex, and dorsal shift of carpus. (B) Sept. 18, 1968. Anteroposterior and lateral view show excellent reduction, with maintenance of radial length, radial and volar angles. (C) Oct. 14, 1968. Anteroposterior and lateral views show final healed position, with excellent anatomic result.

Fig. 2—Comminuted, intra-articular fracture of distal radius. (A) Dec. 15, 1968. Initial anteroposterior and lateral views reveal severe comminution, intra-articular extension, and dorsal shift of carpus. Comminution is more medial than lateral. (B) Dec. 18, 1968. Anteroposterior and lateral views reveal loss of reduction (shortening, dorsal tilt, and shift) despite skeletal traction. Patient had subsequent manipulative reduction in an attempt to gain an improved anatomic position. (C) Feb. 20, 1969. Final anteroposterior and lateral views show loss of volar angle and radial length, with good radial angle. This was an excellent functional result.

to maintain length and keep the fracture from collapsing. The wound healed per primum.

Dr. Fina:

The patient was brought to the operating room five days later, and the wound was inspected and found to be healing. Pin traction (Figure 2B) was kept in place, and "sugar-tongs" splints were applied. However, four days later, the position had slipped and length was lost. His radio-ulnar joint was remanipulated again under general anesthesia.

Dr. Johnson:

Our efforts to maintain reduction and to maintain length again failed.

Dr. Fina:

Position was lost. His radio-ulnar joint was manipulated and the pins were removed at this time.

Dr. Johnson:

We agreed to accept that position. He was a young man of 38 years, and he still had satisfactory radial length in relation to the ulnar length and a reasonable angle to the articular surface of the distal radius (Figure 2C). He had a modest radial shift of the hand; but the shift was not enough to be striking, and he was happy with his result. Although the anatomic result was not perfect, the functional result was acceptable.

Case 3

Dr. Fina:

An elderly woman fell on her outstretched left hand. She had had a Colles' fracture of the same wrist 14 years before. Physical examination showed the typical deformity of the wrist. We have some Xrays showing her wrist in the reduced position. (Figure 3A).

Dr. Johnson:

There was comminution that involved the joint, a good deal of shortening, and a completely intact lateral aspect of the distal fragment. Comminution was toward the ulna, bordering on the distal radio-ulnar joint.

Dr. Fina:

In the position of palmar flexion and ulnar deviation, length was lost. The patient also had some

Fig. 3—Comminuted, intra-articular fracture of the distal radius. (A) Mar. 10, 1969. Initial anteroposterior and lateral views show severe comminution and intra-articular involvement and severe shortening. (B) Mar. 13, 1969. Anteroposterior and lateral views reveal improved length and position three days after casting. However, shortening and loss of volar and radial angles are still apparent. (C) Apr. 25, 1969. Six weeks after fracture and external skeletal pin and plaster fixation. Further collapse has been prevented, but anatomic position has not been obtained.

symptoms of median-nerve compression, although not nearly as severe as that seen in Case 2. She was operated on under general anesthesia, three days after the fracture. After longitudinal traction had been instituted (Figure 3B), skeletal pin transfixation was instituted using Kirschner wires through the second and third metacarpals and through the middle of the radius (Figure 3C). The wires were incorporated in a plaster-of-paris cast because of the severe distal comminution and collapse and because of our inability to maintain this position without some form of transfixation.

Comment

Dr. Johnson:

The types of comminuted fractures of the distal radius that we have been discussing violate the joint and are problems not only in reduction but also in maintenance of reduction, particularly maintenance of length. Dr. Fina has a few comments on the pertinent literature.

Dr. Fina:

In 1814 Abraham Colles[2] published his treatise on fracture of the carpal extremity of the radius: a fracture generally considered extra-articular. Colles[2] believed that almost all patients got a satisfactory result. Other writers[3] who examined their series of cases critically and objectively, with definite criteria, found much less favorable results. In one group, Gartland and Werley[4] noted unsatisfactory results in 68.3% of 60 patients. They also noted that the type of fracture affected the ultimate outcome. Comminution or intra-articular extension (or both) generally yielded poor results. Residual deformity had a direct relationship to poor reduction and an unsatisfactory end result. Sixty percent of their patients eventually ended up in premanipulation position if they had been treated with plaster-of-paris below-elbow casts or with "sugartongs" splints. This was particularly true when comminution and intra-articular extension were present.

In an analysis of 2,000 patients with Colles' fractures, Bacorn and Kurtzke[5] found that only 3% of patients had no disability and that there was an average disability of 24% of the entire arm. Again, residual deformity and impaired function were in direct relationship to each other. However, 96% of the patients with distal radial fractures were satisfied with their results after conservative treatment. This indicates that subjective results are much better than objective results. Again, the percentage of unsatisfactory results increases with comminution and intra-articular extension[6].

The three criteria that we should use to measure the success of the reduction are: (1) radial length, (2) radial angle, and (3) volar angle, all of which are disturbed when comminution is present. A combination rather than one single deformity causes loss of good function or form.

Adequate maintenance of reduction in a comminuted fracture can be accomplished with skeletal transfixation and incorporation into a plaster-of-paris cast. This may be one of several forms. Ulnar pinning of the distal fragment, as advocated by DePalma[7], has yielded excellent results. Cole and Obletz[8] utilized a Kirschner wire, transfixing the second and third metacarpals and the radius. Scheck[1] inserted one Kirschner wire through the second and third metacarpals near the base and placed another through the proximal end of the ulna. Both wires were incorporated in a circular plaster-of-paris cast. Finally, Carothers and Boyce[9] advocated skeletal traction through the first metacarpal for maintenance of reduction. I would tend to favor the methods of Scheck[1] and of Cole and Obletz.[8] The advantages are (1) maintenance of reduction, (2) ablation of the deformity, (3) improved function, (4) shorter rehabilitation time, and (5) avoidance of future surgery. We can anticipate satisfactory results in as many as 85% of the patients so treated.

Dr. Johnson:

In the comminuted Colles' fracture, as many as 70% of patients have poor anatomic position after reduction and without internal fixation. When you discuss Colles' fractures, do not confuse objective with subjective results. In any series, 96 or 97% of patients are satisfied with the result. Most of these are older people for whom neither cosmesis nor function is a problem; if their wrist works and does not hurt, they are satisfied. I think that it is a fallacy for the physician to analyze results by the X-ray appearance alone.

In the comminuted fracture that involves the radiocarpal joint, there are three problems: (1) loss of radial length, (2) loss of ulnar tilt, and (3) supination of the distal fragment. The average inclination of the articular surface in the anteroposterior plane should be about 23°, and there should be about 11° of volar tilt of the articular surface

on the lateral view. These, plus supination of the distal fragment, are the deformities that are caused by the fracture. Correct these and you should have a good result. However, you cannot maintain reduction in the comminuted fracture with plaster alone. Transfixation is usually necessary.

Dr. Richard S. Bryan:

The point has been made about comminution on the distal radius and its effect on the ultimate health of the radiocarpal joint. The wrist must be kept in some ulnar deviation in the plaster because this is the only way that the normal curve of the distal radial articular surface can be restored. This is the "bow" where the lunate rests.

Dr. James H. Dobyns:

The large lateral radial fragment is not always intact, as DePalma[7] has said. When this happens, we have tried DePalma's method, only to be thwarted by a split in the lateral fragment. In this case, the two-pin method would have worked well.

Dr. Johnson:

In summary, the following points can be made: 1. Comminuted fractures of the distal radius are more common than is believed. 2. The comminution is customarily near the distal radio-ulnar joint, usually penetrates the radiocarpal joint, and leaves the distal lateral aspect of the radius as one large intact fragment. 3. Although reduction is easily accomplished because of the comminution and the presence of intact ligaments and the joint capsules, maintenance of the reduced position is difficult. 4. Without some form of skeletal fixation, various degrees of loss of position are inevitable. 5. In our experience, two-pin skeletal fixation incorporated in plaster has worked well and painlessly in maintaining reduction.

Now it is certain, that the radical heat lives in the radical moisture, but whether *vice versa*, is a doubt: however, when the one decays, the other decays also; and then is produced, either by an unnatural heat, which causes an unnatural dryness—or an unnatural moisture, which causes dropsies.—So that if a child, as he grows up, can but be taught to avoid running into fire or water, as either of 'em threaten his destruction,—'twill be all that is needful to be done upon that head.*

*Laurence Sterne, Tristram Shandy, Book V Chapter 36, 1762.

History

Chekhov, the Physician

EDMUND C. BURKE, M.D.*

PHOTOGRAPHS OFTEN show Doctor Chekhov fashionably dressed in the mode of the late 19th century with starched collar, cravat, long black coat, pince-nez glasses, and neatly trimmed goatee. He was six feet tall, thin, almost gaunt, sandy-haired, hazel-eyed, and serious in appearance. It was said that there was "no cast to his eye of the fiery revolutionary." His nature was modest and unpretentious. The nearly 600 articles and four famous plays† he wrote attest to an incredible amount of work for a life of only 44 years; such an outpouring represents an article every other week for 25 years. In addition this young man who died at 44 was a physician. When could he have found time to practice medicine and what kind of practitioner was he? How did he regard medicine as a career? How did his medical background influence his writing?

The career of Chekhov, the physician, is little known because it was so eclipsed by his literary brilliance.

The Family

Anton was the second oldest in a family of five boys and a girl.[1] He was born, in 1860, in Tagenrog, a grubby little port town on the Sea of Azov, near Rostov. His father, while possessing some talent as a choirmaster and musician, was a small shop owner and a tyrant as a parent. Anton, with his brothers, had to work in the store, do his lessons at night, and arise early in the cold, dark morning to sing in church services. He stated later in life that his childhood was no childhood. There was talent in the family, to be sure, inasmuch as his siblings became authors or teachers and one became an artist, albeit an alcoholic. None of the children embraced religion in later life, a reaction predictable under the circumstances.

When the father's business failed, the family moved to Moscow where Anton joined them at the time he was ready to enter medical school. Clues to his nature and temperament can be found in his childhood. He loved the theater and proved to be so skillful at mimicry that he amused his boyhood friends with his antics. He wrote, directed, and acted in comic plays of one or two acts. He was truly a comic, possessed of a rollicking sense of humor. This same frivolity pervaded his early writings. He employed humor rather than ridicule; he was satiric but not sardonic.

Medical Education and Early Practice

Chekhov was fascinated by Doctor Shrempf, a village physician who treated him for a serious illness, at age 15, which may have been tuberculous peritonitis. Chekhov's mother provided him with much encouragement to pursue medicine as a vocation and to help support the family during his medical days, he wrote short articles, most of which were comic sketches. During these years (1880-1884) he wrote nearly 300 under the pseudonym, Antoshe Chekonte.[2]

Anton graduated from the University of Moscow in June 1884 and went to the Chikino Hospital as a practicing physician. His first patients had a bad tooth, dysentery, and a stomach ailment, respectively, and these cases earned him a total of 14 rubles in fees. He promptly blew all this in a party for his friends. This love of friends and gaiety was typical of his life. On one occasion, when faced with a screaming child in need of a minor operation, he was forced to summon a senior colleague because he did not feel equal to the situation.

As a rural physician he was confronted with festering sores, diarrhea, and tapeworms as well as the poor diet and ignorance of the peasants and a dull village life. This routine did little to challenge his great talents. He did express the belief, however, that the practice of medicine seemed a surer way to support himself than literature. After trying two weeks at a locum tenens in Zvenigorod he was happy to escape to Moscow where he hung out his shingle.

*Mayo Clinic and Mayo Foundation: Department of Pediatrics, Rochester.

†The Seagull, Uncle Vanya, The Three Sisters, and The Cherry Orchard.

Reprint requests address to: Dr. E. C. Burke, Mayo Clinic, Rochester, Minnesota, 55901.

In the winter of 1884 he experienced the first hemorrhage from his throat (pulmonary) which was a prelude to his death 20 years later from tuberculosis. Like many physicians he refused to consult his medical colleagues (nearly 13 years elapsed before he placed himself completely under medical care).

In Moscow he had many literary acquaintances who imposed on his medical knowledge but paid him little or nothing in fees. His interest in medicine inclined toward the scientific aspects and at one time he considered writing a thesis for a higher degree. The meagerness of his income was a result of his inability to charge patients for service rendered. A lack of money and the need to support his family were still concerns in his early days. He was not wasteful in money matters but he often entertained most hospitably.

The following summer in Chikino he treated hundreds of peasants for minor ills for a total income of one ruble. He would write and practice medicine in the morning, hunt in the afternoon, and write and practice again in the late afternoon and evening. In one of his letters in 1887, he mentioned having attended a thousand patients during the previous year.[3]

He stated[4,5] that medicine was his lawful wife and literature was his mistress; when he would grow weary of one he would spend the night with the other. His story "Name Day Party" was based on an obstetric case and proved to be very popular with women for its accurate depiction of the problems and the anguish of childbirth.

Growing restless, he hit on the idea of traveling across Siberia in the spring of 1890 to the prison colony on the island of Sakhalin to investigate the living conditions of the prisoners, a journey which proved to be very hazardous. He spent the months of July through October collecting data through interviews. On file in the Moscow Lenin Museum are 10,000 cards, each of which has 13 entries, attesting to the thoroughness of his investigation. Of course, he had to have official sanction for this visit and undoubtedly he had some clerical help. The results of this study, published in 1893, were impressive and this work has been termed a shining example of a research thesis. The incredibly horrible conditions which existed were described so vividly by Chekhov that he was able to bring about some prison reforms.

Melikhovo

For seven years (1891-1898) Chekhov found a happy and congenial home at his 500-acre estate in Melikhovo. Anton personally planted many fruit trees, planned the garden, and became endeared to the peasants who flocked to him with their ills. In 1892 he had accepted a position as a member of the Sanitary Commission[5] responsible for a section of the province threatened by a cholera epidemic. He showed great executive ability in organizing the hospital, and he often drove about the territory day and night to see patients. He built three schools in Melikhovo and gave his moral and financial support to a new journal, *The Surgical Chronicle*. He also proposed, supported, and supervised the building of a community library.

The following letter[6] (translated from Russian by the author) from Chekhov's sister, Marya, is evidence of Chekhov's avowed pride in his vocation in medicine.

Yalta
6 October 1953

Dear Comrade Geizer!

I completely support your view that Anton Pavlovich always was interested in the practice of medicine and never turned away from the work of a physician. Truly, he esteemed his social position as a physician. You may also have read in the recollections of many contemporaries how Anton Pavlovich always maintained that he was a physician. You may even state that on moving from Melikhovo to Yalta, Anton Pavlovich gave as a gift almost his entire library to the city of Tagenrog, taking with him to Yalta only his most beloved books at the same time taking all of his medical books, even those lectures which he at one time studied at the University. And, if you read his letters, remember how he worked for preservation of the journal "Surgery" etc.

Are you acquainted with the book of Khizhnyakov "Chekhov as a Physician"? There the theme is the same as you have taken. (The book was published five years ago.)

I wish you success. Good health.

Yours.
M. Chekhov

Yalta

In 1898 because of his failing health and the insistence of his physician, he sold the Melikhovo estate and built a villa on the hills above Yalta. This home is now a museum dedicated to him and his life. He continued to devote time to the sick, many of whom were consumptives from all over Russia. He took an active part in education and for his efforts he was awarded the Stanislav medal. He raised money and directed efforts to

construct and equip a tuberculosis sanatorium. He worked in his gardens where he was often photographed with his dogs in his moments of relaxation. The last six years of his life were very fruitful despite his illness—during this period he wrote five plays, one of which was *The Seagull*, staged by Stanislavsky in the Moscow Art Theatre.

Very little is known of his romantic interests in life because there is little or nothing in his letters to indicate more than a passing interest, let alone a major romantic attachment. Olga Knipper, by then a famous actress in the Moscow Art Theatre, consented to marry Anton in May 1901. The couple lived together very little since Olga's theatrical career kept her in Moscow, and Anton could rarely leave Yalta because of his failing health.

In January 1904, Chekhov attended the successful first performance of *The Cherry Orchard* in Moscow. He was obliged to return to Yalta after a few months. For his deteriorating health it was recommended that he travel to Badenweiler in the Black Forest. Three weeks later he died, on July 2, 1904, at the age of 44. His wife survived him until 1958.

The Nature of His Works

Chekhov's early works were frivolous and light buffoonery.[4,7] He fabricated ridiculous names, often symbols of the characters depicted. His later works turned satiric and were concerned with social problems. Hospital scenes and physicians figured prominently in his stories. His perceptiveness was acute, but his medical training probably honed to a keenness this talent for recognizing moral frailties, banalities, stupidity, and cupidity of his fellowmen.

His work does not reflect scorn, because he viewed human nature with a charitable eye, the mark of a compassionate physician. Unlike Tolstoy and Dostoevsky, Chekhov had a sense of humor, and through the pages "satire, sadness, gaiety and grief go hand in hand . . ."[7] Like a true realist he was able to see all sides of life, an ability he recognized in himself, and this may have been why he regarded psychiatry as appealing.

Of his many short stories, *Ward 6* interests me as a physician. This chilling portrayal of social conditions in Russia during the 19th century reveals the unspeakable deprivation, inhumanity, cruelty, and degradation of the peasantry. The tale of this mental hospital with its filth, uriniferous odors, bathtubs filled with vegetables, and brutal and dishonest ward attendants has been called a microcosm representing the social conditions existing in Russia 70 years ago.

The influence of his training as a physician is apparent in Chekhov's story *Typhoid Fever* which is an excellent clinical sketch. In *The Dual* two types of physicians are portrayed, one, an army surgeon, is appealing in his service to others but the second is more a usurer than a clinician. In *Three Years,* a young woman is operated on for cancer which later recurs. *Ionitch* depicts a rural practitioner who is rejected in marriage but builds a large practice and later rejects the same woman when she speaks of matrimony. In *Uncle Vanya,* Doctor Astrov works night and day and regards life as a nuisance, stupid and dirty, but endangers himself when he visits a village where typhus is endemic.

Chekhov on Medicine

On the occasion of his 25th anniversary as a writer, Chekhov wrote in a medical journal: "Medicine is my occupation, and to such a degree, in fact, that some time during the year I perform more forensic medical dissections than I once completed in two or three years."[7]

On another occasion he wrote: "I have no doubt that the study of the medical sciences has had an important influence on my literary work; they have considerably widened the range of my observations, and enriched me with knowledge, the true value of which to me, as a writer, can be understood only by one who is himself a doctor."[8]

Chekhov stated; "My family name and my crest I have given to medicine which I shall not desert for the rest of my life."[2] To Bilibin he said; "Sooner or later I shall part with literature."[2]

The Nature of the Man

Doctor Chekhov appears as an appealing man and the fact that he chose medicine as a vocation indicated his interest in human welfare and perhaps his need for human contact. He did not retreat from the demands of his patients because of aversion to human suffering but rather because of his restlessness and creative spirit which demanded other means for fulfillment.

He cherished friends and at times he entertained in a fashion too extravagant for his means. He was not immoderate in drink, had no publicized passionate or elicit romances, and was not obsessed with wealth despite his impoverished early years.

He was stubborn, sometimes obstinate, but showed none of the irascibility or temper tantrums of Dostoevsky. Impatient and demanding of himself, he seldom mistreated his friends, nor is there any evidence that he was anything but a considerate physician to his patients. He dealt with servants, waiters, porters, and simple folk with gentleness.

Kuprin,[9] a Russian author, stated that Chekhov had "incomparable spiritual firmness and beauty . . . the most beautiful, refined, and spiritual face I have ever seen in my life . . ."

His sister was devoted to him and proved to be a wise and efficient manager of his estate. She felt jealous and displaced when Anton married Olga Knipper but this did not affect the friendship between Anna and Olga.

Thomas Mann[10] noted that Anton was irritated by the imperial and prophetic airs of Tolstoy. Chekhov wrote: "To devil with the philosophy of the mighty ones of this world! All sages are as despotic as generals and as rude as generals, convinced as they are of impunity."[10] This outburst was occasioned by Tolstoy's denunciation of physicians as "useless scoundrels."

Mann[10] maintained that Chekhov suffered from honorable sleeplessness, feeling responsible for human fate. "What are we to do?" was a question often uttered by Chekhov. To Chekhov, Dostoevsky's work was "good but immodest and pretentious." From these reflections we can imagine that Chekhov suffered much from an enormity and depth of conscience.

The entire cast of *The Cherry Orchard* came from Moscow to perform for him at Yalta,[8] surely a magnificent display of love and respect. This play and Stanislavsky's genius combined to make the world aware of the Moscow Art Theatre.

Solzhenitsyn* is the most popular Soviet author outside the USSR and it is interesting to compare him with Chekhov for his portrayal of conditions within the Soviet Union. *Cancer Ward* has great similarity to *Ward 6* in depicting the suffering, humiliation, and despair of patients in a ward for those with malignant tumors. Because of the criticism implied of the Soviet system and because his works have been published in the West, Solzhenitsyn is not recognized but is a non-person in the USSR.

Although he never wrote a novel, Chekhov is ranked with Pushkin by Pasternak for "his child-like Russian quality and shy reticence." He deserves acclaim from physicians for his dedication to medicine. It is true that he spent little time in the practice of medicine but spent much time with patients when he was not writing. He was dedicated to the needs, physical and emotional, of his fellow man.

*Recently awarded the Nobel Prize in literature.

OPERATIVE TREATMENT OF BONE TUMORS. 3rd International Symposium, January 24th-26th, 1969 in Basle, Switzerland. Edited by George Chapchal. Stuttgart, Georg Thieme, and New York, Intercontinental Medical Book Corporation, 182 pp, 1970.

This is a collection of the papers presented at the Orthopaedic Department of the University of Basle. The participants are to be congratulated on setting aside time to discuss this most important aspect of orthopedics. Such an effort has not been evident on the North American continent in recent years.

In the section on pathology and diagnosis, a most interesting study was one by F. J. Makai and A. Belan emphasizing the prevalence of the spread of primary bone tumors by lymphatic routes. One table suggests that positive lymphograms are associated with a shorter survival time in patients with malignant bone tumors.

The remainder of the text is devoted to results of treatment, case presentations, and methods for excision of tumors and reconstruction of the resulting defects. The methods are varied and reveal courage and surgical ingenuity. One participant reported his experience with excision of the distal femur or proximal tibia and replacement with homotransplants preserved at —30 C or in polymer briquettes. Another investigator described his results after resecting the tumor-containing bone, irradiating the bone with Co^{60}, and then re-implanting the bone segment.

The symposium is interesting and is directed to the orthopedist whose main interest is orthopedic oncology.

Rochester, Minnesota

RESPIRATORY PHYSIOLOGY. Second Edition. By N. B. Slonim and L. H. Hamilton, C. V. Mosby. St. Louis. 1971. 230 pp. $10.75.

CARDIOVASCULAR PHYSIOLOGY. Second Edition. By R. M. Berne and M. N. Levy. C. V. Mosby. St. Louis. 1972. 265 pp. $9.25.

These two slim segments of clinical physiology are updated versions of first editions that appeared in 1967. *Respiratory Physiology* is written for the non-physiologist especially for the clinician, frankly, I think, for graduate students about to be examined in the field. It is a useful primer of respiration for all clinicians. One should not quarrel with the physiology but one might question the almost clinical statement that is made in the book that healthy trained subjects never experience true dyspnea. I have had many patients describe their cardiac dyspnea as shortness of breath just like the sensation after running only it occurs with much less exertion. *Cardiovascular Physiology* has a front cover illustration of the left ventricular pressure curve and one lead of the electrocardiogram. In a sense the whole book is an elaboration of the implications of these two curves. The great changes wrought in the past five years in cardiology are manifested in the majority of references which are in work, published since 1967. Both books merit perusal by all students whether or not they are about to be examined for degree or diploma.

Reuben Berman, M.D.
Minneapolis, Minnesota

TEXTBOOK FOR THE ORTHOPAEDIC ASSISTANT —F. R. Schneider, C. V. Mosby Co., Price: $10.75.

This textbook is clearly written and well illustrated and indexed. The basic aspects of musculoskeletal development and physiology are adequately described, and the terminology used to describe fractures and other musculoskeletal conditions is well covered. The "whiplash" injury to the neck is a lay term, however, and its use should be discouraged by those involved in treating cervical spine injuries. Plaster and traction techniques are superbly explained and illustrated and the fundamentals of orthopedic history taking and physical examination described. The importance of close observation of patients in Bryant's traction is stressed. Rewrapping of both legs daily in an attempt to prevent serious vascular complications should also be emphasized.

Although written for the orthopedic assistant, this book offers much information that is useful to the medical student, general practitioner treating orthopedic problems, and the orthopedic resident early in his training.

Lee C. Detenbeck, M.D.
Rochester, Minnesota

EMPHYSEMA by Fred A. Obley, M.D. published by Beacon Press, Boston. Price: $7.50, 116 pages.

This is an excellent book for patients suffering from emphysema and could be well recommended by the physician who has numerous occasions to treat this disease.

Carl O. Rice, M.D.
Minneapolis, Minneosta

SYNOPSIS OF DERMATOLOGY by Wm. D. Stewart, M.D.; Julius L. Danto, M.D.; and Stuart Maddin, M.D. October 1970. The C. V. Mosley Company, $13.85.

This second edition of Synopsis of Dermatology is an excellent book for both students and practitioners. The text is divided into four sections. The first deals with the development, structure, and function of the skin. Second, the office practice of dermatology is discussed. Regional diagnosis is next covered, while the final section describes individual diseases.

Discussion of the various dermatologic conditions are by necessity short in a book of this length (pp 445). However, the descriptions are adequate and well written. In addition, many of the newer concepts in both diagnosis and treatment of dermatologic disease are covered. The authors, for each disease, include a clinical description, differential diagnosis, and treatment. It should be noted that this book is well illustrated with many color plates, most of which are of excellent quality. This book should be of value for those interested in clinical dermatology.

Farrell S. Stiegler, M.D.

AUGUST, 1972

Section 1 of Two Sections

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counselin

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

ROCHE
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

BECAUSE ALLERGIES ARE A YEAR-ROUND THING.

NOVAHISTINE® LP

DOW PHARMACEUTICALS

rheumatoid arthritic blowup...

Tandearil® Geigy

oxyphenbutazone NF tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Patients should discontinue the drug and report immediately any sign of: fever, sore throat, oral lesions (symptoms of blood dyscrasia); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.
Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.
Contraindications: Children 14 years or less; senile patients; history or symptoms of G.I. inflammation or ulceration including severe, recurrent or persistent dyspepsia; history or presence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypertension; thyroid disease; systemic edema; stomatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent chemotherapeutic agents, or long-term anticoagulant therapy.
Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh initially unpredictable benefits against potential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.
Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.
Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angiitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goite association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

99% allergen-free air is here

If you wrote a prescription for 100% allergen-free air, we'd come within 1% of filling it. We're the ultra-clean air people. We're Dexon, Inc. — makers of Prime-Aire® Purifiers.*

Man's most efficient air filtering method

Heart of the Dexon Prime-Aire is a HEPA (High Efficiency Particulate Air) filter six inches thick. This is the absolute filter. The most efficient ever developed. It's structured from a dense, sophisticated glass fiber media developed originally for the Atomic Energy Commission to remove airborne radioactive contaminants.

Effectiveness

Prime-Aire's HEPA filter has an efficiency of 99 percent in removing particles 0.5 micron (one micron equals 1/25,000 of an inch) and larger. This includes bacteria, smoke, and fumes. It has even greater efficiency for larger particles, removing essentially 100% of such airborne allergens as dust, pollen, molds and yeast cells.

Operating mode

Prime-Aire's two-speed blower system draws in ambient air through the Dexon-designed pre-filter. This removes large airborne contaminants. Virtually all remaining airborne microorganisms are trapped in the HEPA filter's convoluted folds. Air flowing from the front of the unit is now in excess of 99% allergen-free. A controlled air velocity of 100 feet per minute assures quiet, draft-free operation.

Choice of Units

Two portable models are available. The illustrated Prime-Aire console model purifies the air in an average 1200 square foot home at least once an hour. This model is 18″ x 18″ x 22″ high and weighs 35 lbs.

Our table model (not shown) filters the air in a 12′ x 12′ room five times an hour. It is 18″ wide by 14″ deep by 9″ high, and weighs only 18 lbs. Both models are UL listed.

Easy care

The HEPA filter needs no washing. It's replaced about once a year if used continually. And less often if used seasonally. The pre-filter is replac monthly during continuous use.

Ordinary purifiers can't compare

Prime-Aire must not be confused with elect static devices. The Dexon HEPA filter never ne cleaning. Electrostatic filters require frequent moval and washing. Prime-Aire's filtering effici cy is rated at 99% and beyond. Average repor efficiency of electrostatic devices is 85%. Prin Aire provides whisper-quiet operation. There's arcing, snapping or ozo gas as generated by elect static methods.

Dexon's history of contamination control

Purifying air is nothi new to Dexon. Nor is it sideline with us. We've be at it for nearly 12 yea Dexon ultra-clean air wo stations are on the job hospitals. Also pharmace tical labs, food processi plants, microelectronic co ponent firms and wherev contamination-free air zon are required. There's a re son: Dexon systems cons tently meet or exceed Cl 100 conditions of Fede Standard 209a for clean roo and work station requiremen

Allergy sufferers breathe something ra

With Prime-Aire, many allergy patients have proven weapon to fight — and often prevent their suffering and discomfort. When breathi Dexon's ultra-clean air, many of these people r port a degree of relief they never before thoug possible.

An aid in many places

In promoting a healthful environment, Prim Aire has uses that go beyond the home. It's al ideal for doctor's offices, consulting rooms, nu ing homes — to name just a few places.

Medical data

To obtain documented performance data, wri Dr. I. A. Ismail, Director of Medical Produc Dexon, Inc., 3440 Belt Line Blvd., Minneapol Minn. 55416. Phone: (612) 927-5671.

*Patents Pending

President's Letter

Nothingness?

YOU STAND, with some other physicians, as your name and state are intoned from off stage and for approximately four blinding seconds you are spotlighted. Thus each state and territorial medical society is officially recognized at the American Medical Association's President's Inaugural ceremony.

Representing the Minnesota State Medical Association on that occasion was similar to an experience of nothingness in miniature. Visually isolated from all around you, auditory sensation dulled by the sameness of the repetitious calling of the roll, no tactile awareness of others. Hello! Is anyone out there. The spotlight shifts to the next and then the next until all are so honored. Your eyes accommodate applause marks the cessation of the droning roll call, you are jostled by your neighbors when sitting down on the crowded platform. You are once again with humanity and it's a welcome relief.

Isolation is unpleasant for most of us. I, for one, am uncomfortable when insulated from my colleagues. My first two letters to you dealt with the humanness of medicine as a profession in our contacts with each other as well as with our patients, and about changes occurring in our State Association and the American Medical Association. It has been rewarding and instructive to receive some response concerning those subjects. Visual, auditory and tactile insulation from Minnesota physicians is something your president is determined to avoid.

Hello! Is there anyone else out there?

George B. Fratus

"The history of science, and in particular the history of medicine...is... the history of man's reactions to the truth, the history of the gradual revelation of truth, the history of the gradual liberation of our minds from darkness and prejudice."

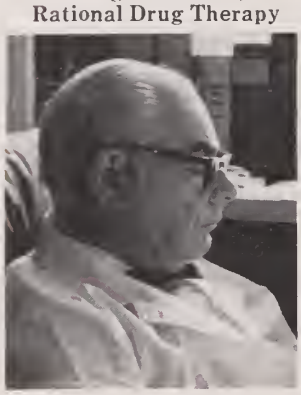
—George Sarton, from "The History of Medicine Versus the History of Art"

Would it be useful in clinical practice to have government predetermine drugs of choice?

Opinion

Results of a survey of physicians:

13.3%
Yes, it would be useful.



86.7%
No, it would not be useful.

Dialogue

Would it be useful in clinical practice to have government predetermine drugs of choice?

Doctor of Medicine

Walter Modell, M.D.,
Professor of Pharmacology,
Cornell University
Medical College,
Editor,
Clinical Pharmacology
& Therapeutics,
Drugs of Choice,
Rational Drug Therapy

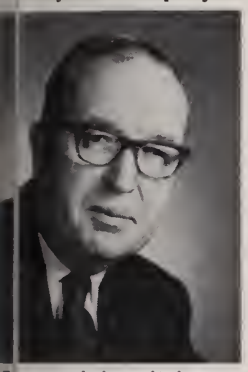
The proposition that government should determine one or two "drugs of choice" within a given therapeutic class reflects the belief that a similarity in molecular structure insures a close similarity in pharmacologic effect. But this is by no means the rule. An obvious example would be in the field of diuretics, where a small change in chemical structure accounts for substantial differences in concomitant effects such as potassium excretion.

Any attempt to dictate the "drug of choice" would be complicated by the fact that some populations demonstrate a bimodal distribution in their reaction to drugs. If the data on drug response are mixed for the total population, one drug will appear to be as useful as the other. But if drug response is reported separately for different segments of the population, drug A will be found to be better for one group and drug B for the other.

It may, of course, be possible to determine drugs of choice in particular categories on a broad statistical basis. But there are always certain patients in whom a drug produces odd, unpredictable or idiosyncratic reactions. So, though a drug might statistically be the most useful one in a given situation, individual variations in response might make it the *incorrect* one.

The point I wish to make is that if two, three, four or more drugs in one class are of approximately equal merit, that in itself is justification for their availability. Exceptional cases do arise in which one drug would be useful to a certain segment of the population and another drug would be of no use at all. In the practice of medicine, the physician must be prepared to treat the routine as well as the unusual case.

Another objection to the determination of a drug of choice is that precise statements of *relative* efficacy are very difficult to make—much more difficult than statements of efficacy. For example, in testing drug efficacy, it is easy to determine the difference between a drug that is effective in treating a condition and one that is not at all effective. Thus, it is fairly easy to determine whether a drug is more effective than a placebo. But if you compare one drug that is effective with another drug that is also effective, and the relative differences between them are very slight, statements of relative efficacy may be very difficult to make with assurance.



I do not mean to imply that relative efficacy statements are not useful or can never be made. With some groups of drugs (e.g., analgesics), extensive study and precise methodology have yielded useful information on relative efficacy. But in most situations, such information can be acquired only through studies encompassing three to five years of use in many more patients than are used to compare drugs with a placebo for the introduction of a drug into commerce. It is really only after practitioners use a drug extensively that relative safety and efficacy in practice can rea determined.

The Bureau of Dru suggested the packa sert as a possible me communicating inform on relative efficacy of to the physician. I fin objectionable, since not believe the phy should have to rely o source for final sci truth. There is also a tical objection: Sinc physicians actually pense drugs, they s see the package inse any event, I would tain that the phys should know what dr wants and why witho pending on the gover or the manufacturer him.

Undoubtedly, physi are swamped by exc numbers of drugs in therapeutic categories I am well aware that drugs within such te gories could be elimi without any loss, or e haps even some prof the practice of medi But, in my opinion, ne the FDA nor any o single group has the e tise and the wisdom n sary to determine th "drug of choice" i al areas of medical practi

Maker of Medicine

n·th G. Kohlstaedt, M.D.,
Vice President,
Medical Research,
E Lilly and Company

I my opinion, it is not e nction of any governe or private regulatory e y to designate a "drug c ice." This determina- ı hould be made by the ıcian after he has re- i l full information on e roperties of a drug. n en it will be based on s xperience with this u and his knowledge of e ndividual patient who s king treatment.

I n evaluation of com- ar ive efficacy were to be a , particularly by gov- n ent, at the time a new u is being approved for a eting, it would be a r disservice to medi- n nd thus to the patient t consumer. For exam- e hen a new therapeu- t ent is introduced, on e asis of limited knowl- g it may be considered more potent, more f tive, or safer than r ucts already on the a et. Conceivably, at i time the new drug ı be labeled "the drug ıoice." But as addi- ı l clinical experience is c nulated, new evidence a become available. a , it may be apparent that the established products should not be so easily dismissed.

Variation in patient response to drugs constitutes one of the major obstacles to the determination of "drugs of choice." We are just beginning to open the door on pharmacogenetics, but it is evident that genetic differences cause wide variations in the way drugs are absorbed, metabolized, etc. This fact alone is sufficient to make unrealistic the idea that there is one drug in each class to be used for every human being.

The problem of determining relative drug efficacy is an extremely complicated one. Comparison with other drugs of the same class should not be a prerequisite for marketing a new substance. In some therapeutic areas, it may be difficult to make accurate comparisons. For example, in the treatment of infections it is not possible to conduct crossover studies. Recovery may be influenced by factors which cannot be controlled or measured, i.e., natural host resistance and virulence of infective agents. A drug's acceptability must often be judged on the basis of its own performance, and this may be limited to experience in a relatively small patient population. If the introduction of a new drug must await the adequate establishment of relative efficacy, the duration of clinical trial and extent of studies would be greatly prolonged, particularly for rare or unusual conditions. The availability of a new drug would be delayed. Many patients might suffer needlessly and lives might be lost.

Relative efficacy can best be established by experience in a general patient population through regular channels of clinical practice. The physician considers the patient as a whole, which means the patient often has multiple problems and drugs must be selected with this in mind. Hence, a "drug of choice" in an uncomplicated case may not be the best drug for a patient with associated problems. Publication of well-controlled studies in medical journals may provide comparative evidence; discussions at medical meetings, presentations at postgraduate courses, and the new audiovisual technology may bring evidence to physicians on comparative therapy. In a free medical marketplace, a drug that does not measure up will fall into disuse. For example, broad clinical experience has established vitamin B_{12} as the "drug of choice" for the treatment of primary pernicious anemia. No amount of advertising or promotional effort by the manufacturer could increase the use of liver extract for this anemia. However, a physician may wish to employ parenteral liver preparations for a special purpose.

In the field of surgery, peer review in the hospital has brought significant improvement in the use of new techniques and procedures. Something of this nature would be useful in the area of drug therapy. However, it should be developed by the medical profession itself and would necessitate, for its proper function, an improvement in the dissemination of reliable data on clinical pharmacology of drugs under consideration.

Ideally, information on the relative efficacy of drugs should be gathered and assessed by the physicians who actually administer the specific agents to a specific patient population. To do this, they will need even more information on the drugs they use — information that the pharmaceutical manufacturers must begin to provide if government regulation of *"drugs of choice"* is to be avoided.

Familial Idiopathic Hypoparathyroidism

With Superficial Moniliasis, Pernicious Anemia and Addison's Disease

RONALD OLIN, M.D. and MARLIN H. POINDEXTER, M.D.

FAMILIAL MULTIPLE ENDOCRINE deficiencies are being reported with increasing frequency. Because they can be associated with such diseases as superficial moniliasis, pernicious anemia, Hashimoto's thyroiditis and steatorrhoea, a great number of clinical presentations are possible. The demonstration of circulation serum auto-antibodies to endocrine glands, intrinsic factor and parietal cells of the stomach suggests an inherited abnormality in the immunologic mechanism accounting for all these findings.

This report describes two sisters with idiopathic hypoparathyroidism and chronic mucocutaneous moniliasis, one of whom also had "adult-form" pernicious anemia and Addison's disease and the other serum adrenal auto-antibodies. Their mother and a younger sister have auto-antibodies to gastric mucosa. Their father, a brother and another sister are normal.

Pernicious anemia of the "adult-form" is extremely uncommon before age 20; our patient is the sixth reported case documented by modern methods. The combination of idiopathic hypoparathyroidism, superficial moniliasis, pernicious anemia and Addison's disease in a patient has been described only once previously.[1]

Report of a Family

Parents

Both are of Scandinavian ancestry, unrelated and are presently in good health. There is no other known family history of endocrine deficiency or pernicious anemia. In 1964, both had normal Schilling tests. The mother's serum reacted to gastric mucosa but not to thyroid microsomes or adrenal cortex (Table 1).

Jerome

Born 2-24-50. He had normal growth and development. As of August, 1971, he had no signs of endocrine deficiency, pernicious anemia or superficial moniliasis.

Linda

Born 10-30-51. She had Thrush in infancy. In January, 1958, she developed parasthesias of the hands and feet and carpopedal spasm. A positive Chvostek's sign was noted. The serum calcium was 8.6 mg.% and phosphorus 6.6 mg.%. These became normal when vitamin D and calcium gluconate were started. In January, 1959, hypoplastic teeth with deficiency of enamel were noted. In January, 1963, she became pale and weak. Her hemoglobin was 5.2 gm.%, hematocrit 16 vols.%, leukocyte count 6,000 per cmm. with a normal differential and the platelet count 80,000 per cmm. She had a histamine-fast achlorhydria. Her bone marrow examination showed a megaloblastic erythrocytosis with large metamyelocytes. A Schilling test revealed 1.8% excretion before and 18.1% excretion of labeled Vitamin B_{12} after intrinsic factor. Vitamin B_{12} injections were started and the hemoglobin soon rose to normal. In 1964, her left thumbnail showed moniliasis. The moniliasis was successfully treated with Fungizone lotion.

Additional studies at that time revealed a low serum iron and high latent iron binding capacity, a normal gastric mucosal biopsy except for the absence of parietal cells, normal thyroid function and no evidence of malabsorption. Serum studies revealed the presence of auto-antibodies to gastric mucosa and adrenal cortex. The parents were

advised to watch for Addison's disease.

In November, 1968, an eruption caused by T. gypsum developed on both elbows. The eruption cleared up with Griseofulvin therapy. Medications at this time were calcium gluconate two tablespoons daily, vitamin D 100,000 units daily and vitamin B_{12} 100 micrograms intramuscularly monthly.

She was seen again on January 4, 1971, with a four month illness consisting of weakness and weight loss of 50 lbs. (235 to 185 lbs.). She was hypotensive, and her skin had a brownish tinge. Plasma cortisols were 1 microgram at 8:00 a.m. and 3:00 p.m., and 24 hour urine for 17-Ketosteroids and 17-ketogenic steroids was 0.9 mg. and 0.6 mg., respectively. Serum sodium, chloride and blood sugar were moderately reduced and serum potassium was normal. She improved with intravenous saline infusions and parenteral steroids and was dismissed from hospital one week later on Cortisone acetate 10 mg. thrice daily and Florinef 0.1 mg. once daily. She has been well on follow-up examinations, her latest in August, 1971.

Veronica

Born 5-11-53. Frequent upper respiratory infections were present in childhood. In August, 1957, a convulsion occurred during a respiratory infection. Chvostek's sign was positive, carpopedal spasm was present. Serum calcium was 6.2 mg. % and phosphorus 10.4 mg. %. The Elsworth-Howard test indicated hypoparathyroidism. Calcium gluconate and vitamin D were started with a good response.

In 1964, she was noted to have mycotic fingernails, thrush, bilateral semiptosis, and healed keratitis. Mycostatin oral suspension and Fungizone lotion were prescribed. Serum iron was low and the latent iron binding capacity high; thyroid function was normal; Schilling test and gastric mucosal biopsy were normal. There was no evidence of malabsorption. Her serum contained auto-antibodies to adrenal cortex but as of August, 1971, no signs of adrenocortical insufficiency had developed.

Cynthia

Born 12-16-54. As of August, 1971, she was healthy with no evidence of endocrine deficiency, pernicious anemia, or superficial moniliasis. In 1964, her serum contained auto-antibodies to gastric mucosa.

Cheryl

Born 4-11-57. As of August, 1971, she was healthy with no evidence of endocrine deficiency pernicious anemia or superficial moniliasis. I 1964 her serum was negative for auto-antibodie against thyroid microsomes, adrenal cortex an gastric mucosa.

Discussion

Idiopathic hypoparathyroidism is an uncommo condition usually manifesting in childhood. It i approximately twice as common in females tha males. Steinberg and Waldron in 1952[2] reviewe 52 cases from the literature including three sibling affected in the family described by Sutphin, et al. Seven of the 52 cases had mucocutaneous monili asis. The cause of idiopathic hypoparathyroidisr is unknown but an auto-immune mechanism i suspected because one-third or more cases hav circulating parathyroid auto-antibodies.[4] This as sumption is further supported by the frequen association of other diseases suspected as bein auto-immune in etiology; namely, Addison's dis ease, pernicious anemia and Hashimoto's thyroid itis. The frequency of auto-antibodies in the ser of patients with idiopathic hypoparathyroidism is[4]: parathyroid tissue 38%, adrenal cortex 11% (normal adrenal function), gastric parietal cell 16% (no overt pernicious anemia) and thyroi microsomes 13% (normal thyroid function). On or more endocrine deficiency diseases may co-exis in the same patient or may alternate in member of the same family.

Mucocutaneous moniliasis occurs commonly i patients with idiopathic hypoparathyroidism an Addison's disease. Blizzard and Gibbs in 1968 reviewed 44 patients (29 females and 15 males over age one year who had mucocutaneous mon iliasis. Thirty-one patients had some associate disease (Table 2). There were five pairs of siblings Only seven of the 31 cases had no antibodie detectable in any tests to endocrine glands o

Table 2
Associated Diseases With Moniliasis

	Female (24)	Male (7)	Total (31
Idiopathic hypoparathyroidism	21	5	26
Idiopathic Addison's disease	9	5	14
Pernicious anemia	7	0	7
Hashimoto's thyroiditis or spontaneous myxedema	2	1	3
Alopecia totalis or universalis	4	2	6
Juvenile cirrhosis	3	0	6
Ovarian failure	3	0	3
Splenic agenesis	1	0	1

stomach. Moniliasis often improved when hypocalcemia was corrected. No evidence was found that moniliasis was either the cause or the result of the associated disease processes.

Pernicious anemia before age 20 with the absence of intrinsic factor has been reported in only 26 patients.[6] These can be subdivided into two groups: (1) 21 cases in which gastric acids and gastric mucosa histology were normal and (2) five cases in which there was a histamine-fast achlorhydria and gastric mucosal atrophy. In the latter group, antibodies to gastric parietal cells or intrinsic factor were detected in the serum of four cases, associated endocrine deficiencies were present and the anemia developed between the ages of 10 to 18 years. The etiology may represent an acquired atrophy of the gastric mucosa such as has been postulated in adults with pernicious anemia.

In contrast, the age of onset in the first group was before two and a half years in the majority. The etiology in this group may be a metabolic error, perhaps a selective biochemical abnormality of gastric parietal cells with failure of intrinsic factor secretion. There were five pairs of affected siblings among the 26 cases. A study of parents of two of these families suggested that the disorder may result from the homozygous inheritance of a gene responsible for the development of pernicious anemia in adult heterozygotes.

The frequency of auto-antibodies in the sera of a large group of patients with pernicious anemia is:[7,8] intrinsic factor (blocking only) 19%, intrinsic factor (blocking and precipitating) 34%, gastric parietal cells (stomach mucosa) 75% and thyroid tissue (cytoplasm) 37%.

Five cases of co-existent idiopathic hypoparathyroidism and pernicious anemia have been reported.[9-13] Three[9,10,13] of the five had no other associated diseases and auto-antibodies were not sought in their sera. In the fourth case, reported by Morse, et. al.,[11] the patient also manifested superficial moniliasis and an incomplete form of cystic fibrosis of the pancreas. Circulating auto-antibodies against intrinsic factor were detected but not against parathyroid tissue. Four of this patient's ten siblings had idiopathic hypoparathyroidism and elevated levels of sweat sodium and chloride, two had Addison's disease and one may have had pernicious anemia.

The onset of pernicious anemia in young patients has always followed the onset of idiopathic hypoparathyroidism by five to ten years. Comin, et al. in 1969[14] reported the first case of pernicious anemia co-existent with idiopathic hypoparathyroidism in an adult woman, age 46. Pernicious anemia was diagnosed at age 40 and idiopathic hypoparathyroidism at age 43, in contradistinction to the order of onset of the two diseases in childhood. The demonstration of circulating auto-antibodies to thyroid microsomes, adrenal cortex and intrinsic factor indicated a similarity between the childhood and adult syndromes.

Familial Addison's disease is also an uncommon entity. In 1959, Meakin, et al.,[15] reviewed the literature and found five reports documented by steroid studies or autopsy findings[16-20] and reported another in two brothers. Since that time, four additional reports fulfilling their criteria have been published.[21-24] The association of idiopathic hypoparathyroidism, superficial moniliasis and Addison's disease is even rarer, only eight patients being reported in the literature.[1,3,25-29] Hung, et al.,[1] and Quinto, et al.,[12] described a family in which Addison's disease was present in three siblings, one of whom also had the first reported combination of idiopathic hypoparathyroidism, superficial moniliasis and pernicious anemia. Auto-antibodies were detected to adrenal cortex and intrinsic factor but not against parietal cells or thyroid microsomes. Their patient developed idiopathic hypoparathyroidism at age four (ours age six), Addison's disease at age eight (ours age 19) and pernicious anemia at age 10 (ours age 11).

The frequent association of Hashimoto's thyroiditis and Addison's disease has long been recognized.[30] A case of triple deficiency of parathyroid, adrenal and thyroid function was presented by Carter, et al., in 1959.[31] In 1964, Kenny and Holliday[32] presented two sisters with idiopathic hypoparathyroidism and superficial moniliasis, one of whom also had Addison's disease and Hashimoto's thyroiditis (thyroid and adrenal antibodies present), a combination previously undocumented, and the other had no other diseases (no thyroid or adrenal antibodies present).

Primary ovarian failure has been described in Addison's disease. Irvine, et al., in 1968[33] carried out a serologic and histologic investigation to determine if antibodies reactive to ovarian constituents were a feature of Addison's disease. Antibodies were found in five of 77 patients with

Addison's disease all of whom had had either a complete failure of menstruation or an early menopause. There was serologic evidence that some cases of premature ovarian failure may have an auto-immune basis.

Summary

The importance of evaluating multiple endocrine function in children or adults with an idiopathic endocrine failure is demonstrated in a family. An important point is that circulating auto-antibodies may signal occult disease which can become manifest at some future time.

Acknowledgments

The authors wish to thank Drs. Stephen D. Mills and Anne S. Goldston, Section of Pediatrics, Mayo Clinic, who studied the mother and four daughters in 1964 and 1966, and Dr. Robert M. Blizzard, Department of Pediatrics, Johns Hopkins Hospital, who performed the antibody studies.

Medical Names and Initials

ARMAND J. QUICK, M.D.

THE EPONYM UNDOUBTEDLY began to be used in medicine long before written records were kept. Numerous parts of the human body had eponymical designations, and many diseases still bear the name of distinguished clinicians. A long list of clinical signs and symptoms are named after investigators who first described or popularized them, and various tests and procedures are known only by the name of the originator.

The eponym still serves as a useful and convenient form of medical shorthand, as illustrated by terms such as Fallot's tetralogy, Benedict's sugar reagent, and Trousseau's sign. Sometimes too it is a means of acknowledging notable achievements cogently illustrated by such terms as the Mendelian laws of heredity, and Pasteurization. As a rule, eponyms are short-lived and rarely a vehicle for conferring lasting fame. A good memory for eponyms is hardly ever evidence of medical erudition, and slavish adherence to outmoded eponyms may block progress.

Initials, likewise, are useful and convenient, but they can result in confusion. P.T. is the commonly accepted abbreviation for the one-stage prothrombin time but the test is not specific for prothrombin, measuring several clotting factors. The abbreviation T.T. in hematology may stand for the thrombin time, thromboplastin time, thrombo test, or the tourniquet test. Such initials may become very confusing.

When initials are based on uncertain or inaccurate terms, misinterpretations of even such well known expressions as I.T.P. may occur. While I.T.P. is tacitly accepted to mean idiopathic thrombocytopenic purpura, it is doubtful whether idiopathic, which means of unknown origin, is always correct since the cause may be known. Much greater clarity could often be achieved if the meaning of "I" were changed from idiopathic to immune.

Eponymization in Hematology

Eponymization in the bleeding states began after Werlhof gave the imposing name of morbus maculosis haemorrhagicus to purpura, a term soon replaced by Werlhof's disease. Nearly a century later, Schönlein recognized another type of purpura which he called peliosis rheumatica because it was accompanied by joint symptoms. Soon, it was given the name of Schönlein's purpura and when Henoch described a purpura associated with gastrointestinal bleeding, it too, soon bore his name and, when it was later found that the two types of purpura were different manifestations of the same disease, the names of Schönlein and Henoch were linked. When it was found that the platelet count in Werlhof's purpura was reduced, while it was normal in number in the Schönlein-Henoch purpura, the differential diagnosis of the two types was established. Though much of the work resulted from the creative contributions of the French hematologist Hayem, he is now known to many hematologists only because his name is attached to the useful reagent—Hayem's solution.

Von Willebrand's Disease

The disease now commonly designated as von Willebrand's disease probably represents hematological nomenclature at its worst. The blame for this can be found in the irregular manner with which most medical knowledge has developed. As already pointed out, Werlhof's purpura was the first and the only clearly designated bleeding disease. In 1802 Otto described "a hemorrhagic disposition" with a characteristic hereditary pat-

This work was supported by a grant from the National Heart and Lung Institute, National Institutes of Health, U.S. Public Health Service.

tern which led to the establishment of the condition as a distinct disease which 24 years later assumed the permanent name of hemophilia. In this entity, the clotting time was found to be prolonged. Thus, it was the first bleeding disease in which a laboratory test became useful for diagnosis. At the beginning of this century, only two bleeding states were generally recognized—purpura and hemophilia—and the common laboratory test was the clotting time which was crude and unstandardized. Gradually, this void was filled by the bleeding time of Duke in 1910, more careful standardization of the clotting time by Lee and White in 1913, and the introduction of the tourniquet test into America by Hess in 1914.

It was these three tests that substantiated the statement Hess made in 1916: "It is becoming increasingly evident that the group termed 'hemorrhagic diseases' includes a large number of abnormal conditions and that at the present time it is a fruitless task to attempt to unravel the various entities . . ." It was Minot and Lee, who, in 1920, began the unravelling of these states when they reported a family with familial recurrent epistaxes and a prolonged bleeding time but a normal clotting time and platelet count. Minot was aware that epistaxis was just one finding in this systemtic disorder which, in 1928, he described succinctly: "There exists a chronic familial hemorrhagic condition characterized by a prolonged bleeding time in the absence of a decrease of blood platelets and a delayed coagulation time of the blood. Multiple ecchymoses and recurrent epistaxis are characteristic symptoms. Pathologic blood loss and abnormal bleeding may be present at one time and not at another, but their occurrence is not necessarily synchronous. This hemorrhagic condition appears in infancy and may extend into adult life, but then its severity tends to decrease and the condition may disappear as the patient grows older."

Minot did not give the disease a specific name. During this period, von Willebrand studied a family with a similar bleeding state living on the Åland Islands in the Baltic Sea. His first report in 1926 was in a Finnish medical journal and it was therefore not until 1931 when he reported in German that his findings became readily available. In his patients it too was the prolonged bleeding time that was the outstanding feature of the disorder. Von Willebrand called the disease hereditary pseudohemophilia but after he and Jürgens (R.) presented what they considered as evidence of defective platelets, the condition in the European medical literature began to be commonly called the von Willebrand-Jürgens constitutional thrombopathy and this has now been simplified to von Willebrand's disease.

Rendu-Osler Disease

The clinical condition reported by Rendu in 1896 in which he observed hereditary recurrent epistaxes with characteristic skin and mucous membrane lesions has been an especially eponymophilic disease entity. Osler's name supplied valuable prestige but to it have been added the names of Sutton, Parkes-Weber, Goldstein, and others. Hanes offered the valuable suggestion that the disorder be named hereditary hemorrhagic telangiectasia. This helped to simplify the nomenclature and also to characterize better the nature of the disease, which none of the eponyms had done. What is apt to be overlooked is that telangiectasia is a purpura and that bleeding is not merely from the more spectacular telangiectatic lesions but also from those of minor importance. In many patients with the trait, both the tourniquet test and the bleeding time are abnormal, though the platelets are normal in number and quality.

Glanzmann's Purpura

In 1918 Glanzmann described a new hereditary diathesis appearing in both sexes in which bleeding was of the purpuric type—oozing from mucous membrane, and hemorrhaging into the skin. The bleeding time, the clotting time and the platelet count were normal but clot retraction was delayed or absent. Such a combination of laboratory findings has never since been reported, but I have had the opportunity to study a purpuric state simulating in many aspects, the findings of Glanzmann. The patient has a severe purpuric condition at birth and, for over two years, she completely lacked clot retraction despite a normal platelet count. She has, however, a very long bleeding time and a very poor prothrombin consumption. Clot retraction is gradually improving but not the bleeding time nor the prothrombin consumption time.

At the time that Glanzmann reported his cases, precise and highly standardized tests for platelet function were not available but, despite this han-

icap, he made the important contribution by mphasizing that the role of platelets in hemostasis epends not only on their number but also on heir quality. His term "thrombasthenia" is still alid and his speculation that clot retraction was ue to an enzyme, retractozyme, while not strictly orrect, was the forerunner of the retractile pro- ein thrombosthenin.

Just as von Willebrand's disease is basically haracterized by a prolonged bleeding time, so Glanzmann's disease has as its key defect, faulty lot retraction. But defective clot retraction, ex- ept in acquired thrombocytopenic purpura, is xceedingly rare. Far more important in heredi- ary platelet dysfunction is the lack of a specific latelet clotting factor which is usually designated s platelet factor 3 (PF_3). The clotting factor in latelets is readily diagnosed and quantitatively neasured by the prothrombin consumption test.

Hereditary Non-Thrombocytopenic Purpura

These hereditary states chiefly known by their eponymic designation can be grouped under the general term of hereditary non-thrombocytopenic purpura. In all, the clotting time is normal and the platelets are, at the most, only moderately reduced. All have in common that the bleeding time may be entirely normal but often prolonged and, in many instances, significantly. Likewise, the tourniquet test shows the same variations. The prothrombin time is normal or only slightly prolonged while the prothrombin consumption test may also be normal. When abnormal, the latter test becomes a critical factor in the differential diagnosis. Inconsistencies in platelet adherence and aggregation have also been recorded.

The condition is essentially purpuric. Epistaxis is the most common form of bleeding, especially in childhood, and easy bruising is almost equally as common. Menorrhagia is frequent but menses may be entirely normal. Gastrointestinal bleeding, while usually infrequent and mild in youth, may be most troublesome and alarming in old age. Paradoxically, a minor surgical operation such as a tonsillectomy or tooth extraction may give rise to serious bleeding, whereas the same patient may undergo a major abdominal operation with impunity. Traumatic bleeding seen in hemophilia, such as hemarthrosis, deep intramuscular bleeding and hematuria, is conspicuous by its absence. This clinical state has befuddled the physician to whom such patients first turn for help.

In attempting to understand the state of the hereditary, nonthrombocytopenic purpuras, it must be recognized that the eponyms have outlived their usefulness. For instance, the Rendu-Osler disease as a distinct clinical entity is probably very rare. It is a common hereditary trait that only gives clinical manifestations when associated with another hemostatic defect and subjected to provocative agents of which aspirin and, perhaps, alcohol are the most common. Most of the states designated as Glanzmann's disease are thrombopathies in which thrombasthenia (lack of clot retraction) is a subordinated facet of platelet dysfunction. Von Willebrand's disease is a conglomerate of inherited defects, many of which would have remained dormant had it not been for the introduction of aspirin into therapy. This drug not only called attention to the defect by prolonging the bleeding time but also by accentuating the bleeding tendency.

It is certain that in a segregated population such as that of the Åland Islands, a trait such as telangiectasia, which is transmitted as an autosomal dominant, is likely to be as common as the still undefined von Willebrand trait. Then, too, the aspirin intolerance as measured by the aspirin tolerance test appears to be transmitted as an autosomal dominant. This is also true of one type of hereditary thrombopathy which is diagnosable by the prothrombin consumption test.

Telangiectasia is now known to exist in one family of the Åland pedigrees,[1] and also in an Icelandic family reported as von Willebrand's disease.[2] Edson[3] has seen one case in which telangiectasia co-exists in a patient whom he had diagnosed as von Willebrand's disease.

Numerous cases formerly diagnosed as von Willebrand's disease have later proved to be combinations of telangiectasia and aspirin intolerance, telangiectasia and hereditary thrombopathy, and other combinations of mild hemostatic defects. The pitfalls in diagnosis have been that: (1) basic laboratory tests such as the bleeding time, and the tourniquet test, the prothrombin consumption time are often not carried out nor interpreted properly. (2) the patient's history is often incomplete and the importance of spontaneous epistaxis in childhood overlooked, and (3) the telangiectatic lesions are missed.

Rather than cling to eponyms that have out-

lived their usefulness, names such as Rendu, Osler, Glanzmann, Minot, von Willebrand can be consigned to the history of medicine and the purpuric bleeding states redesignated on the basis of more exact diagnostic criteria. Telangiectasia is perhaps the most specific to diagnose. In the adult the lesions are most common on the back, arms, chest and face but are often absent in mucous membranes. In many patients, the tourniquet test is usually strongly positive. In children the typical lesions may not be present but only appear later in life.

All purpuric cases should have in addition to an accurate medical history and a physical examination, standardized bleeding, tourniquet, prothrombin, prothrombin consumption, and aspirin tolerance tests performed. It should also be borne in mind that most patients with purpuric bleeding have dual or multiple defects.

Disseminated Intravascular Clotting (DIC)

Intravascular clotting has been recognized since the time of Harvey and it is difficult to state exactly what "D" in the combination of DIC really means. DIC, furthermore, has been closely associated with another pathological process—consumption-coagulopathy. In 1935 my associates and I[4] carried out what was perhaps the first experimental consumption-coagulopathy. We described it as follows: "A freshly prepared and filtered saline extract of rabbit brain (20 cc.) was injected intravenously into a dog. A severe reaction occurred immediately, respirations became shallow, and a nystagmus developed. The fibrinogen which was 0.44% before the injection dropped to 0.09 in five minutes and to a mere trace 30 minutes after the injection. The dog was killed one hour later and autopsied. No definite intravascular clotting could be found, but there was a relatively small pulmonary infarct and also a small mesenteric infarct."

The first clinical report of consumption-coagulopathy was made in 1936 when Dieckmann[5] associated the obstetrical bleeding state characterized by lack of fibrinogen in the blood with premature separation of the placenta. It is now well established that both premature separation of the placenta and uterine retention of a dead fetus result in bleeding and that in this state several clotting factors in the blood are significantly diminished. Another condition in which a similar type of consumption-coagulopathy occurs is cavernous hemangiomas. In both the obstetrical states and in giant hemangioma a continuous escape of either preformed thromboplastin or thrombin into the bloodstream takes place at such a slow rate that massive thrombosis does not occur but the fibrils of fibrin and platelet aggregates are continuously filtered off in the capillary network. Such a process can also be produced by injecting a dilute solution of thrombin at a very slow steady rate directly into the bloodstream.[6] Under these circumstances, no massive thrombosis is produced but the circulating fibrinogen is slowly changed to fibrin and removed from the bloodstream. The platelets decrease in number and in quality. The prothrombin time becomes prolonged mainly because of a decrease of factor V and the prothrombin consumption time shortened because the consumption of prothrombin is blocked, first, by platelets reduced both in number and quality and, also, by decreased factor VIII. Eventually, fibrinolysin activity also becomes a dominant feature since profibrinolysin or plasminogen becomes activated and escapes into the bloodstream.

In such clinical or experimental states the complete picture of consumption-coagulopathy is produced. The disappearance of fibrinogen and the marked drop in the platelet count are easiest to detect but the diminution of factor V and VIII are equally striking. Prothrombin is reduced less and factors VII, IX and X are little affected. Crucial is the resulting lack of the platelet-containing factor usually called platelet factor 3. The states discussed are genuine intravascular clotting, not disseminated, since the source of the clotting agent, be it tissue thromboplastin or thrombin, is localized.

Many of the current papers dealing with DIC correspond to what was formerly designated I.T.P. Perhaps, the most common form of consumption coagulopathy is I.T.P. with its new meaning of "immune" thrombocytopenia. The fall in the platelet count may be gradual or precipitous but the replaced platelets are deficient in the clotting factor which is sensitively measured by the prothrombin consumption time test. Apparently, in the immune process, the platelets are aggregated and removed rapidly by filtration in the capillary beds. Too little reduction of the other clotting factors occurs to be measurable. DIC is therefore

not an accurate designation. According to the initial-system, DPA (disseminated platelet aggregation) would more closely describe the immune reaction.

No justification can be found for adopting DIC as an all-inclusive term. The extensive consumption-coagulopathy which is so prominent in placenta abruptio or giant hemangioma is entirely different from the various immune reactions grouped under the initialled designation. Both the basic etiology and the management are completely different. In some, heparin is the effective therapeutic agent and, in others, the corticosteroids. Sometimes, a fibrinolysin blocking agent such as epsilon-aminocaproic acid seems indicated. To base therapy on a blanket diagnosis of DIC can be disastrous.

Tuberculosis

I had not seen him for ten days, and was appalled by the fearful alteration which the brief interval had wrought in him. His face wore a leaden hue; the eyes were utterly lustreless; and the emaciation was so extreme, that the skin had been broken through by the cheekbones. His expectoration was excessive. The pulse was barely perceptible. He retained, nevertheless, in a very remarkable manner, both his mental power and certain degree of physical strength. He spoke with distinctness—took some palliative medicines without aid—and, when I entered the room, was occupied in pencilling memoranda in a pocketbook. He was propped up in the bed by pillows. Doctors D..... and F..... were in attendance.

After pressing Valdemar's hand, I took these gentlemen aside, and obtained from them a minute account of the patient's condition. The left lung had been for eighteen months in a semi-osseous or cartilaginous state, and was, of course, entirely useless for all purposes of vitality. The right, in its upper portion, was also partially, if not thoroughly, ossified, while the lower region was merely a mass of purulent tubercles, running one into another. Several extensive perforations existed; and, at one point, permanent adhesion to the ribs had taken place . . . It was the opinion of both physicians that M. Valdemar would die about midnight on the morrow.*

Historic Hospitals

The Nuri Hospital, Damascus

Entrance to the Nuri Hospital. Damascus, Syria. Courtesy of the Smithsonian Institution, Freer Gallery of Art, Washington, D.C.

The most advanced hospitals of the medieval period were the Arab hospitals of the Eastern Caliphate. Outstanding among them was the Nuri Hospital at Damascus, pictured here. The hospital was founded by Sultan Nur al-Din Zengi in 1154 and its construction financed by the ransom collected for the release of a European king captured in the Crusades. The building surrounded a rectangular court with a pool in the center. Four open rooms on the main axis served as the consulting rooms of the physicians, while six other rooms provided wards for the patients. An annex was added in 1239, and running water installed in its various departments at that time.

The daily routine of the chief physician included daily hospital rounds, accompanied by his assistants and orderlies, examining patients and giving orders for their medication and care. After rounds he read and prepared lectures in the hospital library. For three hours each afternoon he sat with his physicians and students, teaching, discussing medical topics, and considering the difficult cases.

The hospital had a rich income for the time, provided by the sultan. Typical of the medieval Arab hospitals, there was no charge to the patients for their care. The food was said to be so good that malingerers occasionally entered just to partake of the hospitality.

Considerable prestige went with appointment to the medical staff of this institution which functioned as a public hospital for about seven centuries. The most distinguished advancement credited to the hospital, however, is not a strictly medical one, but pertains to the keeping of medical records. The register of patients kept by the administrator is probably the first of its kind in the history of hospitals. Beside each name the physician making his daily rounds recorded the orders for the day. This simple register was a prototype of the untold millions of hospital charts which today occupy complex medical records departments, some of which are larger than the entire Nuri Hospital.

Intramuscular Neurolysis for Stroke

ESSAM A. AWAD, M.D., Ph. D.

It is estimated that half a million Americans suffer from cerebral vascular attacks each year, and that there are two million persons alive in the United States who have neurologic manifestations of stroke. This problem is also expected to become more prevalent because of the increase in longevity. Most of the stroke patients demonstrate varying degrees of functional impairment. Disability ranges from total incontinent dependency to almost complete self-sufficiency with residual difficulties in the use of the upper and lower extremities involved.

This communication concerns itself with a method proved helpful in restoration of useful function in the hemiplegic hand and in improving ambulation of the stroke victims.

Statement of the Problem

It is a widely known fact that the hemiplegic extremities manifest flexor spasticity, following the initial flaccid phase. This flexor spasticity and the associated paresis maintain the shoulder adducted and internally rotated, the elbow flexed, the forearm pronated, and the fingers and the wrist flexed. In the lower extremity, the hip and the knee are flexed and the ankle is plantar flexed. Spasticity involving the hand and the upper extremity often renders the hand useless for the patient. Spasticity of the plantar flexors of the foot interferes with the ability of the patient to walk; sometimes an ankle clonus develops whenever the gastrocnemius-soleus complex is stretched as the patient's forefoot touches the floor. In addition, the patient's heel tends to slip out of his shoe because of the spasticity and plantar flexion. The problem then is: (a) inability of the patient to grasp objects because of flexor spasticity of the finger and wrist muscles, (b) difficulty in ambulation due to spasticity and ankle clonus in the lower extremity.

Attempts to overcome spasticity through the use of drugs are far from satisfactory; many patients become drowsy and the spasticity is never completely abolished while the patient is fully conscious. Surgical procedures such as tenotomy or neuroectomy have been used. The technique to be described taxes the patient less heavily than any surgical procedure. In addition, it has the advantage of tailoring the degree of neurolysis to the individual muscle so that one can retain proper function and at the same time abolish undesirable spasticity.

Technique

Intramuscular neurolysis is a simple technique for control of spasticity in the stroke patient. This method applies to any skeletal muscle.[1] The following three steps are followed:

1. Localization of the motor point: This point is defined as the most irritable point of a given muscle, or the point on the skin at which an electrical stimulus of minimal amplitude and duration will result in a visible contraction of that muscle. The motor points of superficial muscles are easily defined. Motor point charts are available and serve as a good guide for the beginner.[2] Some muscles such as the gastrocnemius which have two heads, also have two motor points. The physiatrist, as well as the physical therapist, are both capable of performing this step. An electrical stimulator known as a "chronaximeter" is used for this purpose.

2. Insertion of needle electrode at the motor point and localization of the motor innervation band: An injection needle coated with an insulating substance except for its tip and connected to the output of the chronaximeter is inserted into the muscle at the motor point. The stimulus intensity is reduced to approximately one milliampere and its duration to 1/10th of a millisecond. This stimulus is repeated automatically at a rate of one or two per second. When the needle tip is in close contact with the motor

This study was supported in part by Social Rehabilitation Service Grant RT-2.

See editorial, page 742.

nerve fibers, fascicles of the muscles will contract and relax rhythmically at the same rate as the electrical stimulus.

3. Phenol Injection: the injection of a trace (usually 0.1 c.c) of 5 percent phenol solution in water at this time will be followed by cessation of the contractions despite continued stimulation. The immediate effect of phenol makes it easy for the physician to determine the results instantaneously and to evaluate the patient's need for further blocks in the same muscle. The injection of one site results in denervation of only one fascicle in the muscle. If the spasticity is severe, one might have to block several points in one muscle until the desired effect is achieved, e.g., abolition of a clonus.

Results

Sixty-two intramuscular neurolysis procedures were performed on forty-one stroke patients. All patients were referred to us for control of hypertonus which interfered with hand function or with ambulation. Some patients underwent neurolysis of more than one muscle group during the first visit, e.g. plantar flexors of the foot and wrist and/or finger flexors. Several patients returned for a second and occasionally a third block. The duration of the effectiveness of a procedure was four to 14 months. It is extremely difficult to determine the duration of the effects because recurrence of spasticity is very gradual and takes place over a period of several weeks or months.

Twenty-nine patients underwent intramuscular neurolysis of the plantar flexor muscles of the foot in order to eliminate spasticity and clonus which caused shuffling of the forefoot during walking and apparent lengthening of the paretic lower extremity with resultant flexion at the knee and hip and circumduction of the leg.. These patients, also, had a tendency to trip over their foot during ambulation on a carpeted floor. Many were unable to keep their heels inside their shoes. Following this procedure the involuntary activity and ankle clonus were abolished in all cases leading to improvement of ambulation.

Twenty-two patients underwent intramuscular neurolysis of the wrist and/or the finger flexors of the paretic upper extremity. Prior to this procedure, the hand and wrist were held in severe flexor spasm (Figure 1). In three females, the neurolysis was performed in order to enable them to wear gloves or mittens during the winter. Ten patients were able to flex and extend the fingers of the paretic hand to the extent that they were able to hold the telephone receiver (Figure 2). This allowed them to use their other hand for writing. This is an important achievement in the vocational rehabilitation of the stroke victim. Twelve patients had good control of spasticity, but were unable to grasp objects with their paretic hand because of lack of finger extensor strength.

In five patients, intramuscular neurolysis was performed on the hip adductors of the paretic side. This was done at the same time the plantar flexors were blocked to control severe adduction of the lower extremity in order to improve the gait pattern.

Partial neurolysis of the hamstring muscles in five patients and of the quadriceps femoris in one patient was carried out to control spasticity and improve gait.

Fig. 1—Left hand of a patient who had a stroke for over two years, showing maximal voluntary extension prior to intramuscular neurolysis.

Fig. 2—Immediately following neurolysis of the finger flexors. the patient is now able to extend her fingers and to grasp objects.

Discussion

Intramuscular neurolysis is a process of chemical partial denervation. Reinnervation is to be anticipated with recurrence of hypertonicity. However, the relief lasts four to 14 months, depending on such factors as: (a) the extent of neurolysis performed; (b) the amount of phenol used; (c) the presence or absence of other factors which aggravate spasticity, such as urinary tract infections or skin ulcers; (d) recurrence of cerebrovascular accidents.

Because phenol solution results in aseptic coagulation necrosis of very small areas in the muscle, it leads to a certain amount of fibrosis, which seems beneficial as it interferes with the regeneration of the distal segment of the intramuscular nerve fibers. The cumulative effect of this incomplete reinnervation—following repetition of neurolysis—resulted in a permanent effect. In some patients there *was no* need for further neurolysis after repeating the procedure three or four times.

Phenol has passed the test of time and is accepted as a local blocking agent. It is free of local irritation and systemic toxicity, easily sterilized and available at low cost.

Since spasticity is a state of abnormally excessive involuntary contraction, due to increased activity of the myotatic reflex, it seems reasonable to control it by means of interruption of the pathway of this reflex. This is the effect of phenol on the intramuscular nerves.

Conclusion

Intramuscular neurolysis of spastic muscles is an excellent method to control hypertonicity in the stroke patient. In all cases, plantar flexors spasticity could be reduced and ankle clonus abolished. This enables the patient to walk with a better gait. In some cases, hand function could be substantially improved, to allow the patients to grasp objects and to wear gloves or mittens during the winter.

"Mississippi Idyll"

Dr. Farrell Stiegler, Cover Editor of MINNESOTA MEDICINE, took this photo of the Medical School (Mayo Memorial) and the Showboat in January of 1971. He used a Linhoff 2¼ x 3¼ Camera with a 100 mm lens and Ektachrome Film.

Dr. Stiegler is a surgeon practicing in Minneapolis, and states that his reason for selecting this particular cover is to stimulate other physicians to submit more pictures of Minnesota to the Cover Editor of MINNESOTA MEDICINE.

A man doesn't live by bread alone. He needs buttering up once in a while.

Distinguished Teaching Award

(L-R) John W. Frost, M.D., chief of medicine at St. Paul-Ramsey and president of the Minnesota Medical Foundation; Wesley D. Anderson, D.V.M., Ph.D., recipient of the 1972 Distinguished Teaching Award jointly sponsored by the Minnesota State Medical Association and the Foundation, and George B. Martin, M.D., Thief River Falls, president of the State Association.

Wesley D. Anderson in the Anatomy Department has been chosen by medical students of the University of Minnesota to receive the 1972 Distinguished Teaching Award of the Minnesota State Medical Association and Minnesota Medical Foundation. The award of $1,000 is contributed by the Minnesota State Medical Association.

The 47-year-old associate professor of human anatomy was chosen for this honor by medical student poll. The award recognizes excellence in teaching medical students and also notes demonstrated concern for their welfare. Dr. Anderson is the 19th recipient in 11 years of the award program.

The award was presented in May by Dr. John W. Frost, president of the Minnesota Medical Foundation and Dr. George B. Martin, Thief River Falls, president of the Minnesota State Medical Association, co-sponsors.

Dr. Anderson received his D.V.M. degree from the University's School of Veterinary Medicine in 1951 and operated a veterinary practice in Rosemount, Minnesota, for 10 years. He left his practice in 1964 to join the faculty of the veterinary school. He also continued his graduate studies at the University Medical School and at the Mayo Graduate School in Rochester and received a Ph.D. in human anatomy in 1969. He joined the faculty of the Medical School shortly thereafter.

Dr. Anderson has engaged in many research projects, most of them dealing with tensile strength and blood flow in arterial systems of man and other animals.

Single, Combined and Sequential Use of Uracil Mustard and Prednisone

in the Treatment of Lymphoreticular Tumors

I. E. FORTUNY, M.D., A. THEOLOGIDES, M.D., Ph.D., and B. J. KENNEDY, M.D.

PREDNISONE OR URACIL MUSTARD used alone have been shown to be effective agents in the management of Hodgkin's disease, other lymphomas and chronic lympathtic leukemia.[1-13] During the early investigation of these agents, it was noted that certain patients with lymphoma, failing to respond to uracil mustard or prednisone alone, did demonstrate a response when these agents were administered concomitantly.[5,6,12] We, then undertook an investigation to compare the effectiveness of uracil mustard and prednisone, administered individually, sequentially, or in combination.

Patients and Methods

Sixty-three patients with the following disease were treated: Hodgkin's disease, 19; poorly differentiated histiocytic lymphoma (reticulum cell sarcoma), eight, other lymphomas (well differentiated and poorly differentiated lymphocytic lymphomas), 36. All the patients were in advanced, disseminated stages of their disease (Stages III and IV). Thirty-one of the patients had received radiation therapy previously, and upon reactivation of their disease, were included in the study (Group A); the remaining 32 patients had no treatment prior to entering the study (Group B).

Patients were randomly assigned (Table 1) to one of three drug schedules: uracil mustard alone, prednisone alone, or a combination of both. Uracil mustard was administered orally at a dose of 10 mg daily for three days. Prednisone was given in a daily oral dose of 40 mg for thirty days. The same drug doses and routes of administration were used for the combination schedule. Response to treatment was evaluated at four week intervals. When complete objective response was obtained, the drug cycle was repeated at six to eight week intervals for as long as the response could be maintained. Patients showing a partial response or failing to respond at the end of two or three evaluation periods after treatment with one of the drugs were placed on the other drug, and the response was evaluated at similar intervals.

Criteria for objective response were based on measurable changes of enlarged lymph nodes and tumor masses or healing of skin lesions. Disappearance of tumor masses or lymph nodes and healing of skin lesions constituted a complete response. Noticeable improvement of lesions, but without complete disappearance, was considered a partial response. Progression, or no measurable change in the observed lesions, was designated as a failure to respond.

Results

On the drug combination schedule 76.2% of the patients had an objective response, complete or partial, compared to 64.2% of patients responding to prednisone alone, and 60% to uracil mustard alone (Table 2). The differences are not

statistically significant. The quality of tumor response was comparable in the three drug schedules (Table 2), although a more rapid response was observed in patients receiving the drug combination. There was no difference in the rate of response between the patients who had received irradiation previously (Group A) and the patients who had no treatment prior to entering the study (Group B).

The median duration of response for patients showing complete objective remission [and maintained subsequently by repeated courses every six to eight weeks] was 16 months for both the uracil mustard and the combination therapy group. In the prednisone only treated group the median remission was approximately of three months' duration. Once a remission was attained, maintenance was achieved by re-induction every six to eight weeks.

The breakdown in the response rate following the sequential drug regimen is shown in Table 3. Of the nonresponders and partial responders to the first drug, 50% responded partially or completely to the second drug. Of the patients who received uracil mustard as the second drug, two had complete remission of six and 10 months' duration respectively. Of those who received prednisone as the second drug, three had complete remission of two, three, and four months' duration. All these five patients were partial responders to the first drug; and none of the nonresponders to the first drug responded completely to the second drug.

TABLE 3
Response of Lymphoreticular Tumors to Sequential Drug Therapy

Initial Treatment			Response to the other drug (partial or complete)
Uracil Mustard	No response	10	3
	Partial response	8	6
Prednisone	No response	6	2
	Partial response	6	4

Discussion

The present study shows that in Hodgkin's disease, and lymphomas, uracil mustard and prednisone used alone can induce partial or complete remission in about 60% of the patients. In contrast to previous suggestions[5,6,12] the combination of these two drugs did not improve significantly the rate of response but probably induced a more rapid response than either of the two drugs used alone. This effect can be advantageous for a rapid regression of the tumor when the lymphomatous masses cause serious complications.

When a complete response was obtained by uracil mustard or the combination of the two drugs, the median duration of the control of the disease with repeated similar courses was by far greater than the median control with prednisone alone. A patient failing to respond to one of these two drugs has limited chances of responding subsequently to the other drug used alone.

Summary

In advanced Hodgkin's disease and lymphomas, prednisone and uracil mustard used alone produced similar rates of regression as their use in combination. With the combination, the induction of remission appeared to be more rapid. Patients who failed to respond to either drug alone had limited chances of responding to the other drug used subsequently.

Concurrent Conditions and Diseases in Injured Persons

DONALD K. WHEELER, M.D. and EDWARD D. HENDERSON, M.D.

A SERIOUSLY INJURED person may have a concurrent disease that is undiagnosed or ignored because of the need for immediate treatment of the injury. Concurrent disease in an injured person frequently results in longer hospitalization and increased morbidity; it may even result in the death of the patient. Because this subject is frequently forgotten in practice and in the literature, this study was undertaken.

Method

In 1962 and 1963, there were 49,757 patient visits to the emergency room of St. Mary's Hospital in Rochester, Minnesota. Of these, 14,620 involved injured persons and 1,166 of them required hospitalization. Of these 1,166 admissions, 1,144 case records were reviewed; the remainder were incomplete or unavailable.

Injured patients were evaluated as to age, sex, residence, date and place of accident, cause of injury, nature of injury sustained, days of hospitalization, surgical procedures, known prior diseases, disease or condition contributing to the cause of the accident, concurrent disease that prevented surgical treatment of traumatic conditions, emergency surgical procedures performed for concurrent disease, deaths and causes of death.

Dr. Wheeler is a Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.
Dr. Henderson is from the Section of Orthopedic Surgery, Mayo Clinic and Mayo Foundation.

Analysis of Patients Hospitalized for Injury

Cause of Injury

In 1,144 patients there were 1,358 injuries, falls and car accidents being the most common causes of injury (Table 1). The relatively large number of farm accidents and injuries sustained while riding horses is related to the rural location of the hospital. Of the 470 patients who had falls, 51% were more than 50 years old; 28% of the patients injured by a fall were between the ages of zero and nine years. Fifty-one percent of the 302 patients injured in car accidents were between the ages of 10 and 29 years; 58% of burn victims and 78% of the persons struck by automobiles were between zero and 20 years old. Most athletic injuries, bicycle accidents, motorcycle accidents, and injuries sustained riding horses happened to persons less than 30 years old. The age distribution of farm accidents remained constant until 60 years of age.

Types of Injuries

The types of injuries at various ages are shown in Table 2.

Head injuries, comprising 27% of the total number of injuries, were subdivided into serious and minor injuries. If he had been admitted for observation for a few days but required no surgical or angiographic studies, the patient was classified as having sustained a minor head injury.

TABLE 1
Causes of Injuries According to Age Groups

TABLE 2
Type of Injuries According to Age Groups

Type of injury	Age, year 0-9	10-19	20-29	30-39	40-49	50-59	60-69	70-79	80-89	90-99	Total
Total	257	305	188	81	114	110	104	123	62	14	1,358
Fractures	81	128	68	36	53	69	61	82	51	14	643
Head injury	119	90	44	21	24	21	21	15	5	0	360
Internal injury	3	13	8	2	5	2	4	3	0	0	40
Burn	15	7	2	2	4	2	0	5	0	0	37
Eye injury	1	4	1	0	1	1	0	0	0	0	8
Soft tissue injury	33	56	60	19	24	12	16	18	6	0	244
Miscellaneous	5	7	5	1	3	3	2	0	0	0	26

In this series, there were 135 serious injuries and 225 minor injuries; 31% of the serious head injuries required emergency surgical treatment. More than half of the head injuries occurred in patients less than 20 years old.

Most of the internal injuries were sustained in serious car accidents and farm accidents.

The majority of burns and injuries of the eye occurred in patients under 20 years old.

Fractures (excluding skull fractures) comprised 47% of the total number of injuries; the distribution according to body location is shown in Figure 1. The majority of fractures occurred in the extremities and were more common in the upper extremity than in the lower extremity, excluding hip fractures. The majority of upper extremity fractures were forearm fractures in young patients; the majority of the 106 hip fractures occurred in women over the age of 60 years. Emergency open reduction was required in 89 of the 643 fractures, and 155 nonemergency operative procedures were done. Some patients had several operations and several patients had multiple fractures; therefore the exact number of patients requiring open reduction of fractures was not determined.

Age and Sex Distributions of Injured Patients

In this series of 1,144 injured persons, 62% were males and 38% females (Table 3). There were more males than females among the patients 60 years old or younger; among those over 60, there were more females. Forty-three percent of the patients were between the ages of zero and 20 years.

Length of Hospitalization

The average duration of hospitalization was 11.6 days. It was least (average, five days) in the age group up to nine years and greatest (average, 23 days) among those over age 90. Among those more than 70 years old the average hospitalization was over 20 days.

Residency of the Patients

Of the 1,144 injured persons, 359 were from this city, and they came directly to the hospital. 597 were from surrounding areas in the State of Minnesota and, of these, 48% came directly to the hospital and 52% were referred by other physicians. The majority of those who came directly to the hospital were from nearby towns. 188 came from surrounding states (96% were referred patients and only 4% came directly to the hospital). The majority of patients who were referred by another physician were severely injured and needed extensive care.

Analysis of Concurrent Conditions and Diseases

Table 4 shows that in the 1,144 injured persons there was an overall incidence of concurrent conditions and diseases of 22%. The 10-to-19-year age group had the lowest incidence (4%) and the 90-to-99-year age group had the highest (85%). In general, the incidence of concurrent conditions or diseases increased with increasing age.

Total	1,144	252	22.0	60	5.2

Distribution of Concurrent Conditions

Table 5 shows the distribution of the 349 concurrent conditions and diseases. The most common was the cardiovascular group (32%), most of whom were more than 60 years old. The most common metabolic disease was diabetes mellitus. The most common diseases among patients in the first decade of life were neurologic diseases and respiratory infections.

Acute alcoholism accounted for 75% of the concurrent conditions among those between the ages of 20 and 29 years.

Table 4 also shows that in 60 patients (5.2% of the total number injured) the concurrent disease or condition directly contributed to the cause of the trauma, and acute alcoholism was the most common of these (42 instances). Other concurrent conditions or diseases that contributed to the cause of the trauma were Parkinson's disease (four), vertigo (two), syncope (five), blindness (two), depression (two), grand mal seizure (one), and convulsion (one). These latter diseases and conditions were most commonly found in the older age groups.

Conditions Requiring Treatment

Of the 1,144 patients hospitalized for trauma, 107 had concurrent diseases or conditions that required further medical evaluation and treatment.* Emergency surgical procedures were delayed in 11 patients until the medical problem was attended to; the most common causes of delay were acute alcoholism, diabetes mellitus, and anemia.

Disease First Discovered

In 87 cases, the condition or disease was first discovered at the admission examination or during hospitalization for the accidental injury (Table 6). The two most common diseases found were cardiovascular disease and diabetes mellitus. The majority of these patients were elderly persons who had not visited a physician for several years prior to the accident.

Patients Requiring Concurrent Surgery

In two patients (66 and 88 years old), subtotal gastrectomy was done for perforated duodenal ulcers on the third and fourth days after surgical treatment for their injuries; both recovered and were dismissed after 18 and 39 days, respectively. A third patient had a perforated gastric ulcer on

Four patients had concurrent disease too severe to permit surgical treatment of their injuries (Table 7). All were elderly patients with fractured hips, and none lived more than six days after admission.

Deaths

There were 53 hospital deaths (36 among males and 17 among females), an overall mortality of 4.6%. Figure 2 shows that the age distribution of deaths closely paralleled that of injuries up to age 50 years, after which the death rate increased sharply.

Thirteen of the 53 deaths occurred within 24 hours after admission; the leading cause was severe head injury. Twenty-three patients died from their initial injury, most of them within 72 hours after admission. Thirty patients died from postoperative complications such as pulmonary embolus, bronchopneumonia, cerebrovascular accident, or concurrent diseases.

There were no deaths during surgical procedures, but three patients died during intubation for anesthesia prior to a surgical procedure; their average age was 74 years.

Discussion

The current philosophy of management c trauma is based mainly on military experienc acquired in two recent wars, but this experienc is limited in that, for the most part, it involve young men in good general health except for thei wounds. Such patients are the exception rathe than the rule in ordinary peacetime practic Life spans are longer, and hospital admissions c patients over 60 years are gradually increasin For example, between 1949 and 1959, admission for treatment of fractures in patients over 6 years increased from 39 to 54% at the Peter Ben Brigham Hospital.[1]

The yearly increase in the number of injurie and deaths in the home and on the highway i verified by the National Safety Council and simi lar organizations. Each year, over 40,000 death and 250,000 serious injuries occur on th highway.[1]

In a study of patients admitted to the Massa chusetts General Hospital for the treatment of a acute injury, Tannenbaum[2] found that more tha 25% had a concurrent disease of significant im

83	Hip fracture and head injury	Cardiac seizures	Supportive	Died with pulmonary edema	2

ortance, often previously unsuspected. He demnstrated that the association of concurrent disase with the production of accidental trauma can e quantitated. The incidences of concurrent disase in the patients we studied were almost idenal to those found by Tannenbaum, even though ur patients were private patients (his, ward paents) and our patients were from a fairly large rea (his, from a single metropolitan area).

Because of the high incidence of concurrent isease, when any injured person requires hospitalization a complete history should be taken and a complete physical examination, with adequate laboratory studies and roentgenograms, should be performed, all as rapidly as the emergency allows. There should be no exception to this practice if an anesthetic is to be given for a surgical procedure. Often the advice of an internist or pediatrician may be helpful for additional overall evaluation of a patient who is seriously injured.

University of Minnesota

Course on Recent Advances In Infectious Diseases

The Department of Medicine and the Office of Postgraduate Medical Education of the University of Minnesota announce a course "Recent Advances in Infectious Diseases" to be held at the Mayo Memorial Auditorium on the Minneapolis Campus October 12 to 14, 1972 in honor of Wesley W. Spink, Regents' Professor of Medicine and Comparative Medicine.

The course will offer recent information on detection, management and prevention of serious infectious diseases in man. It will include a broad view of the biology of infectious agents and host responses. Several related clinical problems in each of five general topics will be reviewed in depth. Topics will include Gram-negative Sepsis, Pyogenic Infections, Zoonoses, Respiratory and Streptococcal Disease and Immune Deficiencies. There will be time for questions and several panel discussions. The course is designed for physicians engaged in the practice of general medicine and the clinical management of infections in children and adults. The tuition is $125.00. Residents and fellows-in-training $80.00.

Further information may be obtained from James M. Schless, M.D., Director, Postgraduate Medical Education, University of Minnesota Medical School, Minneapolis, Minnesota 55455.

Members and Fellows of The American College of Physicians should apply to the Registrar, Postgraduate Courses, ACP, 4200 Pine St., Philadelphia, Pennsylvania 19104.

The Buckling Knee Syndrome

BROR S. TROEDSSON, M.D.

"Buckling Knee Syndrome" is a condition in which the patient complains of the knee giving way without any forwarning, and without the patient usually being able to give any definite cause. The case report may be cited as an example. The patient had had his left hip fused in 1954 and did well until June, 1970 when his left knee started to give way or buckle under him. All Xrays were negative except for the fusion of the hip. A neurological examination was negative. The patient was found to have tender and indurated areas in the left vastus lateralis, and rectus femoris (Figure 1). He had tried to strengthen his thigh muscles by exercises, but without any improvement.

To discover the changes in the muscles, which the patient as a rule is not aware of, it is helpful to grease the skin on both thighs with cold cream or cocoa butter. Both thighs are palpated simultaneously, and the tender, indurated areas in the muscles are then felt on the buckling side. Occasionally a patient may have buckling of both knees, and then the condition is felt in both thighs. It occurs in both men and women. The simplest case was that of a woman who was referred to us after a fall and who walked "stiff kneed" to prevent another one. In her case only the vastus lateralis area appeared involved, with the described induration and tenderness present. She was treated promptly with radiant heat and massage to the vastus lateralis area and recovered after five treatments. No other orthopedic diagnosis was entertained.

Since 1955 a total of 35 patients with a complaint of "knee buckling" or "giving way" have been seen. The ages were from 24 to 79. All but two were male veterans, the latter making up the bulk of the practice. Duration of complaint was from one week to fifteen years, average two years and ten months. Right side was involved in ten cases, left side in 21, and four were bilateral. The consistent finding in all of them was the tender hard oblong area in what appeared to be the midportion of the vastus lateralis.

Accompanying conditions or diagnoses were: Amputation of other leg (2), arthritis of knees (3), alcoholic neuritis (1), back and hip operation (2), bursitis of leg (1), chronic backache (1), diabetic neuropathy (1) had a fall (2), possible herniated disc (4), multiple sclerosis (3), muscular dystrophy (1), myotonia congenita (1), old disc operation (3), old postoperative subdural hematoma (1), old fracture of other leg (1), old cervical fractures (1), periarteritis nodosa (1), peripheral vascular disease (1), recovered old quadriplegia (1), Reiter's syndrome (2), residuals of fractured spine (1), and spondylolithesis (1).

All of the patients were referred to us either with one of the above diagnosis or with statements like these: "Has difficulty walking," "Weakness in leg," "Pain in lateral thigh," "Persistent leg pain," and "Status Post-L5-S1 hemilaminectomy." This shows the uncertainty about the diagnosis and the site of the trouble. The physiatrist has to take a detailed history and make a careful physical examination in order to find out the actual complaint and the location of the lesion.

The difficulties these patients have and the ease with which one can ascribe the symptoms to a concomitant condition is well illustrated by the oldest case.

Fig. 1—Area of tenderness and induration generally found in the lateral thigh in the Buckling Knee Syndrome.

Case Report

A 79-year-old man, seen August 14, 1969, complained of his right knee buckling off and on for three ars. He had a brace on the right knee and used a rearm crutch to prevent falling (Figure 2). The history as long and involved, starting with a fall in 1941, llowed by backache and treatment of a "slipped" disc, ithout hospitalization. He was first seen at our hospital 1962, complaining of back pain and right leg pain d had 12 admissions from 1962 to 1969, inclusive. uring these admissions, the following diagnoses were ade: Chronic low back pain, possible herniated disc, to-scoliosis of lumbar spine, degenerative arthritis of ine and peripheral joints. In 1964, a myelogram was ne showing an extradural lesions at L3-L4 level. He as operated on for herniated disc, but none was und. Decompression was done. For a while his comaint disappeared, but then pain started on the side the right thigh and down to the knee. The knee was eak at this time, but did not buckle. It started to ckle in February, 1967. He had had many different rms of treatment without getting better. In June, 1968, had a McMurray osteotomy of the right hip with sertion of a Harris compression splint. This was moved in March, 1969. The knee still buckled under im in spite of the fact that he had had gait training nd strengthening exercises to his right hip muscles, ductors, flexors, and extensors. On examination, paent's knee was found to buckle at a flexion of 30-40°. oth quadriceps muscles were found strong, the left ightly stronger than the right, but with adequate rength. Slight but equal crepitation was present in oth knees, but there was no swelling or tenderness round either. Careful palpation of the right thigh uscles disclosed (with the skin oiled,) a four-inch long nd half inch wide, tender, thickened area in the midortion of the lateral thigh. This appeared to be in e vastus lateralis portion of the quadriceps femoris uscle. There was not any such area on the left side. here was an operative scar over the right hip and ver the lumbar spine. Muscle strength test showed a trength of 31½ pounds in the right quadriceps and 37 ounds in the left. A diagnosis of fibrositis of the right astus lateralis was made. The patient was started on adiant heat and massage to the right vastus lateralis nd isometric progressive resistance exercises to the uadriceps femoris muscle complex. After five treatnents, the patient could walk around without his knee race and with only very little support from his Canaian crutch. The quad strength measured 41½ pounds ilaterally at this time. Treatment was continued with icycle exercises added, until he had a total of 18 reatments. He could then walk around on flat ground, p and down ramps, up and down stairs without the nee buckling. He still felt a little unsure of himself ecause his balance was poor and he liked to carry a ane around as a safeguard. The quadriceps strength t this time was 46½ pounds. The patient was disharged one month after admission. He was seen again ix weeks later and had had no recurrences of his knee uckling.

The buckling or giving way of the knee has been described as occurring in many conditions. Thus, Rosenblum, et al,[1] described a number of cases, cited other authors, in which the condition had followed hysterectomy. They ascribed the condition to pressure of the retractor blades on the greater psoas muscle with production of ischemia of the femoral nerve supplying the quadriceps femoris. They stated that the neural condition needed to create little concern, for it was almost always reversible. Our cases, of course, were not of this nature and presented no evidence of detectable femoral nerve pathology. Other conditions in which buckling of the knee has been present are cited by many authors. Thus O'Donoghue[2] and Cane[3] point out its possible presence in injuries to the menisci, but with it there is also a history of injury, local tenderness, pain and swelling of the knee. Our cases did not fall in this group either, but showed only one uniform finding of tenderness and induration in the vastus lateralis area. In spite of diligent search of the literature, we have been unable to find any reference to this condition. It is not mentioned by Steindler,[4] Mercer,[5] or Reno[6] under our sympto-

Fig. 2—A 79-year-old man with a buckling knee for two and a half years used a knee support and a crutch to prevent falling.

matic diagnosis of "Buckling Knee." We have not been able to find any reference to this condition under our pathological diagnosis of "Fibrositis." It is not mentioned by Adams,[7] Buckley,[8] Collins,[9] or Slocum.[10]

In investigating this distinct condition we had electromyograms done on two patients. There were no abnormal findings. A biopsy of the vastus lateralis on one case showed no abnormal findings.

Our observations lead us to believe that some loss of strength in the affected thigh may be due to disuse. Buckling of the knee occurred in those cases where we measured it at a knee flexion of 25° to 40°. We have under observation one patient who has had a buckling knee since 1962. He has been seen frequently, has not had any treatment and still has his buckling knee with the typical tenderness and hardness on the lateral side of the thigh.

It is our opinion that skillful massage is most important. One patient had had many kinds of previous treatments, whirlpools, diathermy, strengthening exercises, walking, medications, injections, and an operation, without any essential improvement. With heat and massage, the hardened area could be felt to decrease in tenderness and size until it was practically gone. We used strengthening exercises also. In regard to the location and the nature of the lesion that we are dealing with, we consider it to be a so-called *fibrositis* of the vastus lateralis of undetermined etiology. It feels like other fibrositic areas occurring in neck, back and leg muscles. It responds to heat and massage as other fibrositic muscles do. The process may involve the intermuscular septum and the muscle origin on the femur and may also involve the vastus intermedius and the iliotibial band. To us it seems that the primary lesion is in the vastus lateralis. As to the causative factor we can only speculate. The process does not seem related to any neurological condition or we would find it consistently associated with neurological findings. We have always thought it to be in the nature of an inflammation, but our one biopsy failed to show this condition, though that does not rule it out. The possibility of a virus, a local allergy, an enzymatic or some local metabolic disturbance is a possibility. In a way, the condition acts very much like an epicondylitis in the elbow. In this condition the patients suddenly drops something that he is holding, such as a glass of water. There is no pain, no premonitory sign. When examined, these patients have a hard tender area in the wrist extensors and tenderness over the lateral epicondyle of the elbow. Individual muscles in the forearm are found amply strong to hold a glass of water. However, in some way at a certain point there is an interruption in the neurological co-ordinating mechanism, the muscles lose their power momentarily, and the glass drops out of the hand. The same mechanism seems to be present in the Buckling Knee. There is a controversy as to the nature of these lesions. They are called fibrositis, myositis or muscle spasm, and their existence is denied by some. However, they do exist and are capable of causing great disability as demonstrated by many of our patients. Of the 35 cases seen, we had the opportunity of treating 25. Only one did not get much better. He was a post-hemilaminectomy case with bladder and bowel difficulties and tenderness over the sacro-iliac joints, in addtion to his vastus lateralis tenderness. After four and a half weeks of treatment he estimated he was 25% better. The other 24 patients improved to the point where they could discard wheelchairs, crutches, walkers, canes and the knee did not buckle any more.

Obstructive Airway Disease

Resting and Post-Exercise Spirometry

NELSON A. PAGUYO, M.D., SUMNER S. COHEN, M.D. and
JEROME T. GRISMER, M.D.

THE PHYSIOLOGICAL BASIS of exercise has been studied by numerous investigators since the recognition of it's beneficial effects in normal subjects.[8,19] The rationale of its use as an adjunct in total management of patients with cardiac, vascular, respiratory, musculo-skeletal and cerebral abnormalities has been extensively discussed in the literature. Barach,[2] Itkin,[9,10] Miller,[11] Naughton,[12] Paez[13] and Pierce[16] have shown the advantageous effects of exercise in the treatment and rehabilitation of patients with various pulmonary diseases.

Although the precise mechanism of improvement following exercise is not known, certain explanations have been advanced. These are:[13,16] (1) increase in muscular efficiency, (2) increase in neuromuscular co-ordination, (3) improvement in cardiac, pulmonary, and vascular functions, (4) increase in efficiency of the neuropituitary-adrenal axis, and (5) possible changes in the balance between aerobic and anearobic metabolism due to a more active oxidative process during exercise.

Materials and Methods

All patients in the Emphysema-Chronic Bronchitis Clinic having their routine trimonthly followup examinations from June 11, 1969 to November 11, 1969 were included. A total of 96 cases were analyzed. These patients had been followed from nine to 30 months and were considered proficient in the use of the treadmill and the Stead-Wells Spirometer.

A trimonthly followup consisted of a brief review of the patient's history, complaints, clinical progress, medications, physical examination, resting spirometry and treadmill exercise. The study included essentially the same procedures except with the addition of an immediate post-exercise spirometry performed within five minutes after completion of the treadmill exercise.

The ability to perform treadmill exercise varied widely from patient to patient. However, each patient was encouraged to accomplish to their maximum exercise tolerance.

Resting and post-exercise spirometry were then compared. Indirect maximum voluntary ventilation (MVV) was calculated with the formula introduced by Kennedy[6] $MVV = FEV_{0.75} \times BTPS \times 40$. (FEV is forced expiratory volume and BTPS means body temperature, pressure, saturation.)

A 10 percent or greater change between the resting (control) and post-exercise values was arbitrarily considered significant. The patients

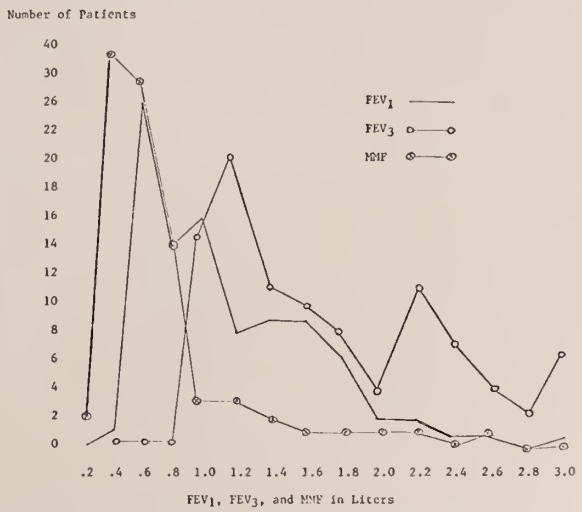

Figure 1—Patient distribution in the resting stage, One-Second Forced Expiratory Volume (FEV_1), Three-Second Forced Expiratory Volume (FEV_3), and Mid-Maximum Flow Rate Plotted Against the Number of Patients. Fifty-six patients are in the range between 0.6 to 1.0 Liter FEV_1, 55 between 1.0 to 1.6 Liter FEV_3 and 67 between 0.4 to 0.6 Liters MMF.

Mount Sinai Hospital Emphysema-Chronic Bronchitis Clinic.

were then classified as: (1) Group A. those who demonstrated 10 percent or greater improvement, (2) Group B: those who remained relatively unchanged, and (3) Group C: those who became worse by 10 percent or more.

Results

The data are summarized and illustrated as follows.

Figures 1 and 2 describe the severity of the obstructive disease in the group studied. More than 55 percent of the cases fell within the following ranges; (1) One-second forced expiratory volume (FEV_1) 0.6 to 1.0 liter; (2) Three-second forced expiratory volume (FEV_3) 1.0 to 1.6 liter; (3) Maximal mid-expiratory flow rate (MMFR) 0.4 to 0.6 liter; (4) Maximum voluntary ventilation (MVV) 15 to 30 liters per minute.

Figure 2—Patient Distribution in the Resting Stage—Maximum Voluntary Ventilation. Fifty-four patients are between the ranges of 15 to 30 liters per minute.

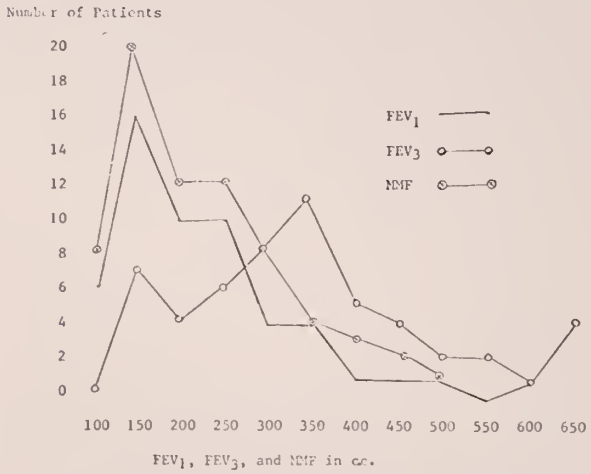

Figure 3—The Range of Improvement of Patients in Group A. The difference between the resting and post-exercise spirometry of Group A is plotted against the number of patients.

Table 1 summarizes the distribution of the patients into the three groups after exercise. 67 percent, 56 percent, 70 percent, and 60 percent of patients studied improved in FEV_1, FEV_3, MMFR, and MVV respectively.

Table 2 shows the average changes of the three groups after comparing the resting and post-treadmill spirometry.

Table 3 is a comparative study of the mean values of the 96 resting spirometry (control), the resting spirometry of the improved group (Group A) and the actual improvement of Group A following exercise.

Figures 3 and 4 illustrate the ranges of the difference between resting and post-exercise values of Group A patients along the ventilation parameters analyzed.

Discussion

The patients included were all diagnosed emphysema and/or chronic bronchitis. The majority represented advanced chronic obstructive airways disease with functional classification of III to V. Prior to this study, these patients had intensive treatment consisting of oral drugs, inhalation and physiotherapy. Regular physical exercises were stressed to the patients as an important factor in rehabilitation from the time they were started on the treatment program. After nine to 30 months of therapy, a significant segment of our patients were still unimpressed with the beneficial effects of regular physical exercise.

The effect of exercise was studied by a comparison of resting and immediate post-treadmill spirometry. The initial findings in a few patients were considered significant so that the study was extended.

The data (Table 3) indicate that the resting spirometry values of the patients in Group A are lower than those of the control. This implies that the patients who actually improved with exercise are the most advanced cases in our study group. The mechanism of this improvement is not known. Based on previous findings, however, one can only present theories possibly explaining the above observations.

Refsum[17] studied the respiratory response to

acute exercise and found that there is a remarkable increase in ventilation, which is due primarily to an increase in tidal volume. Briscoe,[3,4] Cohn,[5] Penman[15] and many others have documented the existence of a spectrum of regional ventilation-perfusion imbalance in patients with chronic obstructive airways disease (C.O.A.D.). This inequality between the alveolar ventilation and pulmonary capillary perfusion apparently is most pronounced at rest and improves with exercise.[5] This uneven ventilation-perfusion ratio may be sufficient to produce hypoxemia which in turn causes increased airways resistance in patients with C.O.A.D.[14] In view of these observations, one can presume that the increase in the post-treadmill exercise spirometry of patients in Group A can be explained satisfactorily on the basis of increased ventilation, improvement in ventilation-perfusion ratio and relief of hypoxemia to near normal or normal levels resulting in decreased airways resistance and possibly relaxation of bronchospasm.

Another explanation that can be advanced involves the concept of alpha and beta adrenergic receptors, first proposed by Ahlquist.[1] According to this concept, stimulation of the alpha receptors leads to a variety of reactions including constriction of vascular smooth muscle and increased automaticity of the heart. Stimulation of the beta receptors, on the other hand, results in an increased chronotrophic and ionotrophic action of the heart, bronchodilation and relaxation of

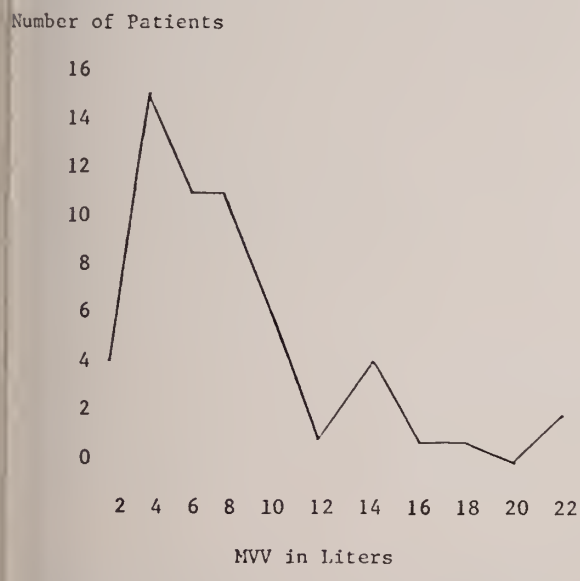

Figure 4—Distribution of Group A patients with their improvement in liters per minute after exercise.

TABLE 1

Classification of Patients After Exercise. Comparing the resting and post-treadmill exercise spirometry, patients were categorized into Group A (10% or more improvement), Group B (unchanged), and Group C (10% or more worse). The Table shows that the majority improved and a very few became worse.

Classification	FEV_1	FEV_3	MMF	MVV
Group A	55 (57%)	54 (56%)	70 (73%)	58 (60%)
Group B	37 (39%)	39 (41%)	20 (21%)	37 (39%)
Group C	4 (4%)	3 (3%)	6 (6%)	1 (1%)

TABLE 2

The Averages of the Changes in Spirometry Tests of the Three Groups after Exercise. The differences between the resting and post-exercise spirometry were obtained and averages determined. The plus (+) and minus (−) signs before the numbers designate the average improvement or deterioration of each group.

Classification	FEV_1/cc	FEV_3/cc	MMF/cc	MVV/L
Group A	+204	+319	+201	+8.0
Group B	+ 46	+ 51	+ 6	+1.4
Group C	−152	−213	−270	−8.6

TABLE 3

Comparison of the Average Values of the Control, Group A, and Actual Improvement in Group A.

	FEV_1/cc	FEV_3/cc	MMF/cc	MVV/L
Control	1022	1650	560	34
Group A	845	1472	485	30
Average Improvement	204	319	201	8.0

the vascular smooth muscles. The catecholamines (norepinephrine, epinephrine and isoproterenol) may be divided as an alpha or a beta stimulating agent. Norepinephrine is mainly an alpha receptor stimulator and isoproterenol, a potent beta receptor agent. Epinephrine acts on both alpha and beta receptors.

With the advent of a histochemical fluorescence technique for the localization of monoamines,[7] Weiner[18] recently reported that the bronchial smooth muscles are sparsely innervated by adrenergic neurons. Adrenergic neuron apparently stores norepinephrine which is released by stimulation of the nerve. Weiner postulated that under stress situations, cathecholamines, notably epinephrine, are discharged from the adrenal medulla. Because of the rich vascular supply of the bronchial tree, epinephrine is more likely to reach the bronchial muscles in higher concentration than the norepinephrine released from the scantily distributed adrenergic neurons. The result is more of bronchodilation than bronchoconstriction.

The exercise imposed on our patients constitutes a form of stress situation. This may explain why the most advanced cases in our study showed significant improvement following treadmill

exercise.

Summary

Ninety-six patients with proven chronic obstructive airways disease were studied. Resting and immediate post-treadmill exercise spirometry were compared. More than 55 percent of the subjects improved. Those who improved constitute the more severe cases. An explanation of this phenomenon is discussed.

'Tis a small matter in your neighbor's case,
To charge a fee for showing him your face;
You skip up-stairs, inquire, inspect, and touch,
Prescribe, take leave, and off to twenty such.
But when at length, by fate's transferred decree,
The visitor becomes the visitee,
Oh, then, indeed, it pulls another string,
Your ox is gored, and that's a different thing!*

Psychiatry

The Suicidal Physician

WERNER SIMON, M.D.

WHY DO PERSONS in a profession in which the goal is preservation of life kill themselves? Blachly et al.,[1] who have done a great deal of work on this subject, present some factual data. In a study published in the Bulletin of Suicidology, from May 1965 to June 1967, they reported that suicide was the cause of death of 200 of the more than 7,500 physicians who died. The average age of the suiciding physician was 49; the preferred method was the use of drugs; the average incidence was 36 per 100,000 among physicians compared with an average incidence among the average population of 11 per 100,000. The lowest incidence among the specialities was among pediatricians—10 per 100,000; the highest incidence was among psychiatrists with 61 per 100,000. In breaking down some of Blachly's figures, one finds the distribution among various medical schools of great interest. It so happens that the University of Minnesota provided the highest figure with 10; next to this Colorado with 8; and then Illinois, Harvard, and Pennsylvania with seven each. When one examines these figures more closely, one finds that certain graduating classes from particular years form definite clusters. For instance, in Minnesota the years 1934 to 1936 provided most of the completed suicides.

Physician Suicide at Veterans Hospital

Several years ago we studied at our hospital suicide among physician-patients.[2] We had 36 physicians as psychiatric patients and were very much interested in the outcome of our treatment for our follow-up information. We were aware of the increasing incidence of suicide among physicians and noted the trend with mounting concern. A survey of patients treated on the In-Patient Service at our hospital, covering a span of 20 years, revealed that 36 physicians had been patients and follow-up inquiries yielded the information that five of them, or 13.8%, subsequently committed suicide. We made a special study of these five patients to elucidate any factors which might have been useful in predicting the high suicide risks among them in contrast to others who revealed suicidal preoccupation during their hospitalization but did not commit suicide. In other words, we did what is currently known as a "pychological autopsy." We studied them with Minnesota Multiphasic Personality Inventory (MMPI) profiles and found the group profile for the physician-patients who had suicidal preoccupation to be in marked contrast to that found in other studies of suicidal preoccupation. The physician-patients differed from other psychiatric patients with suicidal preoccupation in that the physician-patient tended to deny personal distress or psychological discomfort. The propensity toward suicide in the physician-patients seemed to be well covered and in this sense made them much more difficult treatment prospects. Three of our five patients who committed suicide had a diagnosis of manic-depressive illness; they had many recurrent episodes, had had much intensive therapy, and suicide for them could have been interpreted as one possible response to insoluble emotional problems. This was before lithium therapy had been introduced. Nowadays with lithium the outcome might have been different, as newer studies[3] indicate that lithium is capable of preventing recurrent episodes of manic-depressive disorder. The other two suicides carried the diagnosis of personality disorder and were characterized by episodes of acting-out behavior. These patients showed marked defensiveness in admitting their psychological problems and because of their elaborate denial system closed themselves off to any therapeutic intervention. These two diagnostic catagories, according to our study of physician-patients, constitute a high suicidal risk. None of our neurotic patients committed or even attempted suicide. Also, and this was somewhat surprising to us, no schizophrenic patient in

Paper presented at Hadassah University Hospital, Jerusalem, Israel, on March 17, 1972.

Dr. Simon is Clinical Professor of Medicine and Psychiatry, University of Minnesota Medical School. He was formerly Chief, Psychiatry Service, Veterans Administration Hospital, Minneapolis.

our study ended his life by self-destruction.

In another investigation[4] we studied these same patients from the standpoint of alcoholism and drug addiction, which we considered a possible attempt at chronic self-destruction. Since the rate of suicide was 13.8% among our physician-patients and this figure is higher than the 8-9% suicide rate cited in earlier reports for physicians who were drug addicts, it seemed that drug addicts do not commit suicide as frequently. It is well known that the incidence of drug addiction among physicians is much higher than in the general population, both in the United States as well as in Europe, and it has been called an occupational hazard. In our investigation, we found the incidence of alcoholism and drug addiction among our hospitalized physician-patients to be very high. The figure for alcoholism was 69% and for drug addiction 58%, much higher than in any other reported studies. Thus it appeared that alcoholism and drug dependence were much more frequent among physicians who are veterans. One might well speculate that the rate is most likely to be much higher for veterans returning from Vietnam. Alcoholism and drug addiction occurred in the following diagnostic groups in order of frequency: (1) neurotics, (2) personality disorders and (3) psychotics. Again, we found that addicted physician-patients generally were markedly defensive and had a very elaborate denial system closing themselves off to any effective therapeutic intervention. An assessment of this defensiveness was attempted with a special research scale in the MMPI. This proved to be the highest for those patients with histories of addiction and lowest with no such history. This could be explained on the basis of omnipotence, through feelings of being immune to death or suicide. Cantor[5] has pointed out that certain forms of death-play are not recognized by society as suicide but are permitted as normal behavior to overcome the fear of death. Such play, for instance sustained alcoholic intoxication, can become a suicidal equivalent. However, if one can break through this defensiveness and get physician-patients to admit their psychopathology, the outcome appears to be more favorable. This is fortunate, as suicide is irreversible, whereas drug addiction can be reversible. Initially patients will deny that their addiction is a suicide substitute or that they have any psychological problems, but later in retrospect they will often acknowledge and recognize their death wishes. At times, addiction may appear to have a hopeless prognosis to patients and their families. However, our study shows that as many patients with good outcome on follow-up had histories of chronic alcoholism and/or drug addiction as did poor outcome patients. Our findings support the results of Small et al.[6] who report that almost half of the alcoholic and drug-dependent physicians return to regular full-time medical practice.

The Suicide-Prone Physician

When one asks the question how does one recognize a physician who is in danger of suicide or who is contemplating suicide in order to take steps to intervene or to prevent this tragedy, various authors give us different clues as to how to recognize such symptomatology.[7,8] For instance, suicide-prone physicians often seem more interested in their work than in their home lives and they frequently neglect their wives and children. They very commonly have marital problems. It is true that long hours of practicing can cause in some people considerable exhaustion so that they are unable to share the daily concerns of wife and children. When the physican's wife pleads with him to take more time away from work, this can lead to further problems and conflicts. Being married to a practice becomes particularly risky for physicians with a tendency toward self-destruction.[9] When one considers that physicians are on-call 24 hours a day and are expected to perform at maximum efficiency at all times—this puts the physician under great physical and psychological stress—more so than members in other professions. Many physicians turn to drugs because of overwork and pressure. The progression from severe practice demands to stimulants and to eventual self-destruction has also been outlined by Blachly[1] as beginning with annoying physical symptoms and leading to severe mood swings, reluctance to accept society's restraints, and finally dependence on drugs or alcohol. Not all drug or alcohol abusers end in suicide, nor do all suicides have a history of such dependence, but the correlation is quite common. Litman[10] of the Los Angeles Suicide Prevention Center, estimates that about half of all physician suicides are preceded by misuse of alcohol or drugs or both.

How does one recognize the suicidal physician if he uses drugs? It is difficult unless he is caught red-handed. He finds it hard to ask for help

because he might consider it weakness. If he decides that he must take action, he usually will not go to another doctor but rather treat himself. He will not admit to his wife that he is dependent on drugs. He will absolutely refuse to see a psychiatrist. Neither will he confide in a family physician or colleague friend for fear that word might get around and his license might be suspended. When he tries to interrupt his habit, the result is usually withdrawal symptoms, severe depression and guilt, and soon he goes back on drugs as an emotional crutch to combat these symptoms and often then is forced to increase his former dosage.

There is an important age factor. A high risk period, for instance, occurs when a young physician leaves the protected environment of residency to face the responsibility of establishing himself in practice. Another high risk period exists when the physician nears retirement and he may view life as not worth living without the gratification he has had from his medical career. The average age of maximum stress and anxiety for many physicians is 49, according to Blachly.[1] It is the time when parents are dying, when children are leaving the home, when chronic marital difficulties become more intense, and competition of younger colleagues is becoming apparent.

The Danger Signs of Suicide

What are the warning signs which can be detected? If a physician has a close relationship with a colleague, an associate, or a personal friend, then it might be easier to communicate his feelings and possibly his preoccupation and intent. The physician who is a particularly high risk for potential suicide is one who has suffered severe personal loss, such as a death in the family, divorce, loss of health, professional reversals, and diminished prestige. The outward manifestation and symptomatology may be apathy, loss of appetite, depression, loss of weight, insomnia, agitation, sometimes outwardly noticeable changes. Giving away possessions which have meant a great deal, or making statements such as the family might be better off without him, can be revealing. Personality changes can be apparent,[11] even to other colleagues, but what is usually quite obvious is the over-use of alcohol and drugs. Signs in appearance and behavior occur which make the knowledgeable person suspicious: inability to remember clearly, tremors, extreme signs of fatigue, carelessness about dress, slurred speech, difficulty in talking, overuse of amphetamines, refusing to rest or relax. He becomes forgetful, uses unusual therapeutic procedures which do not seem to be indicated, and his attention wanders when a discussion is attempted.

Physicians deny any sign of their own illness and colleagues hesitate to intervene. If one can break through the defensiveness and encourage physician-patients to admit their psychopathology, the outcome is more favorable. How can this be accomplished? Most drug-dependent patients use the technique of a pattern of self-defense called procrastination supported by a system of rationalization. Since this is largely a conscious type of defense mechanism, it should be attacked directly by confrontation before psychotherapy is begun. The success of doctors' groups with Alcoholic Anonymous begins with the liquidation of the "alibi system." Inasmuch as physicians are familiar with all the physical, neurological and cerebral complications of alcoholism and drug addiction, it would appear that addiction is deliberate self-destruction for them. However, many therapists treating physicians assume that "the doctor ought to know" and do not prescribe definite treatment as if expecting self treatment. It is essential that a trust relationship be established in which it is safe for the physician-patient to surrender himself into the care of his therapist, overcoming denial, and giving up any omnipotent traits. Sometimes a successfully treated physician "who has been through it" becomes a most effective therapist. It may be helpful to bridge the gap by allowing the physician-patient to be a cotherapist in his own treatment by individualizing his own medication in the face of anticipated stress situations, as Small and others[6] have suggested. But this can also be a risky procedure. It must be remembered that practically all of the alcoholic and drug-dependent physician-patients are depressed and should be treated for depression, once a break-through of the defensiveness is accomplished. Initially the patients will often deny that their addiction is a suicide substitute or that they have any psychological problems. Later on, in retrospect, they will often acknowledge and recognize their death wishes.

Treatment

Getting a troubled physician to admit that he needs professional help, and then to seek it, is a hard step to take. If he finds someone he can

trust, with whom he can ventilate his feelings and disclose his moods and disappointments, it becomes much easier. Blachly[12] is in favor of confrontation and believes it can be effective. He proceeds subtly by indicating that he knows something is wrong and asking if he wants to talk about it. He states that a surprising number of physicians have been talked out of suicide by being made aware of the economic and realistic consequences of such an act. Many lives could be saved if we were not prone to stop short of such difficult but often necessary extremes as hospitalization, shock treatment, or even arranging for possible legal action such as commitment.

The emotional screening, education and self-awareness should begin, not at age 49, but in medical school. Schofield[13] has studied medical students at the University of Minnesota and describes the future physician who is in danger when looked at as a freshman or junior medical student. Their MMPI profiles might be predictive of future maladjustments. He found that with aptitude variance controlled, the underachievers were characterized by "a tendency toward unrealistic appraisal of their environment, unhappy social relationships, and autistic ruminations." These same underachievers also showed general tendencies toward relatively unsophisticated denial of personal weakness and the expression of idealized self-concept. Such persons may be expected to respond to intense role strain with increased vulnerability, and if the paranoid defensiveness scale is found to be elevated, one might hypothesize an increased liability toward suicidal preoccupational behavior.

What psychopathology do physicians who later on commit suicide show? Modlin and Montes[14] studied their physician-patients at the Menninger Clinic and found that as children they had been sickly; that in adolescence they were very studious, ambitious, and did well scholastically; but their married lives were depicted as ambivalent an dependently attached with much marital an sexual conflict. Their personalities were describe as basically insecure with unrealistic aspiration and vulnerable self-esteem. They denied any lim itations, although showing many signs of fatig ability and energy-draining neurotic struggles, re sulting in becoming tired of giving and ambivalen toward medical practice. Duffy,[15,16] who studie physicians admitted to the Mayo Clinic as psychi atric patients, reported that denial was a commo mechanism in therapy, with overt hostility towar the therapist quite frequent, manipulation of th environment with many demands, and the use o alcohol and drugs as a defense against overwhelm ing anxiety were common. The extreme resistanc to admitting his psychopathology and acceptin psychiatric treatment seemed most characteristi of these physician-patients.

The problem of the emotional health of physi cians has become so much of a concern that special panel of psychiatrists considered this topi at the 1967 American Psychiatric Associatio meeting. Medical societies in their regular meet ings should have special symposia where thi occupational hazard, suicide among our col leagues, should be considered and discussed Physicians are no more immune from emotiona problems then they are from physical illnesses Many professional "suicidologists" recommen an annual emotional check-up. Many medical so cieties send out annual reminders for regula physical examinations to their members and i would be a good idea to include an emotiona inventory at the same time. Industry has begu to think in terms of psychological examinations a regular intervals for their executives, and th Menninger Clinic, for instance, has many indus trial executives going there each year for an emo tional check-up. The same thing can be don for physicians.

If you've seen one, have you really seen them all?

The following patient profiles represent typical clinical situations, but do not necessarily represent actual cases.

Age 22, previously normal me
with occasional menorrhagia
on a sequential O.C. for four r
Complains of heavy flow,
occasional intracyclic bleedin
edema, tender swollen breast
Indicates estrogen excess
1st choice: Switch to a com
bination 50-mcg.-estrogen O
(such as **Demulen***).

Age 19, small breasts, minor hirsutism, oily hair and skin. History of metrorrhagia, skipped or scanty menses. New user.
Indicates androgenic excess or estrogen deficiency (fertility is suspect).
1st choice: An estrogen-dominant O.C. (such as **Enovid-E***).

Age 25, average frame, poor complexion. No problem with menses, normal para 1. On a low-estrogen/high-progestogen O.C. for two years. Now complains of scanty flow, decreased libido, depression.
Indicates probable buildup of progestogen-related side effects.
1st choice: Switch to a center-spectrum O.C. with more estrogen, less progestational activity (such as **Ovulen***).

Age 21, short, mammose, with normal menses, some acne. Was put on prenuptial regimen of 50-mcg.-estrogen/moderate-progestogen O.C. for two months. Now has increased acne.
Indicates metabolic production of androgen or relative estrogen deficiency.
1st choice: Switch to a 100-mcg.-estrogen combination (such as **Enovid-E*** or a sequential).

Unmasked, physiologically and anatomically, they're not all the same. A basic difference lies in their hormone profiles. One may secrete too much estrogen, another not enough...or perhaps too much androgen; the vast majority would fit somewhere into the broad center spectrum.

Although the profiles described below may not be completely predictive, in optimal O.C. selection, the estrogen-progestogen activity ratio should be carefully matched to the patient profile. Searle offers you O.C.s in a range not only suitable for your patients in the balanced center spectrum, but also adaptable to the patient with another type of hormone profile.

Oral contraceptives are complex medications. Among the commonly reported adverse reactions are: intracycle bleeding, fluid retention, tender or swollen breasts, exacerbation of acne condition, changes in libido, amenorrhea while on medication and upon discontinuance, nausea, leg cramps, headaches, weight gain. Therefore, after reference to the prescribing information, oral contraceptives should be prescribed with care.

*Note: In some patients any level of exogenous estrogen or progestogen may produce symptoms of excess hormone activity.

'5, tall, slender, athletic,
flat chest. On a progestogen-
nant 50-mcg.-estrogen O.C.
ecurrent trichomoniasis
Monilia.
dicates estrogen deficiency and
ss of progestogen in current O.C.
t choice: Switch to a com-
ion pill with 100 mcg.
s gen and less progestational
ity (such as **Enovid-E*** or
Ov en* or a sequential).

Age 23, "Miss America" figure, previously normal menses, healthy skin and hair. On a 50-mcg.-estrogen pill for four months. Complains of intracyclic bleeding.
Indicates probable need for more estrogen.
1st choice: Switch to a center-spectrum O.C. with more estrogen and moderate progestogen dominance (such as **Ovulen***).

Age 21, college senior, average build. On highly progestogen-dominant/low-dose-estrogen O.C. for six months. Now complains of amenorrhea, between-cycle headaches, weight gain.
Indicates probable progestogen excess.
1st choice: Switch to a center-spectrum pill (such as **Ovulen***).

Age 27, slightly overweight, multiparous. Nausea with all three pregnancies and with a sequential O.C. three years ago. Has pre-menstrual fluid retention and leg cramps.
Indicates probable excess of estrogen.
1st choice: A 50-mcg.-estrogen/progestogen-dominant pill (such as **Demulen***).

Ovulen® a balanced center-spectrum O.C. for most
Each white tablet contains ethynodiol diacetate 1 mg./mestranol 0.1 mg.

Demulen® a moderately progestogen-dominant O.C. for many
Each white tablet contains ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.
Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.
Both Ovulen and Demulen are available in 21- and 28-pill schedules.

SEARLE Products of SEARLE & CO.
San Juan, Puerto Rico 00936

Enovid-E® a moderately estrogen-dominant O.C. for some
Each tablet contains norethynodrel 2.5 mg./mestranol 0.1 mg.

a family of O.C. products to help you match the right pill to the right patient

Ovulen®

Each white tablet contains
ethynodiol diacetate 1 mg / mestranol 0.1 mg.

Demulen®

Each white tablet contains
ethynodiol diacetate 1 mg / ethinyl estradiol 50 mcg.

Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.

Actions – Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note – Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication – Ovulen and Demulen are indicated for oral contraception.

Contraindications – Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings – The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain[1-3] leading to this conclusion, and one[4] in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll[1] was about sevenfold, while Sartwell and associates[4] in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions – The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any possible influence of prolonged Ovulen or Demulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limiting factor, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood pressure following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives – A statistically significant association has been demonstrated between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalein retention and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine and decrease in T^3 uptake values; metyrapone test and pregnanediol determination.

SEARLE

Products of SEARLE & CO.
San Juan, Puerto Rico 00936

Enovid-E®

norethynodrel 2.5 mg / mestranol 0.1 mg

Actions – Enovid-E acts to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Enovid-E depresses the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Indication – Enovid-E is indicated for oral contraception.

The *Special Note, Contraindications, Warnings, Precautions* and *Adverse Reactions* listed above for Ovulen and Demulen are applicable to Enovid-E and should be observed when prescribing Enovid-E.

Enovid-E®

brand of norethynodrel with mestranol

Supplements to Minnesota Medicine
The Kinsella Supplement

With this issue, subscribers to Minnesota Medicine receive as a supplement, Kinsella's "History of Thoracic Surgery in the Upper Midwest." The Board of Editors from now on will occasionally accept for publication as a supplement manuscripts which are of interest to its readers, but cannot be included in the regular columns of the journal usually because they are too long. Supplements will not be a frequent feature of the publication and will occasionally appear perhaps once or twice a year.

Minnesota Medicine thanks St. Mary's Hospital, its staff, and friends who have supported this Kinsella supplement.

Tom Kinsella, in the upper Midwest, essentially created the field of thoracic surgery. He started out, however, probably with no intention of making a career out of surgery. He had a general internship at the Minneapolis General Hospital (Hennepin County General Hospital) from 1919-1920. His fellowship at the Mayo Clinic from September, 1920 to January, 1922 was in the field of internal medicine.* Immediately thereafter we find him in the Nicollet Clinic as assistant in surgery.

Training for one specialty and practicing another is unusual but well known in medicine and there are some brilliant examples: E. T. Bell who was formally trained as an anatomist and Cecil Watson whose Ph.D. was granted under Bell in pathology.

Undoubtedly Kinsella's bout with pulmonary tuberculosis was crucial in his decision to make this disease his principal interest. In a letter his widow, Sally Kinsella, writes: "He left the Mayo Foundation January 1, 1922. He was assistant in surgery at the Nicollet Clinic in Minneapolis for one year. That is when he broke down with T.B., and became associate physician at Cragmoor Sanitorium, Colorado Springs, Colorado until July 1, 1925." Apparently T. J. Kinsella was not only a patient with pulmonary tuberculosis at Cragmoor, but also a physician on the staff. His primary achievements in thoracic surgery, particularly in pulmonary tuberculosis are recounted in Cohen and Priest's forward to the Kinsella supplement.

A delightful interlude in my junior year in medical school was a month spent at Glen Lake Sanatorium, on the service of Tom Kinsella. That was in the early thirties and by then he was famous for his successful thoracoplasties. Patients pleaded to be accepted for surgery by him knowing this was the surest way to be released from the Sanatorium. In his examining chamber however he was an internist, paying full attention to the history and carefully going over every possible physical finding with his students. He was always first a physician.

Dr. Kinsella enjoyed a unique reputation, expert in the medical care and diagnosis of chest disease and peerless in their surgical relief.

*Terrace Topics, January, Vol. 1, No. 5 published by the Trudeau Club, Oak Terrace, Minnesota in 1934.

Doctor Thomas Kinsella

The History of Thoracic Surgery

Dr. Thomas Kinsella in his history which is published in the enclosed supplement lists many familiar men of medicine: Mixter, Plummer, Vinson, Rontgen, Wilms, Halsted, Estlander, Friedlander, Morgagni, Laennec, Virchow, Ochsner, Sippy, Kussmall, Billroth, Mikulicz, Blalock, Vineberg, Cushing, Dupuytren, C. H. Mayo, W. J. Mayo, and Nakayama. Surgical procedures, many unfamiliar, are included namely pneumonolysis, ligation of the pulmonary artery, therapeutic pneumothorax, surgery on the phrenic nerve, scalenectomy, and thoracoplasty.

There are accounts of interesting and fascinating cases, such as the one in June of 1898 when Dr. Eitel and Dr. Dunsmoor surgically removed a partial dental plate which had been impacted in the esophagus for six years.

The history is thorough. It takes the reader from the dawn of chest surgery to the most modern of advances, including transplant surgery. Interesting to note is that the heart pump goes back to at least 1928, and that experimentation with heart transplants goes back to 1931.

Many doctors, I suspect, feel that the world too soon forgets the accomplishments of its doctors, and a written history provides a way so that many can live a little longer. I am sure that Dr. Kinsella would have considered this a very weak argument, as this was not one of his motivating factors.

Those of us who had the opportunity of participating with Dr. Thomas Kinsella in the care of patients often felt the best part of all was the good doctor himself. Once again, the best part of his history is the personality of Tom Kinsella, himself.

Something of his whimsy is evident as he relates how Xray was demonstrated at the Minnesota State Fair in 1902, by Dr. A. A. Deslaurier, who was then a sophomore medical student and who had received the machine as a present from his father. You see the author as a detective ferreting out these many facts in order to credit the various advances to the proper people.

If the best part of the history is the author himself, then the best part of Dr. Kinsella was his feeling for his patients. You are left with the lasting impression after reading the history that Dr. Kinsella cared about people while he was caring for them.

Perhaps this is the greatest legacy a man can leave behind . . . his great love for people and his desire to make them well.

Excelsior, Minnesota

Familial Idiopathic Hypoparathyroidism

Doctors Olin and Poindexter* report direct attention to two points of practical clinical importance. The first is the necessity of physicians being aware that failure of one endocrine gland may herald the onset of failure of others. Further, the discovery of a patient with endocrine deficiency is indication for a careful review of families for other similarly affected members.

The second point reminds physicians that antibodies against endocrine glands may be present long before clinical and laboratory evidences of specific glandular failures are manifest. Although the presence of antibodies against a clinically unaffected gland undoubtedly has significance, it is not certain that all such patients will develop failure of all of the glands but surveilance for their possible failure is indicated.

Aorto-Iliac Disease—Small Arteries Syndrome

THE CLINICAL PROBLEM of occlusive disease of the aorto-iliac arterial system is presented by Rockwell.* The diagnostic work-up and treatment has become quite standard and is available in most major hospitals in Minnesota. The management of these patients must be individualized to a high degree due to the wide variations in the extent and location of the occlusive disease. A small number of patients presenting with aorto-iliac occlusive disease will be found to have "small artery syndrome." In this situation the aorto-iliac system (in addition to the entire arterial system) is smaller than in most individuals. Indeed, the transverse diameter of the abdominal aorta often runs 30% to 50% of normal. The accompanying arteriogram represents the aorto-iliac system of a 170 pound six foot male with an abdominal aorta measuring under one and one-half centimeters in transverse diameter. In individuals with "small arteries" the build up of atheromatous debris within the lumen leads to symptoms and findings of limb ischemia earlier than in patients with normal sized arteries. The principles of treatment, however, remain the same in all cases, namely to restore pressure and flow to the groin.

Arteriogram

Treatment of Bone Tumors in Children

DR. COVENTRY* has made a concise summary of the treatment of the most common bone tumors found in children. Much useful information also is included in regard to diagnosing these lesions.

The most important differential point is whether the lesion is benign or malignant and except for some of the more common and characteristic x-ray appearances biopsy is required to make this differentiation.

Survival rates in series of patients with osteogenic sarcoma and Ewing's sarcoma remain somewhat controversial. The 20 percent five-year and 17 percent 10-year survival quoted in this article is higher than the range of survival reported by most series. Some other series have reported five-year survival as five percent or less.

Osteogenic sarcoma and Ewing's sarcoma, the most malignant of the children's bone tumors fortunately are relatively rare. It is difficult to recall, however, a patient with either of these conditions who has survived even five years despite prompt diagnosis and amputation treatment. Nonetheless, to quote Dr. Dahlin, the relatively favorable data reported here "should help dispell the notion that the prognosis of osteogenic sarcoma is so poor that prompt and proper therapy is useless."

Teaching Medicine in Private Hospitals

MEDICAL EDUCATION in the undergraduate days of most of the readers of MINNESOTA MEDICINE was rather rigidly separated into basic sciences the first two years and clinical studies the Junior and Senior years. The junior year at Minnesota consisted of amphitheatric lectures by the professor to a seated class with perhaps one in a hundred called down to inspect, palpate, or auscultate. The house staff made rounds with attending and consulting professors taking notes of their suggestions (which really were orders) and following hierarchial protocol. That's how it used to be, but things are different now. Theologides* elsewhere in this issue discusses the curricular change and really revolutionary transformation in the medical school. The attitudes of medical students and student doctors have changed with profound effect upon academic teachers.

Now students in the freshman year are involved in clinical exercises. The old devil of the junior year shuttling students from Eustis to Todd Amphitheater is no more. Juniors are working in hospital wards, and Seniors are writing orders like interns. They are interns in every respect except nowadays they go home nights (most nights). One can predict the early demise of the traditional intern year.

The ferment among students affects not only those in academic medicine. The University of Minnesota accepted 227 entering freshmen medical students in 1971. This represents nearly double the number of a decade ago. Private hospitals are asked to share in the clinical training of these students and, indeed, already in Twin Cities hospitals are found phase B sophomores and junior and senior interns learning in small groups with "compassionate and expert physicians" as described by Theologides. With the new medical schools opening in Duluth and Rochester this year, clinical teaching in the communities will be done exclusively in private hospitals. In the private hospital the students can study patients not already violated by too numerous examinations. They learn. They also teach by asking difficult questions of the tutor.

It is possible also for the new breed of house staff to practice in the medical wards of private hospitals. The admitting physician discusses the diagnostic and therapeutic problems, listens to the house staff recommendations, and may suggest other studies, consultation, and therapy which will be actually written down as orders by the intern. This is not an easy role for the physician who admits (owns) the patient. It requires extraordinary restraint on the part of the senior staff and considerable understanding on the part of the house staff of the responsibilities of the patient's physician which are not abdicated by assigning the patient to a teaching service.

We are in a new era of medical education, not only within the university, but deeply involving private hospitals also. What Theologides has to say about academic internists applies also to an increasing number of non-academic internists and family practitioners who are involved in the clinical teaching of medical students. Physicians all over the state including such towns as Cloquet, Austin, Hibbing, and Montgomery have medical students living in their towns learning medicine at the "grass roots" level, so to speak. Right now, 23 such medical students are on this program. The end result of these programs extending undergraduate medical education to private hospitals and into family practitioners' offices must be better care of the patient.

Reuben Berman, M.D.

Meeting

The 32nd Annual AMA Congress on Occupational Health will be held at The Drake Hotel in Chicago, September 11-12, 1972. Contact Dr. Henry F. Howe, AMA, 535 North Dearborn Street, Chicago for further information and reservations.

Temporal Lobe Seizures

)R. RUSSELL B. BUTLER* presents an interesting view of temporal lobe seizures with emphasis n historical perspective and their anatomic substrate. Some points he raises would seem to arrant further comment.

Automatisms associated with temporal lobe izures may be clinically indistinguishable from ose occurring with associated generalized spike id wave discharges in the electroencephalogram, r from automatisms occurring after a generalized nic-clonic seizure. This lack of specificity of inically observed episodes may indicate that they sult from a release phenomenon rather than om a specific epileptic discharge through obcure motor pathways. It may be that when, as result of electrographic seizure discharge or ostictal suppression, critical areas of the brain re functionally disconnected from certain other reas, the latter areas are "released" and an automtism occurs. The association of the psychic henomena reviewed by Dr. Butler and the elecoencephalogram makes clinical differentiation asy in most cases.

Although it is true that some patients with temoral lobe seizures have disorders of personality r emotion or both, some careful studies measurng various parameters of psychologic and emoonal status have not shown consistent differences etween temporal lobe patients as a group and ther epileptics or nonepileptics. It is often almost mpossible to assess the cause of psychopathology in the individual patient with temporal lobe epilepsy. The disturbance may be an ictal or postictal phenomenon; it may be the result of anticonvulsant medications or the result of the same cerebral pathology that caused the convulsive disorder; or it may be a reactive emotional disturbance. Any or all of these factors may be acting at various times in a given person.

The rationale for prescribing primidone and phenobarbital concurrently is obscure. It is well established that the metabolism of primidone is considerably more complex than that of phenobarbital. The bulk of orally administered phenobarbital is excreted, unchanged, by the kidneys. Primidone is partially metabolized as phenobarbital (10 to 25%); but in addition, primidone itself and another of its major metabolites, phenylethylmalonamide (PEMA), have been shown to have anticonvulsant properties in experimental animals. Primidone therapy therefore has the theoretical advantage over phenobarbital therapy of giving these two additional anticonvulsants. For a given blood level of phenobarbital, higher levels of the other two (primidone and PEMA) can be achieved if primidone is prescribed alone. Despite its theoretical advantages, controlled crossover trials in epileptic patients have shown that primidone therapy is no more effective than phenobarbital therapy when the doses of each are such that blood levels of phenobarbital are kept constant.

William E. Karnes, M.D.
Rochester, Minnesota

Intussusception in Infants and Children

THE TREATMENT of intussusception has swung ike a pendulum between medical and surgical xtremes.

Prior to 1871, no successful operation had been erformed and the disease was almost always atal. In 1876 Hirschsprung of Copenhagen pubished his first report on the use of a hydrostatic ressure enema. His results were superior to any urgical series for nearly 70 years with a mortality of about 35 percent in contrast to the surgical mortality at that time of 80 percent.

After 1940 the pendulum swung to surgical therapy as improved technique, better anesthesia, and antibiotics helped to reduce the mortality well below that achieved by enemas alone. The barium enema in the next two decades was used primarily as a diagnostic tool with little attempt to reduce the intussusception.

Beginning about 1960 and continuing to the present time the pendulum has come to rest near the center. At the prodding of men like Ravitch, most surgeons now agree that a contrast hydrostatic enema under careful control, augmented by surgery when required, represents the best treatment of this disease. The thoughtful report by Thomas in the July issue is in agreement with this view.*

Still unanswered are several clinical observations which have intrigued me for many years concerning infants and children. Why does intussusception tend to occur in sturdy, well nourished "butter-balls" rather than in malnourished infants? Why are there seasonal peaks in the incidenc does it relate to adenovirus infection? Why th strong preponderance in males? Why does th disease peak between five to ten months of ag and sharply decline after a year? And, one fin perplexing question, why should there be a strikin variation in the incidence of intussusception in di ferent regions of the world? The British Isles an Scandanavia see a markedly higher incidence tha the United States. In this country we have regularl seen more cases in Minneapolis each year tha are reported from large centers in Baltimore, Ne Orleans and New York, indicating a definite r gional variation in the incidence.

Intramuscular Neurolysis for the Relief of Spasticity

INTRAMUSCULAR NEUROLYSIS as an adjunct in the treatment of spasticity, discussed by Awad in this issue,* has received scanty attention in the literature, probably because it is not being practiced widely.

At the Mayo Clinic, we began using phenol blocks of motor points of skeletal muscle in spastic patients four years ago and have employed this therapy in cases of multiple sclerosis, stroke, traumatic myelopathy, and cerebral palsy. The technique is mastered readily, especially by those with a background in clinical electromyography and, as noted by Awad, has proved to be free of significant local irritative and systemic toxic side-effects.

Our experience with intramuscular phenol blocks has varied. With few exceptions we have failed to provide relief in patients with myelopathy in whom the objective was to reduce massive flexor or extensor spasms of the lower extremities. We no longer treat this type of problem with chemical neurolysis. Better results have been attained when the aim was to reduce adductor or hamstring muscle spasticity or to lessen foot clonus that interfered with ambulation. The most satisfy ing results have followed treatment directed a highly selected muscle groups as in loosening a tightly folded thumb, opening a clawed hand, o reducing inverter or flexor spasticity of the foot Given a limited permissible amount of phenol pe treatment session, it is simpler to accomplisl clinically effective neurolysis when functional im provement depends on alleviation of spasticity i a single muscle or muscle group than in multipl muscle groups. Furthermore, some extremit muscles are located easier technically with th probing needle than are others.

Our initial enthusiasm for phenol blocks o motor points in the treatment of spasticity ha waned somewhat and we now confine this mod of therapy to highly selected patients. We hav not had experience with the use of phenol neurol ysis of peripheral nerve trunks, as advocated b Khalili and others, but have wondered whether th overall results may not be superior to and th procedure less time-consuming than the use o muscle motor point blocks.

Special Article

The Internist in Academic Medicine

ATHANASIOS THEOLOGIDES, M.D., Ph.D., F.A.C.P.

IN ALMOST ALL departments of medicine major changes have taken place in the medical curriculum, in the training for specialization, in the emphasis on research and in the interest and involvement in primary health care of the community. These changes affect the specialty of internal medicine and particularly the internist in academic medicine. There is a need for re-evaluation of his function as a clinician, teacher, and investigator.

In the last decade, there has been a remarkable change in the attitudes of the medical student toward learning. The student is no longer satisfied with a passive accumulation of information geared mainly to pass examinations and to score high on tests. He is interested in a medical curriculum relevant to the demands of the practice of medicine with an early and frequent contact with patients. He wants to master the process of learning medicine and of maturing clinically through an active participation in the planned teaching and through independent projects on free time.

These changes resulted in a shift of undergraduate medical teaching from the formal amphitheater lecture to bedside instruction and dialectic sessions in small groups. The academic internist is required to have significant competence in bedside clinical medicine. As a clinician with a good working knowledge in all areas of internal medicine coupled with a compassion for the patient he can initiate and guide the student in the establishment of rapport with the patient, in the procurement and analysis of clinical and laboratory data, their evaluation and synthesis for diagnosis, and finally in the process of management and therapy.

During the same period the philosophy of learning of the house staff has significantly changed. The house staff has developed the attitude of learning clinical medicine by assuming complete control of the diagnostic and the therapeutic management of the patient. Instead of proceeding under a close supervision and guidance by a faculty member they prefer to carry on the work-up and therapy independently and to call various faculty members to consult only on specific questions in their own subspecialty.

There is no doubt that today's intern and resident are better prepared, more mature clinically, and have more free time to look in the medical literature for help on diagnostic and therapeutic questions. However, it would be precarious to accept the resident as a seasoned internist capable of managing the patient without close supervision. Active guidance still represents an important aspect of the clinical training and the only way for the young physician to have the benefits of the experience of the mature clinician. But to exercise meaningful clinical supervision, the responsible faculty member has to gain the respect of the house staff for his knowledge, competence, and his ability to handle any problem in internal medicine at large. Expertness only in a limited area is not an adequate qualification for the role of the attending physician.

With a changing student, intern and resident there is a changing patient population in the teaching hospital. The increasing number of well-trained physicians and competent consultant-specialists in the community has decreased the need for the patient referral to the teaching hospital for the diagnosis and the management of the rare and complicated syndrome. On the other hand the proliferation of commercial laboratories for the unusual test has abolished the monopoly of a few investigators in teaching hospitals for the special test or the determination of a certain metabolite crucial for the diagnosis of a certain disease. The patient population of the teaching hospital resembles more and more the population of any private hospital with the exception of a greater number of patients with incurable diseases. Moreover, with the involvement of departments of medicine in primary health care the clinical teaching has to be done more and more on patients with conditions and diseases seen in

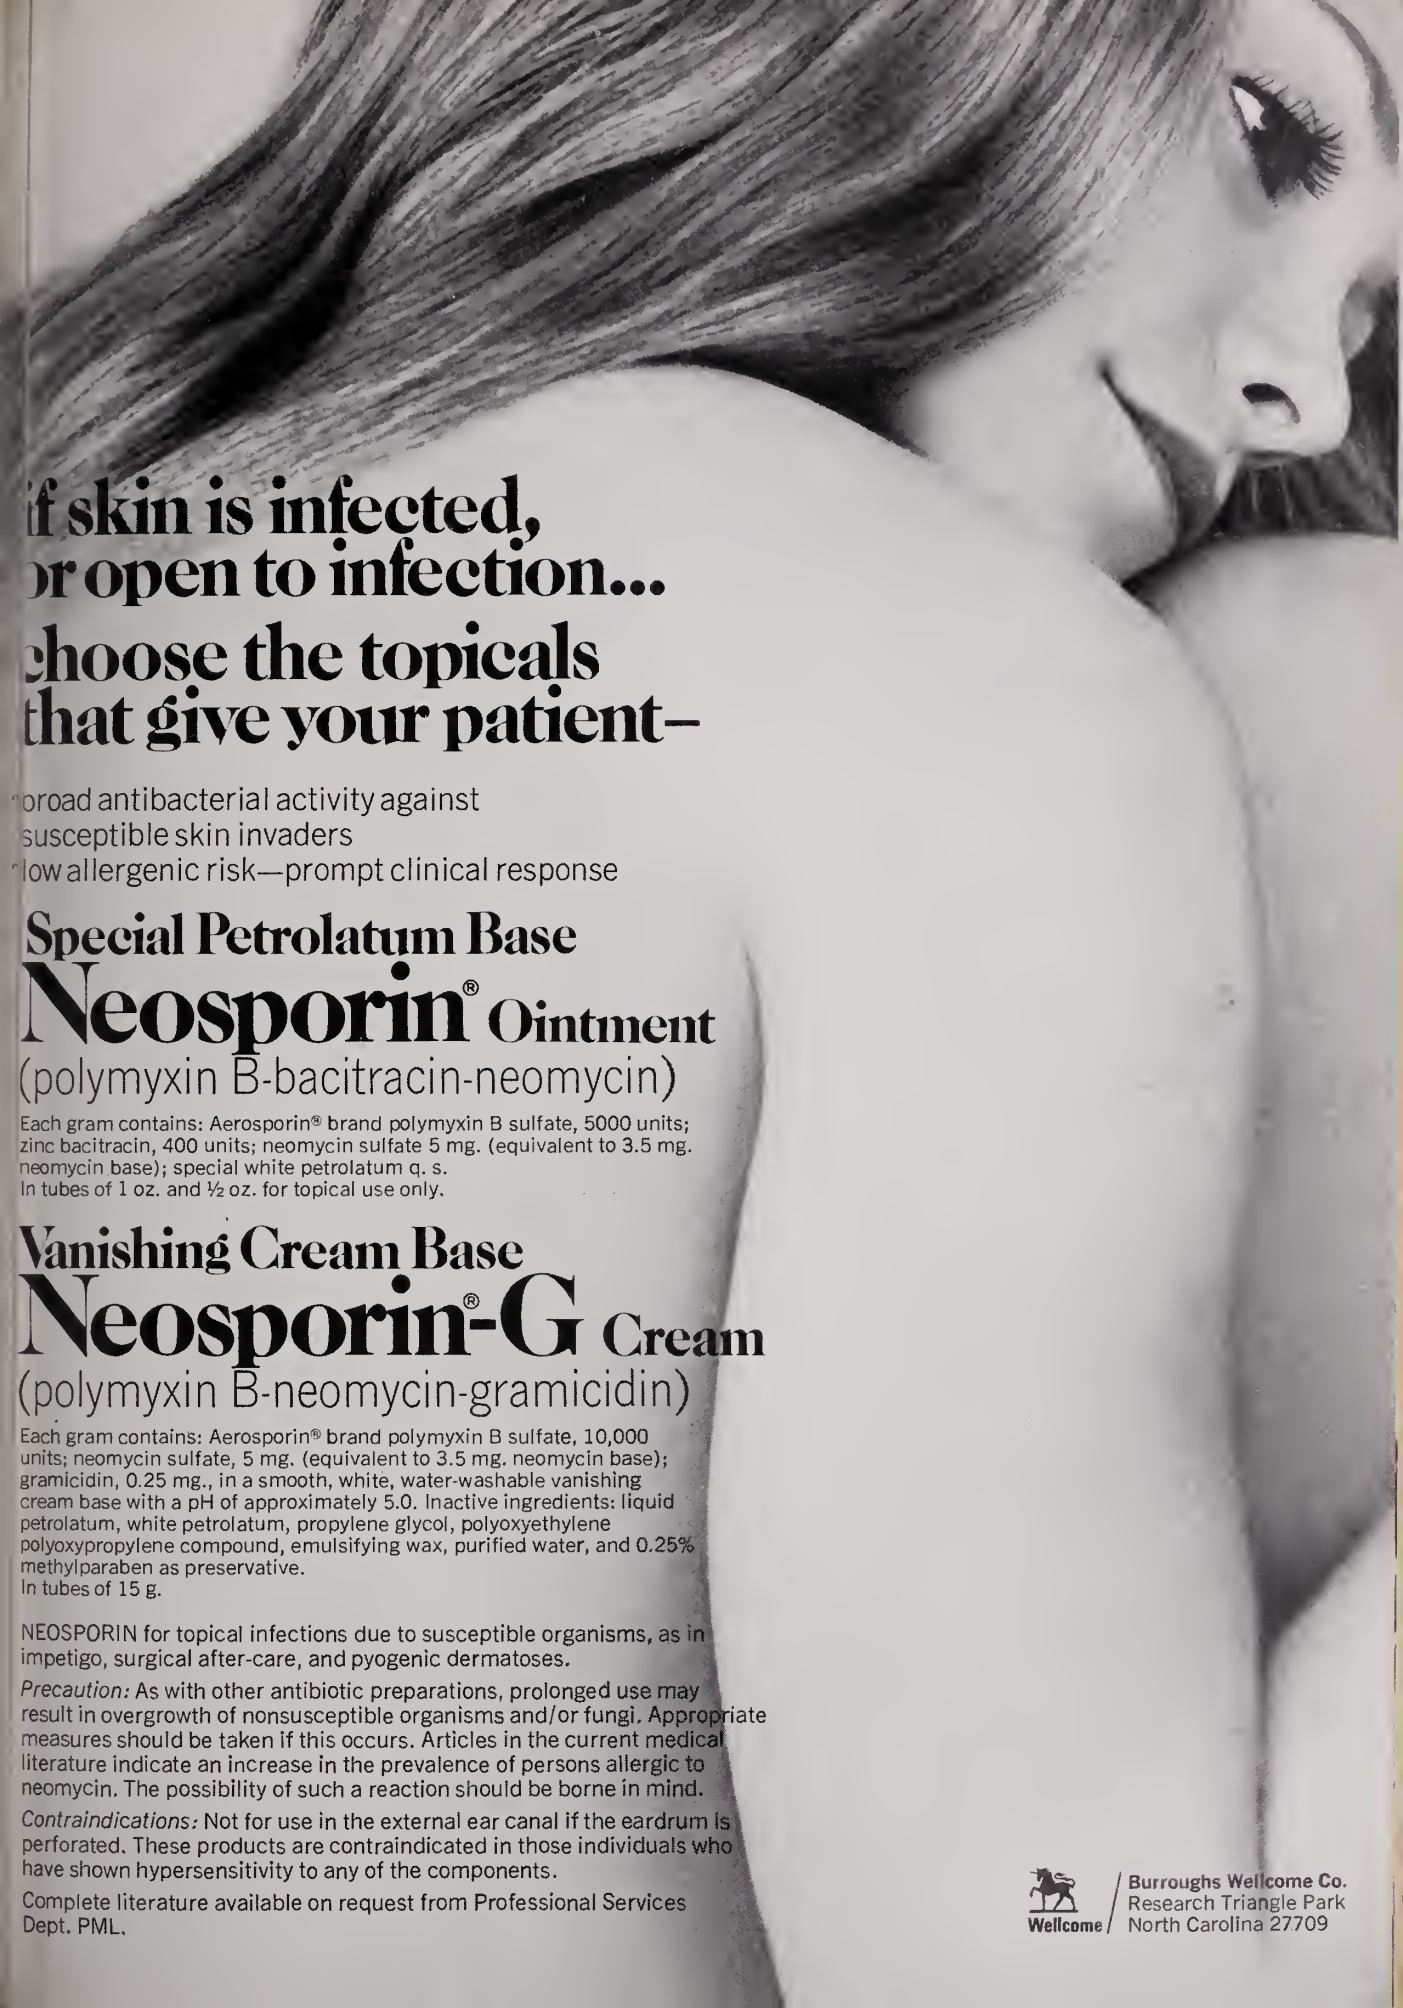
Dr. Theologides is an Associate Professor of Medicine, University of Minnesota Hospitals, Minneapolis, Minnesota.
See editorial, page 740.

the practice of medicine in the community and not on the patient with the rare syndrome.

All these changes emphasize the need in academic medicine of the well rounded internist with knowledge and clinical competence in all areas of internal medicine and not the narrow subspecialist with depth and research accomplishments only in a very limited region. The academic internist should be primarily an excellent clinician but who also has interest and competence in teaching and research.

The young physician who plans a career in academic medicine should have an intensive and broad training during residency and fellowship years and also frequent formal periodic retraining throughout his career in areas of internal medicine outside his own subspeciality. An area especially that should be emphasized is his education in the technique of teaching. It has been assumed that a good clinician is also a good teacher; but very often this is not the case. Therefore, instructions in teaching methods should be an added element in the training of the internist for academic medicine and periodic evaluation of his competence as a teacher should be stressed. During the formative years some administrative duties should be assigned to him for experience in problems and decision making in administration. Cours in personnel management would add a stron component to this experience.

Besides growing to be a competent clinician an teacher the young academic internist should als work to develop as an investigator. He shoul participate and later conduct independently clin cal, epidemiological or experimental research i an effort to find answers to bedside question In addition to contributing to the understandin and treatment of diseases, he can evaluate the re search contributions of basic research scientis and their applications to clinical medicine. B raising questions and trying to find answers he ca maintain an open inquiring mind to soften th absolutism of the pedagogue.



It appears therefore that with the changin world of patient care, student teaching, physicia training, and the need for more applied research the training programs for the development c academic internists should be re-evaluated. I these programs the new scientific and professiona requirements should be interwoven with the che ished old personal, cultural and social values c gentleness of feeling, concern and compassion fo the sick and the desirability of social commitmen

---

Psychiatry

I moved my lips—the Pilot shrieked
And fell down in a fit;
The holy Hermit raised his eyes,
And prayed where he did sit.
I took the oars: the Pilot's boy,
Who now doth crazy go,
Laughed loud and long, and all the while
His eyes went to and fro.
"Ha! ha!" quoth he, "full plain I see,
The Devil knows how to row."*

*Samuel Taylor Coleridge, "The Rime of the Ancient Mariner."

If skin is infected, or open to infection...

choose the topicals that give your patient–

- broad antibacterial activity against susceptible skin invaders
- low allergenic risk—prompt clinical response

Special Petrolatum Base
Neosporin® Ointment
(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

Vanishing Cream Base
Neosporin®-G Cream
(polymyxin B-neomycin-gramicidin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 10,000 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); gramicidin, 0.25 mg., in a smooth, white, water-washable vanishing cream base with a pH of approximately 5.0. Inactive ingredients: liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax, purified water, and 0.25% methylparaben as preservative.
In tubes of 15 g.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical after-care, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. These products are contraindicated in those individuals who have shown hypersensitivity to any of the components.

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

In usual IV doses, Lincocin (lincomyc hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water But when 4 grams or more per day is given, Lincocin should be diluted in n less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

infections caused by susceptible strains of pneumococci, streptococci, and staphylococci, including penicillin-resistant strains. Staphylococcal strains resistant to Lincocin (lincomycin hydrochloride, Upjohn) have been recovered. Before initiating therapy, culture and susceptibility studies should be performed. Lincocin has proved valuable in treating patients hypersensitive to penicillin or cephalosporins, since Lincocin does not share antigenicity with these compounds. However, hypersensitivity reactions have been reported, some of these in patients known to be sensitive to penicillin.

Well tolerated at infusion site: Lincocin intravenous infusions have not produced local irritation or phlebitis, when given as recommended. Lincocin is usually well tolerated in patients who are hypersensitive to other drugs. Nevertheless, Lincocin should be used cautiously in patients with asthma or significant allergies.

In patients with impaired renal function, the recommended dose of Lincocin should be reduced to 25—30% of the dose for patients with normal kidney function. Its safety in pregnant patients and in infants less than one month of age has not been established.

Lincocin may be used with other antimicrobial agents: Since Lincocin is stable over a wide pH range, it is suitable for incorporation in intravenous infusions; it also may be administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

© 72 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency trea e. *Skin and mucous membranes*—Skin he urticaria, vaginitis, and rare instances e foliative and vesiculobullous dermatit a been reported. *Liver*—Although no dir re lationship to liver dysfunction is estab he jaundice and abnormal liver functio es (particularly serum transaminase) hav ec observed in a few instances. *Cardiov* —Instances of hypotension following re teral administration have been rep e particularly after too rapid IV admi tr tion. Rare instances of cardiopulmon a rest have been reported after too ra l administration. If 4.0 grams or more a ni istered IV, dilute in 500 ml of flui ar administer no faster than 100 ml per *Special senses*—Tinnitus and vertigo av been reported occasionally. *Local rea* —Excellent local tolerance demonstra intramuscularly administered Lin c (lincomycin hydrochloride). Reports o pa following injection have been infre e Intravenous administration of Linco 250 to 500 ml of 5% glucose in d water or normal saline has produc n local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *5* Capsules—bottles of 24 and 100. *Solution, 300 mg per ml*—2 and 10 m and 2 ml syringe. *Syrup, 250 mg pe* —60 ml and pint bottles.

Violent Death and Alcohol Use

Among the Chippewa in Minnesota

JOSEPH WESTERMEYER, M.D., Ph.D. and JOHN BRANTNER, Ph.D.

N DOING CLINICAL work with Chippewa patients, stories of multiple traumatic events are com- only obtained. Moreover, in taking family his- ories with these patients, violent deaths appear to frequent. For example, among the first degree latives of thirty Chippewa alcoholics, 23 out of deaths (28.4%) occurred by accidents, homi- de, or suicide.

The literature demonstrates a high association etween violent death and alcohol use. Postmor- m examinations, done on single vehicle accidents New York, demonstrate that two-thirds of the talities have blood alcohol above 0.05%.[1] mong car accident casualties in New Zealand, ixty percent have blood alcohol of 0.10% or igher.[2] Using the case study method, over a hird of fatal accidents have been shown to in- olve chronic alcoholics.[3] Other violence also ears a strong relation to alcohol, as demonstrated y breathylyzer tests on victims of fights, assaults, nd home accidents in a Boston emergency room.[4]

Violent death may be common among Chip- ewa people. Among other groups of people iolent injuries or death are frequently associated with alcohol usage. We were therefore interested o see first, whether violent death is common mong Chippewa; second, whether violent death s associated with alcohol use among Chippewa; nd third, how the epidemiology of violent death mong Chippewa differs from the general popu- ation and other Indian groups.

Department of Psychiatry, University of Minnesota.

Method

Vital statistics for the state of Minnesota include "Indian" as a racial category. In the 1960 census, 95.4% of Minnesota Indians were estimated to be Chippewa. Thus, the category "Indian" in Minnesota virtually means Chippewa people.

Postmortem investigations are performed for all cases of violent death by the Hennepin County Medical Examiner. Investigation includes chart review, autopsy, police report, and—where indicated—analysis of blood or gastric contents for alcohol. Again, "Indian" is a racial category in these data. Based on information from the American Indian Employment Center in Minneapolis, between 80 and 90% of Indians in the area are Chippewa. As a result, detailed autopsies are available for those Chippewa people who die in the Minneapolis area.

Methodologically, data from urban Chippewa must be cautiously applied to the state-wide Chippewa population. Supportive information suggests that such a generalization can be reasonably made.

Data

Minnesota Vital Statistics

Violent Death Among Minnesota Indians. Violent deaths comprise the most common form of death among Minnesota Indian people during 1965-67 (Table 1). While one out of four Indian people die by such causes, only one out of twenty occurs in the general population. This category ranks fourth in the general Minnesota popu-

TABLE 1
Major Causes of Death
State of Minnesota
1965 - 1967

lation. Despite the relatively small number of Indians, the differences are highly significant ($P < .005$).

Hennepin County Medical Examiner

Violent Deaths, Hennepin County. During the years 1964-69 inclusive, 3305 violent deaths came to the attention of the medical examiner. Of these 41 (1.24%) were tabulated as Indian. Table 2 indicates the individual numbers for non-vehicular accident, vehicular accident, homicide, and suicide.

TABLE 2
Violent Deaths
Hennepin County Medical Examiner
1964 - 69

		Indian Deaths	
Cause of Death	Total Number of Deaths	Number	Percent of Total
Non-vehicular accident	1411	21	1.49%
Vehicular accident	1047	11	1.05%
Homicide	229	7	3.06%
Suicide	618	2	0.32%
Total	3305	41	1.24%

Non-vehicular Accidental Deaths. Of 21 Indian cases, 15 were judged to be alcohol related based on the medical investigation. Ages for all alcohol related deaths ranged from midteens to midfifties, while deaths not related to alcohol occurred in infancy or after the late fifties. Alcohol related causes of death included: falling (seven people), acute alcohol intoxication (three), carbon monoxide poisoning (three), and drowning (two).

A comparison was made between the Indian deaths (1964-69) and "all" deaths in 1969 (Table 3). A marked difference in mean age is not duc to the greater proportion of elderly peo in the "all" sample. By excluding all perso age 70 or older, the adjusted mean ages so c tained are similar. Sex ratios for both grou are similar.

Of those blood alcohol tests having positi results, the mean level of Indian tests is high than the "all" tests. Contributing to this diff ence are several cases of non-Indian people dyi of intoxication from alcohol plus other dru (barbiturates, amphetamines, analgesics). Into cation deaths among Indian people involve alcoh only.

Vehicular Accidental Deaths. Seven of t eleven Indian deaths were judged as alcoh related. In comparing Indian and "all" deat for age, sex, and blood alcohol, differences b tween the two groups are not significant.

Homicide Deaths. Of the seven homicide vi tims, four had elevated blood alcohol at the tir of death. Comparisons for age and sex do n demonstrate significant differences between t two groups. However an age disparity may b present: mean Indian age falls two decades behi the general population. Despite the few India in the sample, statistical testing for age do demonstrate a significant difference at the .0 level of probability (Table 4).

Suicide Deaths. One of the two Indian suicid was alcohol related. With so few Indian suicid

TABLE 3
Characteristics of Violent Death

ess than or equal to 25 years	7	12
ver 25 years	0	28

Fisher Exact $X^2_1 = 14.3, <P .005$

Blood Alcohol Tests. Blood alcohol tests offer fairly objective standard for comparison between ie two groups. Since the number in any one ubcategory of violent death is small, there is alue in grouping them together. As noted in able 1, the relative proportion of Indians to ie general population varies for each category. Iowever, the two largest categories, vehicular and onvehicular accidents, do not vary as widely as o the two smaller categories, homicides and uicide.

Blood specimen for alcohol content tend not o be taken from the very young or the very old. Among those who survive a long time posttrauma, in autopsy alcohol specimen is of no value. So lood alcohol specimens are reserved for persons vho may have recently taken alcohol. Comparing he Indian and "all" groups in Table 5, signifiantly more specimens have been taken from ndian persons at autopsy (at $P < .025$). Table 5 demonstrates that significantly more Indians have positive blood alcohol tests at autopsy relative to the general population ($P < .005$).

Discussion

Incidence of violent death among the Indian people of Minnesota is five times that of the general population. Based on data from Minneapolis, Indian violent death appears to be associated with alcohol to a significantly greater extent than in the general population.

TABLE 5
Comparison for Taking Blood Alcohol Specimens
Hennepin County Medical Examiner

Category	Indian deaths (1964-69)	All deaths (1969 only)
Specimen taken	26	269
Specimen not taken	15	331

$X^2_1 = 5.23, \ P < .025$

Despite these disparities between the two groups, notable similarities occur as well. Proportion of males and females does not vary significantly between Indians and the general population. Mean blood alcohol levels, taken from positive tests only, compare closely. Difference in mean alcohol level among nonvehicular accidental deaths appears related to the use of other drugs in the general population and the absence of such use among the Indian deaths.

Age distributions coincide only for the vehicular accident category. However, if persons aged 70 or older are excluded from nonvehicular accidents (few Indian people survive that long), then the two groups also compare closely for age. Only among homicide victims does there appear to be a significant age discrepancy, with Indian victims being significantly younger. Of interest here also is the relatively high rate of homicide victims in the Indian group.

These observations, the young age and high rate of Indian homicide victims in Minnesota, have been noted for Indian people in general in the United States.[5] Thus, the Minnesota Indian population, while unlike other Minnesotans in these regards, resembles other Indian people.

Minnesota Indian people appear to differ regarding suicide, however. Nationwide Indian statistics,[5] as well as work done by Dizmang and Resnick among tribal groups,[6-8] indicates quite a high rate of Indian suicide. One might wonder whether Indian suicide data from an urban area such as Minneapolis might be misleading or whether Chippewa people actually have less suicide.

Paredes[9] collected vital statistics from northern Minnesota, including Beltrami and Cass Counties where Chippewa reservations are located. His records cover 20 years (1940-64) and include homicide and suicide figures by race. Using the 1960 population for Cass and Beltrami Counties, the following crude homicide rates are obtained: 7.0 per 100,000 Indians per year, versus 1.3 per

TABLE 6
Comparison for Results of Blood Alcohol Specimens
Hennepin County Medical Examiner

Category	Indian deaths (1964-69)	All deaths (1969 only)
Alcohol present	23	118
No alcohol	3	151

$X^2_1 = 18.94, \ P < .005$

100,000 non-Indians per year. Again using the 1960 population as a denominator, crude suicide rates are: 6.1 per 100,000 Indians per year, and 10.7 per 100,000 non-Indians per year. Thus, for reservation areas, Chippewa homicide is much higher and Chippewa suicide is somewhat lower as compared to the general population. These rural data coincide with the urban statistics, both indicating a relatively low rate of Chippewa suicide and a relatively high rate of Chippewa homicide.

These differences in suicide rates among Minnesota Indians (mostly Chippewa) as compared to other Indian groups underscore an important point. While it is proper to look for trends and similarities among ethnic groups, it is an error in logic to assume conditions prevalent among one Indian tribal group will be present among another tribal group. The exceptions to general rules may provide clues.

There are no satisfactory explanations for the low rate of Chippewa suicides relative to the general Minnesota population and relative to other Indian groups. In fact prior clinical experience would have suggested a high rate. For example, 10 out of a series of 30 Chippewa alcoholics admitted to at least one suicide attempt, and several more reported suicidal preoccupation. In the last year at our institution, three Chippewa girls have gestured suicide by scratching or cutting their wrists during hospitalization. While one might logically argue that the "plea-for-help" gesture might inveigh against actual completed suicide among the Chippewa, we have no other data to support this contention.

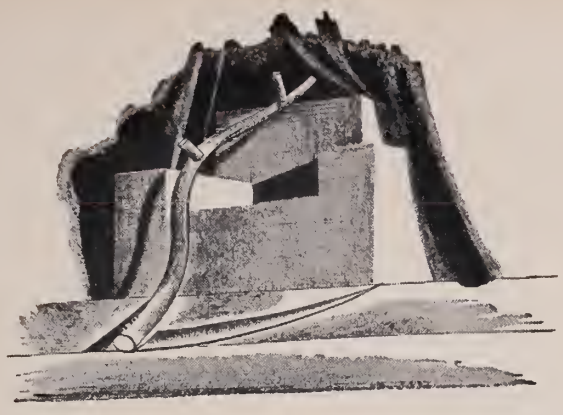
The question inevitably arises: Why so mu violent death among Minnesota Indians? In ad tion the exact nature of the alcohol-violence rel tionship is not clear. Is there more alcoholis among Indians in Minnesota? Do alcohol u and violence-seeking comprise a form of suicid or perhaps function as a depressive equivalen Or does risk-taking combined with alcohol u function as a mode of obtaining prestige? (relieving boredom?

Conclusions

Violent death occurs five times more oft among Indian people in Minnesota (most of who are Chippewa) than among the general popul tion. It is the most common cause of death f Indians in Minnesota during recent years.

In Minneapolis, violent deaths among India are significantly more often associated with alcoh use than in the general population.

In general, Chippewa victims of violent dea resemble such victims in the general populati with regard to sex, age, and blood alcohol lev A notable exception to this is homicide, whic occurs at an earlier age among Chippewa (as does among other American Indians). Homici occurs particularly often among Chippew whereas, unlike other Indian groups, suicide not so frequent.



Acknowledgement

Appreciation is expressed to Dr. Sidney Finklestein a Mr. Robert Hiller of the Minnesota State Department Health, Dr. John Coe of the Hennepin County Exam ner's Office, and Dr. Jacob Bearman of the Departme of Biometry at the University of Minnesota.

In Memoriam

Death is the golden key that opens the palace of eternity—Milton

IVAN T. CLARK, M.D.

Dr. Ivan T. Clark, 64, Sun City, Arizona, formerly of Duluth, died June 30. Born in Edgar, Nebraska, he graduated from Ohio State Medical School in 1941. A veteran of World War II, Dr. Clark went to Duluth in 1945 and moved to Sun City in the fall of 1970.

He was Chief of Radiology and former Chief of Staff at St. Mary's Hospital. Dr. Clark was a member of the St. Louis County Medical Society, the American Medical Association, the Minnesota State Medical Association and the Maricopa County, Arizona, Medical Society. He was a diplomate of the American Board of Radiology.

Dr. Clark is survived by his wife, Rosemary and two daughters, Mrs. Douglas Farnham and Mrs. Thomas King.

HENRY E. MICHELSON, M.D.

Dr. Henry Michelson, 83, a dermatologist, died May 10. He instituted the Dermatology Clinic at Hennepin County General Hospital, was Head of Clinic Service of the Division of Dermatology at the University of Minnesota Medical School, Professor and Director of the Division, emeritus professor following retirement in 1957 and consultant at Veterans Hospital and in postgraduate teaching at the Continuation Study Center.

Dr. Michelson was an examiner on the American Board of Dermatology, president of the Society of Investigative Dermatology, member of the editorial board of the AMA *Archives of Dermatology* and served as an editorial adviser for *The Journal Lancet*. He received the Outstanding Achievement Award of the University of Minnesota.

He was also a member of the Hennepin County Medical Society and the American Medical Association and 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by a son, Robert, and a daughter, Mrs. Scotson Webbe.

JOHN F. BRIGGS, M.D.

Dr. John F. Briggs, 67, St. Paul internist, died May 10. A native of St. Paul, Dr. Briggs had practiced there since the early thirties.

He was a past president of many medical organizations, including the American College of Chest Physicians, Minnesota Heart Association, Minnesota Thoracic Society and the St. Paul Society of Internal Medicine. He was an authority on both heart and lung diseases and served on many international, national, state and local medical committees relating to these ailments.

Dr. Briggs was a long-time chairman of the Minnesota State Medical Association's Committee on Pulmonary Diseases and its Heart Committee and served for many years as Public Relations Chairman for the Ramsey County Medical Society.

He was born in St. Paul, attended the University of Minnesota Medical School and interned at the Ancker Hospital.

There are no survivors.

PERCY A. MATTISON, M.D.

Dr. Percy A. Mattison, 69, Winona Urologist, died December 28, 1971. Born in Gardiner, New York, Dr. Mattison obtained his medical education at the University of Colorado Medical School in Denver.

He was a member of the Winona County Medical Society and the American Medical Association and an Associate Member of the Minnesota State Medical Association.

Dr. Mattison is survived by his wife, Mary.

HYMAN S. LIPPMAN, M.D.

Dr. Hyman S. Lippman, 76, St. Paul psychiatrist, died April 17. A former director of the Wilder Child Guidance Clinic, Dr. Lippman assisted in the development of a division of child psychiatry at St. Paul Ramsey Hospital.

Born in Minneapolis and educated at the University of Minnesota Medical School, Dr. Lippman spent 18 months in Vienna studying child and adult psychiatry. He was a member of the Ramsey County Medical Society, the American Medical Association and a 50 Club member of the Minnesota State Medical Association.

He is survived by his wife, Adelaide.

EDWARD M. LITIN, M.D.

Dr. Edward Litin, 51, Chairman Emeritus of the Department of Psychiatry at the Mayo Clinic, and an Associate Professor of Psychiatry at the University of Minnesota Graduate School, died April 28. He was born in Minneapolis and received his education at the University of Minnesota.

Dr. Litin was a past president of the American Psychiatric Association, a member of the Zumbro Valley Medical Society and the American Medical Association and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife, Lorraine, daughter Nancy Jo and a son, Scott, who is a medical student at Houston, Texas.

OWEN F. ROBBINS, M.D.

Dr. Owen F. Robbins, 65, a past chief of staff at St. Barnabas Hospital, died May 29. He was also a staff member of the Fairview-Southdale Hospital and a member of the American Board of Surgeons, Obstetricians and Gynecologists.

Dr. Robbins was a member of the Hennepin County Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Marjorie, two daughters, Mrs. Harold Pohlad and Mrs. Jan Ebert, and a son, Dr. Thomas O. Robbins of Detroit.

ARTHUR E. WALKER, M.D.

Dr. Arthur E. Walker, 68, St. Paul physician, died May 27. Born in Duluth, Dr. Walker obtained his medical education at Marquette University.

He was on the staffs of both St. Joseph's and Miller Hospitals and a member of the Ramsey County Medical Society and the American Medical Association and an Associate Member of the Minnesota State Medical Association.

Dr. Walker is survived by his wife, Esther, and tv sons, Curtis and Stuart.

JOSEPH D. SELMO, M.D.

Dr. Joseph D. Selmo, 61, Norwood surgeon, died M 11. He was born in Baltic, Michigan, and obtained h medical education at Loyola University School of Me cine in Chicago.

He was a member of the McLeod County Medic Society, the American Medical Association and t Minnesota State Medical Association.

Dr. Selmo is survived by his wife, Ruth.

MARVIN J. GEIB, M.D.

Dr. Marvin J. Geib, 59, Chief of Staff at St. Ansg Hospital in Fargo, died July 6. He was a founder of t Neuropsychiatric Institute in Fargo.

Born in Gaylord, Minnesota, Dr. Geib graduated fro the University of Minnesota Medical School in 193 He was a member of the Clay-Becker County Medic Society, the American Medical Association and the Mi nesota State Medical Association.

Neurological Grand Rounds

Temporal Lobe Seizures

RUSSELL B. BUTLER, M.D.

"And one of the multitude answered and said, 'Master, have brought unto thee my son, which hath a dumb irit. And wheresoever he taketh him, he teareth him; d he foameth and gnasheth with his teeth, and pineth ay. And I spake to thy disciples that they should cast n out; and they could not . . .'

"And they brought him unto Him; and when he saw m, straightway the spirit tare him, and he fell on the ound and wallowed foaming.

"And He asked his father, 'How long is it ago since is came unto him?' And, he said, 'Of a child. And oft nes it hath cast him into the fire, and into the waters, destroy him; but, if thou canst do anything, have mpassion on us and help us.'" Mark 9:17.

S IS EVIDENT from this quotation, man is known have had seizures since ancient times but, even ough the malady has been known for centuries, remains a source of awe and mystery even day. Hippocrates was among the first to recog- ze that epilepsy was somehow related to the rain. In the 19th century, Hughlings Jackson was ble to correlate certain areas of the brain with ecific epileptic manifestations. The mapping brain areas by sequence of symptoms during izures was done by Jackson and carries the onym "Jacksonian march."

In recent years, a reaction against Jackson's ethod of localizing seizures has arisen. Physicians ay see only the final expression of a seizure and ey should not infer that the area of abnormality necessarily localized to that part of the brain om which the clinical signs seem to be mani- sted. The seizure activity, seen clinically, may ll relatively little about where abnormal dis- harges arose. Yet, there is a type of seizure, the linical expression of which may indicate involve- ent of the temporal lobe.

Balaam was said to have "seen the vision, and ell into a trance, but with his eyes open" (Num- ers 24:4).[6] This may have been the first descrip- ion of temporal lobe epilepsy.

The symptom complex which eventually was ttributed to the temporal lobes was more ade- quately described in the 1870's by Saunders in Germany, and soon thereafter by Hamilton in he United States, and Anderson in England. Hughlings Jackson first correlated these symptoms with pathology in the temporal lobes of man. The symptoms that Jackson described in one case included olfactory and visual hallucinations, automatic movements, a dreamy state which had the feeling of "old scenes reverting" and the sensation of a "panorama of something familiar and yet strange," vertigo and gastric sensations, and temporary insanity. The patient was demonstrated to have a tumor at the extreme anterior end of the right temporosphenoidal ridge, involving the amygdaloid nucleus. Jackson later suggested the term "uncinate group of fits" to include these symptoms.[6]

The human temporal lobe has three phylogenically distinct areas, the rhinencephalon, the limbic system and the neocortex. Yakovlev referred to the same three areas respectively as the entopallium, the mesopallium, and the ectopallium.[25,27] These areas are not confined to the strict anatomical limits of the temporal lobe.

The most ancient phylogenetic area is the rhinencephalon or entopallium. This includes the olfactory-visceral forebrain and the amygdala. Functionally it is related to olfaction. In man this area is connected to the anterior hypothalamus and thereby with the parasympathetic system. It is also interconnected with the sympathetic nervous system by way of the posterior hypothalamus. The reticular activating system which subserves consciousness may also be connected to the rhinencephalon by way of the posterior hypothalamus. The entopallium, by its spontaneous activity or by interconnections, has an effect of cellular metabolism, circulation, movement of viscera, incretion, excretion and secretion. The tissue structure of this system is primitive, consisting of unmyelinated fibers with numerous interconnections and synapses.[25] Experimental stimulation of this system has produced masticatory movements, olfactory hallucinations and the loss of consciousness.[26]

The next area of the temporal cortex to develop phylogenically was Broca's limbic lobe, a part of the limbic system of Papez. This is the mesopallium described by Yakovlev and composed of the hippocampus which is believed to be important

From Neurological Service, Veterans Hospital, Minneapolis.

in memory and learning. There are interconnections through the hippocampal gyrus, the alveus and the fornix to the mammillary bodies, the anterior thalamus and cingulate gyrus. These areas appear to subserve sympathetic responses and conciousness. There are also interconnections with the orbital frontal areas and with the basal ganglia. The tissue is composed of more complex, longer fibers which are myelinated.[25] There have been several attempts to determine function by stimulation experiments, but no consistent results have been noted. Bilateral removal of this system, however, results in marked impairment of recent memory. Functionally, this is the area that may be construed as serving the outward expression of the internal state best exemplified by the "fight or flight" reflex, thirst, pain, fear, pleasure and other modalities of emotionality.[26]

The neocortical area of the temporal lobes (ectopallium of Yakovlev) is composed of the superior, middle, inferior and fusiform gyri.[27] These are directly connected to the frontal lobe by the uncinate fasciculus and to the occipital lobe via the inferior longitudinal fasciculus. Within this area of the dominant hemisphere is the transverse gyrus of Heschel which serves in the perception of auditory inputs. The cellular components of ectopallium are well myelinated and run in parallels through the nervous system.[25] Stimulation of this part of the temporal lobes may cause a variety of results. If Heschel's gyrus is stimulated, non-differentiated sounds or vertigo result. Occasionally stimulation more anterior to the gyrus of Heschel will cause more complex auditory hallucinations of voices, sounds or even music.[6,26] Visual hallucinations occur with stimulation of the posterior half of the temporal lobe. Occasionally visual illusions of micropsia or macropsia also occur. Fear and pleasure have resulted from stimulation of the anterior temporal pole.[26] Yakovlev considers this area to be the "sphere of effectation" which is able to affect the outside world by means of expression and work.[27]

The temporal lobes are connected widely to the sensory inputs of smell, hearing, vision, the viscera and the autonomic nervous system. Neurons carrying sensations converge within the posterior areas of the temporal lobe, become intermingled and then pass anteriorly. The anterior areas may serve an "executive" or "elaboration" function. Stimulation of the neocortex in the anterior parts of the temporal lobe will cause vivid and elaborate hallucinations of auditory, visual and visceral sensations.[21,25,26]

Clinical Manifestations

Hallucinations

These may be olfactory, gustatory, visceral, cephalic, visual, auditory or vestibular. The olfactory hallucinations are generally described as being unpleasant, and this hallucination as an isolated event is rare. Gustatory sensations are described as metallic, acid or bitter. Visceral hallucinations include nausea, abdominal distress, hunger, tachycardia, or the sensation of a full bladder. Cephalic hallucinations such as swelling, pressure or heat in the head may arise. Pure visual and auditory sensations may also occur.

Illusions

These are false precepts of existing stimuli and may be of visceral spatial-temporal nature or even of a visual nature. The spatial-temporal illusions may be manifested by the sensation of "deja vu" (the sensation of familiarity in a strange place) or "jamais vu" (the sensation of strangeness in a place that should be familiar). Macropsia or micropsia (as well as vertigo) may also occur.

Aphasia of Various Types

Aphasia after a seizure may be caused by exhaustion of the neurons after the prolonged stimulus of the seizure. Dysphasia, characterized by a speech automatism, with sterotype and repetition of words or by phrases of irrelevant content or context, may also occur.

Emotional Experiences

The emotional undertones of the temporal lobe seizure are characteristic of the disorder. Usually it is a further manifestation of the sensory hallucinations and illusions. The olfactory sensation may appear to be foul and even nauseating; the visceral sensations become strange and are, perhaps, associated with fear, rage or pleasure. Sexual experiences have been described.

Amnesia

Amnesia is one of the hallmarks of the temporal lobe seizure. There are two possible explanations. The anatomical localization of the hippocampus and the hippocampal gyrus in the temporal lobe may make these areas vulnerable to abnormal discharges and cause disruption of their memory function. Williams[25] advocated another concept: most of the symptoms of the psychomotor seizure are usually related to the personalization of the experience, or the "I am."

f this functioning is disrupted during the seizure, hen the inverse, or the "I am not" can be the symptom manifested. This would be expressed as amnesia for the event.

Automatisms

These are motor movements in association with the temporal lobe seizures. Possible interconnections with the motor cortex by way of synapses through the basal ganglia and the prefrontal cortex may account for the movements, which can be simple repetition such as smacking the lips or more complex ones which are repetitive and purposeless.

Disordered Behavior

The most complex and most debated symptom of the psychomotor seizure is that of disordered behavior. This is allegedly a manifestation of the automatisms, with an overplay of the emotions of rage or pleasure-seeking. Kluver and Bucy demonstrated that bilateral anterior temporal lobectomy in monkeys caused memory loss and passiveness. The correlation of psychopathic personality, mainly with temporal lobe foci, has been described in convicts with abnormal electroencephalograms.[8] Severe personality problems and antisocial behavior are felt to be more prevalent in patients with temporal lobe seizures.[23] There has also been considerable acceptance that types of "hyperkinetic impulsive behavior" may often be associated with abnormal electroencephalograms having temporal lobe foci.[16]

Sexual deviation has been described in association with damage to the temporal lobes.[11] In many of the instances of distorted personality and behavior the problem arises of determining if the entire personality is changed by the interictal disease as well as by the ictal state. There is reason to believe that some of the manifestations of the temporal lobe seizure may be continuous, and clinical only in that it is causing the patient to incorrectly perceive his environment. Hill[14] has suggested that the abnormal personality, the psychopathic aggression and antisocial behavior may be better correlated with abnormalities in the posterior part of the dominant temporal lobe. It is fallacious, however, to state that every person with temporal lobe seizures has a distortion of personality. Many well-adjusted and productive people are known to have the disease and live within the society.

Treatment

The treatment of the psychomotor seizure is difficult.[6] Celsus described epileptics of Rome drinking blood from fallen gladiators as a form of treatment. However, modern physicians use better medical measures; or surgery may be considered when medicines fail. About 11% of patients with temporal lobe seizures will have a poor response to medical therapy. Another 50% will have only a fair response to the medications now available.[15] Currently favored treatment of psychomotor seizures include: Dilantin (R), (diphenylhydantoin) Mysoline (R) (primidone) and Tegretol (R), (Carbamazepine). (The use of Tegretol for this disorder has not been approved by the Federal Drug Administration.) Often phenobarbital is added to the regimen. Mesantoin (R) (mephenytoin) and Phenurone (R) (phenaceamide) have also been used with varying success but are more toxic.

Anticonvulsants

The mechanisms whereby anticonvulsants work are slowly being elucidated.[14] Hydantoins may enhance extrusion of sodium from the cell, thereby hyper-polarizing the cell membrane; they may also reduce the ability of cells to respond to repeated tetanic stimuli, thereby preventing the spread of impulses.[15] The barbiturates and Mysoline (R) seem to be effective in preventing the depolarizing effect of acetylcholine at the synaptic junctions; perhaps they also stabilize the membrane by slowing the transport of sodium and potassium. The effect of repetitive discharges may be reduced.[15]

Anterior Temporal Lobectomy

Generally the anterior temporal lobe is removed back to the vein of Labbe, or about 5.5 to 8 cm from the temporal horn. The degree of success ranges from 43% to 53% in different series. The procedure is unilateral, as bilateral lobectomy causes severe memory loss and other undesirable effects. Some psychiatric disorders associated with the seizure disorder may improve. In about 45% of the patients with pre-existing psychiatric problems, improvement of their interpersonal relations followed. Others, including Meier,[18] have presented data based on the Minnesota Multiphasic Personality Inventory profiles and Psychopathological indices to suggest some decline in the schizo-adaptive behavior characteristics.

The complications of the surgical procedures have been visual field losses; occasionally, left-sided operations will result in dysphasia or even deficits in learning by auditory stimuli.

There was improvement in the electroencephalogram (EEG) in many of the cases, and the EEG has become one of the tools by which prognosis after the operation can be formulated. The surgical procedure usually includes the removel of the deeper structures, the uncus, amygdala and anterior hippocampus. The patients with removal of this area also seem to do better over the long run; those who had a rightsided EEG focus and subsequent removal of the right anterior temporal lobe do better than those with leftsided lesions[4] Mullan [20] has recommended ablation of the lateral nuclear mass of the thalamus and the ventral anterior subthalamic areas.

Temporal lobe seizures are most commonly seen in young adults; however, in 37% of one series,[2] symptoms could be traced back to before the age of 11 years. Another 35% of the patients had abnormalities such as social and verbal underdevelopment, enuresis or sleepwalking. A high incidence of birth trauma (51.3%) was reported in patients with psychomotor seizures.

Pathology

Sclerosis

As early as 1825, Bouchet and Cazauvieihl described sclerosis in the hippocampus of an epileptic patient. In 1880 Sommer gave his name to the area of pyramidal cells of hippocampus which had been noted to have degenerated in patients with "idiopathic" seizures. Since that time there have been several series composed of autopsy and post-surgical specimens from seizure patients with what is now called "Ammon's horn sclerosis." The cause, according to Earle, Baldwin and Penfield,[7] is herniation of the hippocampus into the tentorial opening during molding of the head at birth, which produces either direct pressure or arterial compression with anoxia and which may cause scaring to the temporal lobe tip. Other workers have reported that closed intracranial injuries, encephalitis, or chronic sinusitis[26] may produce damage to the same area.

Atrophy

About 40 to 50 percent of patients with temporal lobe seizures have atrophy of the inferior and medial aspects of the temporal lobe. According to Meyer [19] the lesions in the temporal lobe may show subpial or marginal gliosis in which glial tissue is increased in the first cortical layer, along with nerve cell loss, and subcortical gliosis, in which there is a proliferation of astrocytes and the loss of axones in the white matter.

Neoplasms

About 12 to 18 percent of cases show neoplasms in association with the seizure disorder. The patients with classical uncinate fits have a higher incidence of low-grade gliomas. About 5% or less are associated with vascular malformations. About 20% have no demonstrable lesion.

Electroencephalogram (EEG)

Gibbs, Gibbs and Fuster[13] were among the first to correlate the EEG with temporal lobe seizures. About 95% of the patients studied at the Montreal Neurological Institute had an abnormal EEG which correlated well with their clinical symptoms. Of these, 80% had foci in the anterior-inferior-medial temporal areas and 15% had discharges seen in the posterior or middle temporal areas. Hill[14] described an EEG pattern which is present in 46% of the patients with temporal seizures: an initial generalized voltage suppression followed by generalized rhythmical slow-waves which progressively increase in amplitude and decline in frequency, followed by abrupt onset of generalized flattening for several minutes. The record then returns to a normal inter-ictal pattern. Gastaut[12] states that as many as 25% of patients will show no characteristic changes on EEG. Woolsey[26] noted that active seizure discharges deep in the anterior medial temporal lobe may have no electrical counterpart on the cortical or scalp electrodes. This may account for Gastaut's observation.

Comments

The current problems with drug abuse has added interest and concern to the problems of the temporal lobe seizures. There have been postulations that compounds such as Lysergic Acid Diethylamide (LSD-25), Psilocybin and Psilocin may be causing a form of temporal lobe seizures.[1] Demonstrations with cats have shown that LSD-25 administration results in seizure activity recorded with implanted electrodes in the amygdala, entorhinal cortex and parts of the hippocampus. There is further evidence that these three compounds have their effect by means of the temporal lobes since the temporal lobes have to be intact to produce clinical symptoms, as it has been demonstrated that LSD-25 will not have an affect in chimpanzees who have had bitemporal lobectomies.[3]

Classified Advertisements

Classified advertising rates are thirty (30) cents a word; minimum monthly charge $7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

CLINICAL DIRECTOR to administer the medical aspects of a progressive 1,200 resident facility for the mentally retarded. Will be responsible to the Superintendent for all aspects of the clinical service and supervision of staff. Specialists in pediatrics, neurology or internal medicine will be preferred. Board certification is desirable. Eligibility for Michigan licensure required. Salary ranges from $29,211 to $36,372 with starting salary dependent on qualifications. Housing currently available at nominal cost. Excellent fringe benefit and retirement program through Michigan's outstanding Civil Service. The facility is located in a small, progressive community in lower Michigan which provides a style of life many would like to recapture yet it is close enough to cities such as Saginaw, Flint and Detroit to provide the shopping, entertainment and cultural life of the big city. To apply send vitae to the Superintendent, Caro State Home and Training School, Caro, Michigan 48723.
AN EQUAL OPPORTUNITY EMPLOYER

BAYPORT, MINNESOTA—Ideal location for general practitioner. Partially equipped office, two blocks from St. Croix River. Fully accredited hospital three miles away. Site of Andersen Corp., largest wood window manufacturer employing 1600. Retired physician practiced 48 years in Bayport. Physicians in nearby community will backup physician for any vacation time or attendance at meetings, etc. Excellent potential for one or two physicians. Contact: Keith R. Clements (612) 439-5195.

GENERAL PRACTITIONER—County seat community of 2000. Modern 35 bed hospital 4 blocks from fully equipped clinic. Present associate retiring January 1, 1973. Early partnership. Contact H. A. Knoche, M.D., Gaylord, Minnesota 55334. Telephone 612-237-2528.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

Book Reviews

UNDERSTANDING LABORATORY MEDICINE, Camillo V. Bologna, M.D. C. V. Mosby Co., St. Louis, 1971, 259 pages. $9.80.

Written by the Director of Laboratories of St. Ansgar Hospital of Moorhead, and St. Francis Hospital of Breckenridge, Minnesota, this book is geared primarily for paramedical individuals and for physicians desirous of some conceptual understanding of laboratory medicine. Though the volume is geared for the professional, the level of approach is often too elementary. While the title purports to convey an understanding of the broad field of laboratory medicine, the contents touch only very superficially on the areas of blood banking, genetics, microbiology, and serology-immunology. It is possible that the author has responded less to these areas of laboratory medicine because the questions and discussions which he relates provided the stimulus for this volume were not forthcoming in these disciplines.

The author's conceptual approach to his topic is an interesting one. The chapters proceed from the normal cell and its milieu to "the cell community as a body," at the same time embracing some physiology, biochemistry, pathology and philosophy. Electrolyte, acid-base and fluid balance are then discussed. Subsequently he deals with bone, muscle and very briefly protein. At this point one has covered one-third of the volume. Chapters then deal with the circulatory system, hematology, liver disease, a lengthy chapter on hormones, and a brief discussion of enzymes of clinical importance. The role of man in the biosphere is interposed between the cellular fluid milieu and the discussion of mesodermal structures.

Although the author states that he does not wish to go into methodology, some discussion of the specimens used, and specimen collection, subjects much misunderstood in laboratory medicine, would have been very useful to the individuals for whom this book was written.

The reviewers would also challenge certain points made by the author. Among these, and for example, we believe that urinary urobilinogen is *increased* in hemolytic disease and *decreased* in extrahepatic obstruction. We also doubt that 2% acetic acid will dissolve yeast as well as red blood cells.

INTRODUCTION TO HEMATOLOGY by William M. Dougherty, C. V. Mosby. $10.50.

The author states that this is an introductory book designed for the beginning student and written to promote understanding without necessity for rote memorization. Although he has covered a large volume of material with a concise text, I do not think that it promotes an easy understanding of the subject of hematology. He eliminates the discussion of a number of items which should be present in an introductory hematologic text and which the beginning student could not be expected to know without some prior exposure to hematology and hematologic laboratory techniques.

The illustrations are black and white photographs, many of which have poor definition. In introducing a person to the identification of blood cells, a small number of good colored photographs is superior to an over-abundance of black and white photographs. The legends explaining the illustrations are cumbersome, often placed on pages removed from the figure which they are describing and are too lengthy.

I recommend this book review for the physician or paramedical person who has a background in hematology but who wishes to bring himself up to date with current changes. However the author includes little comparison of current terminology with prior definitions changed within recent years.

St. Louis Park, Minnesota

FORUM. The International Journal of Human Relations. Vol I, No. 4 January 1972. London.

Forum Volume 1 Number 4 is the January, 1972 issue of a new journal of uncertain age. Volume I suggests a new journal, but the inside front cover consists of an advertisement for back numbers at $1.00 each for issues of Volumes 2, 3, and 4. Forum seems to be London's answer to the U.S.A.'s publication "Medical Aspects of Human Sexuality," a collector's item which has appeared unsolicited on my desk since 1967. One title of the table of contents should suffice to establish the titillating quality and character of Forum: Learning to last—ejaculation control techniques. If Forum were illustrated it would rate a Hollywood X. A proper review would lead the printer to mail MINNESOTA MEDICINE in a plain wrapper.

Reuben Berman, M.D.
Minneapolis, Minnesota

DRUGS OF CHOICE by Walter Mondell. C. V. Mosby Co., St. Louis, publisher, $17.75, about 900 pages.

This is a well-prepared book, each of the 41 chapters dealing with a more or less specific entity and a choice of medication that can be used.

There is a Drug Index and a Generic Index, which by the process of cross reference makes it possible to be used either from the tradename or the generic name, as a useful reference book. It has been well-edited, beautifully printed and excellently bound.

Request for Physican's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers has received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Because of limitation of space, pictures oriented horizontally are preferred. All pictures will be returned if identified with the name and address of the physician. Please submit your pictures as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

AVAILABLE FOR immediate occupancy in the Signal Hills Shopping Center in West St. Paul —medical suite consisting of reception room, office and examination rooms. Call Mr. Asfeld or Mr. Callahan at 222-7471.

PSYCHIATRIC RESIDENCIES—Excellent, approved psychiatric education; intellectually demanding and clinically diversified in a stimulating, well-balanced program. Affiliated with Michigan State University's College of Human Medicine. The setting is in a culturally rich community; the serene, scenic Grand Traverse Bay area. Three year plan: $12,820 to $14,574; Five year plan: $14,637 to $27,436. Contact Dr. Paul E. Kauffman, Director of Psychiatric Training, Room 166, Traverse City Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

GENERAL PRACTITIONER—Excellent location in the Lost Pines of Texas area, growing community of 3,500 along the beautiful Colorado River. Has an excellent opportunity for a good family General Practitioner. Excellent small hospital (25 beds) and Nursing Home (65 beds) complex, guaranteed salary if desired, clinic, ancillary services and other fringe benefits will make this difficult to turn down if interested in working in a progressive rural community only 40 miles from a metropolitan area. Smithville Hospital Authority; Irvin Row, Administrator, Box 89, Smithville, Texas 78957. AC 512, 237-2441.

INTERNISTS and family physicians badly needed in Atlanta suburb near third busiest airport in world. New offices available adjacent to new 385 bed South Fulton community hospital. Please contact: Mr. Jim Henderson, Lee-Dixon Realty, Inc., 5075 Old National Highway, Atlanta, Georgia 30349, Phone: 404-762-8175.

3 EMERGENCY ROOM Physicians wanted to staff new E.R. facilities of 200 Bed Hospital. 50 man multispecialty Clinic physically adjacent provides immediate consultation and support. No pediatric responsibility. Michigan Resort City on Lake Michigan. Salary negotiable. Many fringe benefits. Reply to: John Rasmussen, Administrator, Burns Clinic Medical Center, P.C., Petoskey, Michigan 49770.

SEPTEMBER, 1972

The negative power of clinically significant anxiety in angina pectoris...
This man feels he is living on borrowed time.

During anginal attacks, patients may suffer intense apprehension. More frequently, however, they experience a continuing sense of less severe but nonetheless disproportionate anxiety.

Reduction of such clinically significant anxiety is important, since undue emotional stress may precipitate further anginal episodes.

djunctive Librium (chlordiazepoxide HCl) may be pecially suitable for relief of clinically significant xiety and emotional tension in anginal patients cause of its generally prompt therapeutic effectiveness and wide margin of safety. In a recent double-blind ndomized study,* Librium (chlordiazepoxide HCl) as administered for relief of moderate anxiety in 20 ginal patients seen in office practice over a 20-week riod. Symptoms of emotional distress related to xiety were rated at base-line, one week, two weeks d monthly thereafter. Relief was obtained notably rly in therapy. The clinical results demonstrated that ibrium offers the coronary patient an antianxiety drug at, in the author's opinion, is both effective and safe. general use, the most common side effects reported ve been drowsiness, ataxia and confusion, rticularly in the elderly and debilitated. (See mmary of prescribing information.)

ibrium (chlordiazepoxide HCl) is used concomitantly ith certain specific medications of other classes of rugs, such as cardiac glycosides, diuretics and antihyertensive agents, whenever anxiety is clinically signifint. The drug should be discontinued after anxiety has en reduced to appropriate levels.

The positive power of adjunctive Librium® (chlordiazepoxide HCl)

10-mg, 25-mg capsules up to 100 mg daily

for moderate to severe anxiety ccompanying angina pectoris

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

May 1957

The age of semi-synthetic penicillins begins at Beecham Research Laboratories.

The crucial experiment: conversion of 6-aminopenicillanic acid (6-APA) into benzylpenicillin by treatment with phenylacetyl chloride. We've come a long way since 1957. Over the past 14 years more than 3000 different semi-synthetic penicillins have been synthesized and evaluated by our staff. The fruits of their work are in your hands today.

The Advertising Pays for Your Journal

Why send him to the islets of Langerhans?

Since sulfonylureas promote the release of insulin which is lipogenic and helps transport glucose into adipose tissue...

And since many overweight patients already have normal or high levels of endogenous insulin, why not consider DBI-TD?

It lowers blood sugar without stimulating insulin secretion from the pancreas. And this may be important to the dieting diabetic.

In adult-onset, nonketotic diabetics uncontrolled by diet alone...

DBI-TD® phenformin HCl **Geigy**

lowers blood sugar without raising blood insulin.

I® phenformin HCl
lets of 25 mg.
I-TD® phenformin HCl
ed-Disintegration
sules of 50 and 100 mg.

ications: Stable adult diabetes litus; sulfonylurea failures, nary and secondary; adjunct to lin therapy of unstable diabetes litus.

traindications: Diabetes mellitus t can be regulated by diet alone; enile diabetes meliitus that is omplicated and well regulated on lin; acute complications of betes mellitus (metabolic acidosis, a, infection, gangrene); during mmediately after surgery where lin is indispensable; severe atic disease; renal disease with mia; cardiovascular collapse ock); after disease states ociated with hypoxemia.

Warnings: Use during pregnancy is to be avoided.

Precautions: 1. *Starvation Ketosis:* This must be differentiated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of relatively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state. **Do not give insulin without first checking blood and urine sugar.**

2. *Lactic Acidosis:* This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.

3. *Hypoglycemia:* Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.

Adverse Reactions: Principally gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake.

(B) 98-146-103-D (6/72)

DBI 8666

a new outlook in chronic pain

of moderate to severe intensity

Though Talwin® Tablets, brand of pentazocine (as hydrochloride), can be compared to codeine in analgesic efficacy, Talwin is not subject to narcotic controls. Patients receiving Talwin Tablets for prolonged periods face fewer of the consequences you've come to expect with meperidine or codeine. And that, in the long run, can mean a better outlook for your chronic-pain patient.

Talwin Tablets are:

- **Comparable to codeine in analgesic efficacy:** one 50 mg. Talwin Tablet appears equivalent in analgesic effect to 60 mg. (1 gr.) of codeine. Onset of significant analgesia usually occurs within 15 to 30 minutes. Analgesia is usually maintained for 3 hours or longer.
- **Tolerance not a problem:** tolerance to the analgesic effect of Talwin Tablets has not been reported, and no significant changes in clinical laboratory parameters attributable to the drug have been reported.
- **Dependence rarely a problem:** during three years of wide clinical use, only a few cases of dependence have been reported. In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.
- **Not subject to narcotic controls:** convenient to prescribe – day or night – even by phone.
- **Generally well tolerated by most patients:** infrequently cause decrease in blood pressure or tachycardia; rarely cause respiratory depression or urinary retention; seldom cause diarrhea or constipation. If dizziness, lightheadedness, nausea or vomiting are encountered, these effects tend to be self-limiting and to decrease after the first few doses. (See last page of this advertisement for a complete discussion of adverse reactions and a brief discussion of other Prescribing Information.)

50 mg. Tablets

Talwin®

brand of

pentazocine (as hydrochloride)

the long-range analgesic

a new outlook in chronic pain

of moderate to severe intensity

Contraindications: Talwin, brand of pentazocine (as hydrochloride), should not be administered to patients who are hypersensitive to it.

Warnings: *Head Injury and Increased Intracranial Pressure.* The respiratory depressant effects of Talwin and its potential for elevating cerebrospinal fluid pressure may be markedly exaggerated in the presence of head injury, other intracranial lesions, or a preexisting increase in intracranial pressure. Furthermore, Talwin can produce effects which may obscure the clinical course of patients with head injuries. In such patients, Talwin must be used with extreme caution and only if its use is deemed essential.

Usage in Pregnancy. Safe use of Talwin during pregnancy (other than labor) has not been established. Animal reproduction studies have not demonstrated teratogenic or embryotoxic effects. However, Talwin should be administered to pregnant patients (other than labor) only when, in the judgment of the physician, the potential benefits outweigh the possible hazards. Patients receiving Talwin during labor have experienced no adverse effects other than those that occur with commonly used analgesics. Talwin should be used with caution in women delivering premature infants.

Drug Dependence. There have been instances of psychological and physical dependence on parenteral Talwin in patients with a history of drug abuse and, rarely, in patients without such a history. Abrupt discontinuance following the extended use of parenteral Talwin has resulted in withdrawal symptoms. There have been a few reports of dependence and of withdrawal symptoms with orally administered Talwin. Patients with a history of drug dependence should be under close supervision while receiving Talwin orally.

In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.

Acute CNS Manifestations. Patients receiving therapeutic doses of Talwin have experienced, in rare instances, hallucinations (usually visual), disorientation, and confusion which have cleared spontaneously within a period of hours. The mechanism of this reaction is not known. Such patients should be very closely observed and vital signs checked. If the drug is reinstituted it should be done with caution since the acute CNS manifestations may recur.

Usage in Children. Because clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Ambulatory Patients. Since sedation, dizziness, and occasional euphoria have been noted, ambulatory patients should be warned not to operate machinery, drive cars, or unnecessarily expose themselves to hazards.

Precautions: *Certain Respiratory Conditions.* Although respiratory depression has rarely been reported after oral administration of Talwin, the drug should be administered with caution to patients with respiratory depression from any cause, severe bronchial asthma and other obstructive respiratory conditions, or cyanosis.

Impaired Renal or Hepatic Function. Decreased metabolism of the drug by the liver in extensive liver disease may predispose to accentuation of side effects. Although laboratory tests have not indicated that Talwin causes or increases renal or hepatic impairment, the drug should be administered with caution to patients with such impairment.

Myocardial Infarction. As with all drugs, Talwin should be used with caution in patients with myocardial infarction who have nausea or vomiting.

Biliary Surgery. Until further experience is gained with the effects of Talwin on the sphincter of Oddi, the drug should be used with caution in patients about to undergo surgery of the biliary tract.

Patients Receiving Narcotics. Talwin is a mild narcotic antagonist. Some patients previously receiving narcotics have experienced withdrawal symptoms after receiving Talwin.

CNS Effect. Caution should be used when Talwin is administered to patients prone to seizures; seizures have occurred in a few of patients in association with the use of Talwin although no causal effect relationship has been established.

Adverse Reactions: Reactions reported after oral administration of Talwin include *gastrointestinal:* nausea, vomiting; infrequently constipation; and rarely abdominal distress, anorexia, diarrhea. *CNS effects:* dizziness, lightheadedness, sedation, euphoria, headache; infrequently weakness, disturbed dreams, insomnia, syncope, visual blurring and focusing difficulty, hallucinations (see *Acute CNS Manifestations* under WARNINGS); and rarely tremor, irritability, excitement, tinnitus. *Autonomic:* sweating; infrequently flushing; and rarely chills. *Allergic:* infrequently rash; and rarely urticaria, edema of the face. *Cardiovascular:* infrequently decrease in blood pressure, tachycardia. *Other:* rarely respiratory depression, urinary retention.

Dosage and Administration: *Adults.* The usual initial adult dose is 1 tablet (50 mg.) every three or four hours. This may be increased to 2 tablets (100 mg.) when needed. Total daily dosage should not exceed 600 mg.

When antiinflammatory or antipyretic effects are desired in addition to analgesia, aspirin can be administered concomitantly with Talwin.

Children Under 12 Years of Age. Since clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Duration of Therapy. Patients with chronic pain who have received Talwin orally for prolonged periods have not experienced withdrawal symptoms even when administration was abruptly discontinued (see WARNINGS). No tolerance to the analgesic effect has been observed. Laboratory tests of blood and urine and of liver and kidney function have revealed no significant abnormalities after prolonged administration of Talwin.

Overdosage: *Manifestations.* Clinical experience with Talwin overdosage has been insufficient to define the signs of this condition.

Treatment. Oxygen, intravenous fluids, vasopressors, and other supportive measures should be employed as indicated. Assisted or controlled ventilation should also be considered. Although nalorphine and levallorphan are *not* effective antidotes for respiratory depression due to overdosage or unusual sensitivity to Talwin, parenteral naloxone (Narcan®, available through Endo Laboratories) is a specific and effective antagonist. If naloxone is not available, parenteral administration of the analeptic, methylphenidate (Ritalin®) may be of value if respiratory depression occurs.

Talwin is not subject to narcotic controls.

How Supplied: Tablets, peach color, scored. Each tablet contains Talwin (brand of pentazocine) as hydrochloride equivalent to 50 mg. base. Bottles of 100.

President's Letter

Minnesota Physiatric Society

The Minnesota Physiatric Society is pleased to be included in the list of organizations now represented by Minnesota Medicine. The term "physiatric" may be new to some. It refers to the Physiatrist, a physician who practices the specialty of Physical Medicine and Rehabilitation. Although the Minnesota Physiatric Society is quite young (founded in 1964) the specialty itself is not so new. The American Board of Physical Medicine and Rehabilitation was established under the Advisory Board of Medical Specialties in 1947 and the first Board examinations were conducted in Minneapolis that year.

Before the late 1950s many thought of this specialty as being mainly involved with poliomyelitis. Since that disease has been virtually eliminated, Physiatry has become better known for its work with such patient problems as spinal cord injury, strokes, amputations, joint disorders, and many of the degenerative disorders of the neuro-musculo-skeletal systems. Physical Medicine and Rehabilitation as a specialty has been involved in the application of physical sciences to medicine; for example, microwave (radar), ultrasound, and the use of electronics in the diagnosis of nerve and muscle disorders known as electromyography and electroneuronography. It has widely broadened the understanding and therapeutic application of the physiology of muscle and physiology of exercise.

Minnesota physiatrists have played a prominent role in the development of Physical Medicine and Rehabilitation as a medical specialty. Dr. Frederic J. Kottke, Professor and Head of the Department of Physical Medicine and Rehabilitation at the University of Minnesota, served on the American Board of Physical Medicine and Rehabilitation from 1955 to 1969. Dr. Frank H. Krusen, Founder of the Section on Physical Medicine and Rehabilitation of the Mayo Clinic, played a leading role in establishing the present Section of Physical Medicine and Rehabilitation in the American Medical Association. Dr. Glenn Gullickson, Director of the Rehabilitation Center, University of Minnesota Hospitals, served as the Executive Director of the American Congress of Physical Medicine and Rehabilitation from 1960 to 1965. Dr. Paul Nelson, Cleveland, Ohio, Editor of the Archives of Physical Medicine and Rehabilitation, has served as the Editor of the Archives since 1953. He is a native of Minnesota, having received his medical schooling and specialty training at the University of Minnesota and the Mayo Foundation. The Handbook of Physical Medicine and Rehabilitation is authored by three prominent Minnesota physiatrists; Drs. Krusen, Kottke and Ellwood. Dr. Miland Knapp, the pioneer in this field for Minnesota as well as a leader in national organizations, has for the past decade participated in an unusual program of continuing education for physicians in rural and small communities.

For many years the state of Minnesota has had the highest proportion of board certified physiatrists per capita of any state in the U.S.A. The Minnesota Physiatric Society now has 48 members. Most of these physiatrists are concentrated in the Twin Cities and Rochester.

"The history of science, and in particular the history of medicine...is... the history of man's reactions to the truth, the history of the gradual revelation of truth, the history of the gradual liberation of our minds from darkness and prejudice."

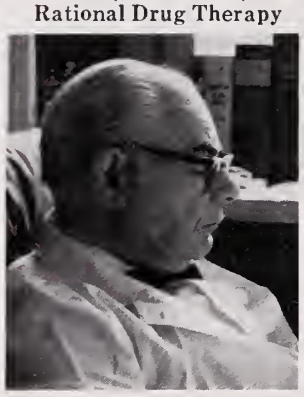
—George Sarton, from "The History of Medicine Versus the History of Art"

Would it be useful in clinical practice to have government predetermine drugs of choice?

Opinion

Results of a survey of physicians:

13.3%
Yes, it would be useful.



86.7%
No, it would not be useful.

Dialogue

Would it be useful in clinical practice to have government predetermine drugs of choice?

Doctor of Medicine

Walter Modell, M.D.,
Professor of Pharmacology,
Cornell University
Medical College,
Editor,
Clinical Pharmacology
& Therapeutics,
Drugs of Choice,
Rational Drug Therapy

The proposition that government should determine one or two "drugs of choice" within a given therapeutic class reflects the belief that a similarity in molecular structure insures a close similarity in pharmacologic effect. But this is by no means the rule. An obvious example would be in the field of diuretics, where a small change in chemical structure accounts for substantial differences in concomitant effects such as potassium excretion.

Any attempt to dictate the "drug of choice" would be complicated by the fact that some populations demonstrate a bimodal distribution in their reaction to drugs. If the data on drug response are mixed for the total population, one drug will appear to be as useful as the other. But if drug response is reported separately for different segments of the population, drug A will be found to be better for one group and drug B for the other.

It may, of course, be possible to determine drugs of choice in particular categories on a broad statistical basis. But there are always certain patients in whom a drug produces odd, unpredictable or idiosyncratic reactions. So, though a drug might statistically be the most useful one in a given situation, individual variations in response might make it the *incorrect* one.

The point I wish to make is that if two, three, four or more drugs in one class are of approximately equal merit, that in itself is justification for their availability. Exceptional cases do arise in which one drug would be useful to a certain segment of the population and another drug would be of no use at all. In the practice of medicine, the physician must be prepared to treat the routine as well as the unusual case.

Another objection to the determination of a drug of choice is that precise statements of *relative* efficacy are very difficult to make—much more difficult than statements of efficacy. For example, in testing drug efficacy, it is easy to determine the difference between a drug that is effective in treating a condition and one that is not at all effective. Thus, it is fairly easy to determine whether a drug is more effective than a placebo. But if you compare one drug that is effective with another drug that is also effective, and the relative differences between them are very slight, statements of relative efficacy may be very difficult to make with assurance.

I do not mean to imply that relative efficacy statements are not useful or can never be made. With some groups of drugs (e.g., analgesics), extensive study and precise methodology have yielded useful information on relative efficacy. But in most situations, such information can be acquired only through studies encompassing three to five years of use in many more patients than are used to compare drugs with a placebo for the introduction of a drug into commerce. It is really only after practitioners use a drug extensively that relative safety and efficacy in practice can rea determined.

The Bureau of Dr suggested the packa sert as a possible m communicating infor on relative efficacy o to the physician. I fi objectionable, since not believe the ph should have to rely source for final sc truth. There is also tical objection: Sin physicians actuall pense drugs, they see the package ins any event, I would tain that the phy should know what d wants and why witho pending on the gover or the manufacturer him.

Undoubtedly, phys are swamped by exc numbers of drugs in therapeutic categorie I am well aware that drugs within such at gories could be elim without any loss, o haps even some pr the practice of me But, in my opinion, n the FDA nor any th single group has the tise and the wisdom sary to determine th "drug of choice" i areas of medical prac

Maker of Medicine

n th G. Kohlstaedt, M.D.,
Vice President,
edical Research,
E Lilly and Company

I my opinion, it is not e nction of any governor private regulatory e y to designate a "drug c ice." This determinaon hould be made by the ysician after he has re- l full information on e roperties of a drug, n hen it will be based on s xperience with this r and his knowledge of e ndividual patient who s king treatment.

I n evaluation of com- a ive efficacy were to be a , particularly by gov- n ent, at the time a new r is being approved for a eting, it would be a r disservice to medi- n nd thus to the patient t consumer. For exam- e when a new therapeu- c ent is introduced, on e asis of limited knowl- g it may be considered e more potent, more f tive, or safer than r ucts already on the a et. Conceivably, at i time the new drug u l be labeled "the drug f oice." But as addi- o l clinical experience is c nulated, new evidence a become available. a r, it may be apparent that the established products should not be so easily dismissed.

Variation in patient response to drugs constitutes one of the major obstacles to the determination of "drugs of choice." We are just beginning to open the door on pharmacogenetics, but it is evident that genetic differences cause wide variations in the way drugs are absorbed, metabolized, etc. This fact alone is sufficient to make unrealistic the idea that there is one drug in each class to be used for every human being.

The problem of determining relative drug efficacy is an extremely complicated one. Comparison with other drugs of the same class should not be a prerequisite for marketing a new substance. In some therapeutic areas, it may be difficult to make accurate comparisons. For example, in the treatment of infections it is not possible to conduct crossover studies. Recovery may be influenced by factors which cannot be controlled or measured, i.e., natural host resistance and virulence of infective agents. A drug's acceptability must often be judged on the basis of its own performance, and this may be limited to experience in a relatively small patient population. If the introduction of a new drug must await the adequate establishment of relative efficacy, the duration of clinical trial and extent of studies would be greatly prolonged, particularly for rare or unusual conditions. The availability of a new drug would be delayed. Many patients might suffer needlessly and lives might be lost.

Relative efficacy can best be established by experience in a general patient population through regular channels of clinical practice. The physician considers the patient as a whole, which means the patient often has multiple problems and drugs must be selected with this in mind. Hence, a "drug of choice" in an uncomplicated case may not be the best drug for a patient with associated problems. Publication of well-controlled studies in medical journals may provide comparative evidence; discussions at medical meetings, presentations at postgraduate courses, and the new audiovisual technology may bring evidence to physicians on comparative therapy. In a free medical marketplace, a drug that does not measure up will fall into disuse. For example, broad clinical experience has established vitamin B_{12} as the "drug of choice" for the treatment of primary pernicious anemia. No amount of advertising or promotional effort by the manufacturer could increase the use of liver extract for this anemia. However, a physician may wish to employ parenteral liver preparations for a special purpose.

In the field of surgery, peer review in the hospital has brought significant improvement in the use of new techniques and procedures. Something of this nature would be useful in the area of drug therapy. However, it should be developed by the medical profession itself and would necessitate, for its proper function, an improvement in the dissemination of reliable data on clinical pharmacology of drugs under consideration.

Ideally, information on the relative efficacy of drugs should be gathered and assessed by the physicians who actually administer the specific agents to a specific patient population. To do this, they will need even more information on the drugs they use – information that the pharmaceutical manufacturers must begin to provide if government regulation of *"drugs of choice"* is to be avoided.

Cancer of the Colon and Rectum

Epidemiology and Possible Causative Factors

DENIS P. BURKITT

IN THE WESTERN WORLD CANCER is the second most common cause of death after cardiovascular disease.

With the exception of bronchial carcinoma, tumours of the large bowel are responsible for more deaths from cancer than any other form of neoplasm.

In the U.S.A. alone over 75,000 new cases of cancer of the colon and rectum are diagnosed every year.

A New Approach

In an effort to understand the mechanisms involved in malignant transformation of tissue cells, the emphasis in cancer research has tended to be at subcellular level. Admittedly, epidemiological studies have been attracting increasing interest, but those on men still receive less attention than those on mice. Even when epidemiological studies are given due prominence, specialization tends to blinker the cancer research worker that non-malignant disease is well outside his sphere of interest.[1]

Those responsible for cancer registries pay little attention to benign tumours and even less to other non-neoplastic disease. The electron microscope and other modern and sophisticated techniques enable the visualization of the minute and this approach has not been matched by an overall view of the problems confronting us. Our knowledge of twigs and leaves increases at the expense of understanding trees, let alone woods, or forests.

A malignant tumour, be it in breast, bladder or bowel, must be viewed in its relationship not only to benign companions but also to other diseases of the organ concerned and event to associated diseases affecting other parts of the body.

The Relevance of Relationships

Clues to the causation of a disease may be found by comparing its geographical distribution with that of a disease whose cause is already understood. This approach has tended to be overlooked, particularly in the field of cancer.

If two or more effects are produced by a common cause they will both or all be found to be associated with one another, where the common cause operates, but will be rare or absent where the cause is missing.

If two causes tend to be associated with one another all the effects of each will also tend to be associated.

Conversely, an observed tendency for certain diseases to be associated with one another epidemiologically suggests the possibility that they may be at least in part the result of common or related factors.

Moreover, if two or more diseases are the result of common or related factors they will both or all be found most frequently in the geographical regions or the sections of communities most exposed to the causative factors and will consequently be found together in individual patients more often than would otherwise be expected.

Conversely again, an observed association between certain diseases in individual patients suggests the possibility of a common or related causative factor.

Such observations can provide the foundations on which hypotheses of possible aetiology can be built.[2,3]

An attempt will be made to construct a hypothesis for the cause of large bowel cancer based on its relationship with some other diseases characteristic of modern western civilization. These include not only other non-infective disease of the colon and rectum such as benign tumours, diverticular disease, appendicitis and ulcerative colitis, but also such apparently diverse conditions as varicose veins, deep vein thrombosis, coronary heart disease, gallstones and obesity.

Presented at the United Hospitals and American Cancer Society, Ramsey County Unit, Cancer Symposium, St. Paul, March 28, 1972.

Dr. Burkitt is a member of the External Staff of the Medical Research Council of Great Britain, and is a Fellow of the Royal College of Surgeons of England.

See editorial, page 815.

Vultures and Carcasses

The simplest way to locate a dead animal in the African bush is to look for tell-tale vultures flying overhead. The known association between them enables the more easily found birds to be used as a guide to the more concealed carcass.

This same approach could be used epidemiologically if those investigating different diseases (corresponding to carcasses and vultures) were less exclusively specialized.

Let us consider some diseases associated with bowel cancer, which may play the part of the vultures around the carcass we wish to investigate.

Non-infective Diseases of the Bowel

Cancer and Polyps

Benign and malignant tumours of the colon and rectum are closely associated in so many ways that Morson and Bussey[4] consider them merely different manifestations of the same cause. They are closely associated:

In Anatomical Distribution—The distribution of both benign and malignant tumours of the colon and rectum are closely similar.[5]

In Individual Patients—There is a close association between benign and malignant tumours in individual patients.

Bockus et al.[5] found that whereas polyps were found in only 12% of cancer free colons in patients over the age of 45 years, they were found in 21-25% of colons with cancer in the same age group.

Similarly, Rider et al.[6] showed that cancer of the colon and rectum was 16 times as common in patients with polyps than in patients without polyps.

In Age Distribution—The age distributions of both benign and malignant tumours are very similar.[5]

Experimentally—Both benign and malignant tumours can be induced by the same substances in experimental animals.[7,8]

In Geographical Distribution—No form of cancer is so closely associated with modern economic development as cancer of the colon and rectum. The variations in ratio of colon and rectal involvement are small compared with the varying in incidence of large bowel cancer as a whole.

Throughout sub-Saharal Africa cancer of the colon and rectum accounts for about 2% of all malignant tumours[9] and this figure is not greatly influenced by age since most forms of cancers a more prevalent in later life.

Where bowel cancer is rare simple tumours a almost unknown.[10,11] Where the incidence of m lignant tumours increases that of benign tumou increases at a much greater rate, and consequent are present in over 10% of the adult population i countries with the highest rates of bowel cancer.

Cancer and Diverticular Disease

Cancer and diverticular diseases of the colo are closely associated:

In Anatomical Distribution—In regions whe they are both common their maximum frequenc is in the distal colon with diminishing frequenc towards the proximal colon.

In Sex Distribution—Both conditions are con moner in women.

In Individual Patients—Little has been done t relate cancer and diverticular diseases in individu patients. Parks and Connell[12] found 11 cases c cancer of the colon in 445 patients with advance diverticular disease, which is many more tha would be expected even in patients over the ag of 60.

Chronological Emergence—Diverticular diseas was rare in Britain and the U.S.A. until after th first world war. Since that time the frequency ha increased enormously.[13] It is not known whe bowel cancer first emerged as an important clinica entity in the western world. We do know how ever that some 30 years ago the frequency of bot cancer[14,15] and diverticular disease[16] in Americar negroes was only about half of that in the whit population, whereas today their incidence is com parable in the two races. This suggests that bot diseases may have increased during approximately the same period. Experience in developing coun tries suggests that cancer frequency rises a littl before that of diverticular disease.

Geographical Distribution—There is a very close association between the geographical distri bution of bowel cancer and diverticular disease Both have their maximum and minimum fre quency in the same communities and availabl information suggests that the same applies in area of intermediate frequency.

Appendicitis

Cancer of the colon and rectum and appendici tis are associated.

In Geographical Distribution—Both cancer o the large bowel and appendicitis have their maxi mum and minimum incidence in the same com-

unities.[9,17]

In Chronological Emergence—The frequency of appendicitis always rises many years before that of bowel cancer—never the reverse.

Even if both diseases were, as I believe, related to a common cause, this relationship in individuals would not be expected since they affect people at entirely different periods of life. Responsible environmental factors may be present in youth, but not persist.

McVay[18] (1970) did in fact detect an association between cancer of the bowel and previous appendicectomy. Those who suspect the diagnosis of chronic appendicitis would consider any such association of doubtful validity.

Ulcerative Colitis

This disease is very closely associated with cancer of the large bowel:

In Individuals—Over 40% of patients with extensive ulcerative colitis for over 25 years are said to develop cancer of the colon or rectum.[19]

In Geographical Distribution—Ulcerative colitis is almost unknown in areas where bowel cancer is rare.[20,21,22]

Possible Guides

Applying the principle of the vultures and carcasses referred to above, a search for the causes of diverticular disease and appendicitis may throw light on causes of tumours and ulcerative colitis.

In a search for the cause of bowel disease food is the first environmental factor to be considered, since this determines the nature of the faeces which contribute most to the environment of bowel mucosa.

Diverticular disease and appendicitis are rare or unknown in communities consuming high residue diets and have their highest frequency among those who have relatively recently changed from a high to a low residue diet.

Appendicitis rose in frequency in the western world shortly after the introduction of roller mills in the 1880s. This higher extraction process in making white flour removed nearly all the cereal fibre and in subsequent years the amount of bread consumed fell by about half. The frequency of appendicitis does not appear to rise in developing countries until white flour partially replaces traditional unprocessed carbohydrate foods.

Diverticular disease, in contrast to appendicitis, is a complaint of later life, and so presumably requires much longer exposure to the causative environment. In the U.S.A. it was little more than a surgical curiosity before the first world war and only became a well recognized clinical entity in the 1920s.[13] In developing countries it is almost confined to the top socio-economic groups who have to a large extent adopted western type food.

Since unabsorbable fibre is the fraction of food that reaches the colon with least change it is more likely to affect that part of the intestine than digestible components of food, little of which reach the large bowel. This fact, together with the observed relationship between removal of dietary fibre and a subsequent rise in frequency of diverticular disease and appendicitis, suggests that a fibre-depleted diet may be causally related to these diseases.

Food Fibre and Bowel Behaviour

Extensive studies in many countries in Africa and India and in different communities in England have demonstrated a direct relationship between dietary fibre and both intestinal transit time and stool weight and consistency.[9,23,24,25,26] African villagers on a high-residue, little-processed diet have been shown to pass 80% of swallowed radio opaque markers within about 30-40 hours and to evacuate on average 300-400 gms of unformed stool daily.

Volunteers on standard English diet had intestinal transit times averaging over 70 hours and evacuated less than 150 gms of formed stool daily.

White students in South Africa, Indian nurses in India, vegetarians in England and more educated Africans on a mixed diet, showed intermediate figures in both intestinal transit times and stool weights.[26]

Postulated Mechanisms Relating Non-infectious Diseases of the Bowel with Dietary Fibre

Diverticular Disease

Painter[27,28,29] has shown the manner in which the colon contracts in response to small firm faeces. These contractions form closed segments in which high pressures are built up and it is these that are believed to cause protrusions of mucosa through the muscular wall.

Appendicitis

A similar mechanism is believed to be responsible for appendicitis.[17,30] Intraluminal pressures can build up behind an impacted faecalith (a product of low residue diet), a stricture or pre-

sumably muscular contraction similar to that demonstrated in the colon. Mucosa devitalised by these pressures would be vulnerable to bacterial invasion. It has been postulated that alterations in bacterial flora of the faeces due to dietary changes may be a contributory factor.[31]

Benign and Malignant Tumours

As pointed out above there are strong grounds for suspecting common aetiological factors for benign and malignant tumours.

Any acceptable hypothesis must take into consideration the following facts:

(a) the rarity of these tumours in developing countries and in animals;

(b) the relationships between tumours and other non-infective diseases of the large bowel;

(c) the relationship between the incidence of intestinal cancer and the fibre content of diet;

(d) the rarity of cancer in the small intestine;

(e) the much greater differences between increase in frequency of tumours in the distal colon relative to the proximal colon when comparing areas of high and low overall incidence;

(f) the much smaller difference in colon/rectum ratios in different communities than in overall incidence of large bowel tumours;

(g) the observation that in rats maintained in a sterile environment no tumours develop, following administration of substances that produce tumours in the colon and rectum of normal animals.[32,33] This suggests that bacteria play an important role:

(h) the differences between the bacterial flora in stools from communities with high and low risks of developing bowel cancer;[34,35,36]

(i) the fact that some 30 years ago negroes in North America had a much lower frequency of large bowel cancer than the white population.[14,15]

The following suggested mechanism would be consistent with these observations:

The rarity of tumours in the small bowel and the almost total absence of epithelial tumours suggests that the factor responsible for inducing tumours is not ingested, since its action only becomes apparent in the colon and increases towards the distal colon.

A carcinogen dependent on bacterial activity would be largely limited to the colon and rectum, whereas ingested carcinogens would be expected to act on the small intestine.

A carcinogen formed in the large bowel would increase in intensity from the proximal to the distal portions, and might be expected to have its maximum effect in the sigmoid colon and rectum. When faecal arrest results from a low residue diet, any carcinogens in the faeces would be held in particularly prolonged contact with the mucosa of the sigmoid colon in a concentrated form in a small faecal mass. It is here that maximum tumour incidence is found.

It has been shown that the bacteria which are more numerous in the stools from areas with a high frequency of bowel cancer can degrade bile salts to substances known to be carcinogenic. Any faecal arrest would not only provide more time for proliferation of bacteria, but also for their action on bile salts. The bacterial changes may also reflect alterations in the nature of the bowel content due to the quality of food eaten.

Additional Incrimination of a Fibre-depleted Diet

Cancer and other non-infective diseases of the large bowel are epidemiologically associated with varicose veins, deep vein thrombosis, coronary heart disease, gallstones and obesity. Can fibre be considered as a causative factor in any of these diseases associated with bowel cancer but not involving the gastrointestinal tract?

As shown above, faecal arrest results in increased pressures within the bowel lumen, and also causes raised intra-abdominal pressures during straining at stool. Since raised intra-abdominal pressures are readily transmitted down the leg veins after the valves have become incompetent they must be taken by the valves when still competent. Such pressures could lead to valvular incompetence with resultant changes in the superficial veins recognized as varicosities and in the changes in the deep venous plexuses which in the presence of venous stagnation may predispose to thrombosis.[37] Here again, fibre deficiency could be an important causative factor.

High levels of serum cholesterol are also associated with low residue diets and vice versa. A relationship between cholesterol metabolism and dietary fibre[38] could explain the association between bowel cancer and both coronary heart disease and cholesterol gallstones.

Removal of fibre from carbohydrate foods almost inevitably results in overconsumption of the refined product. This may explain the association of diseases presumably caused by overconsumption of starch and sugar with those caused by a fibre-deficient diet.[31] Obesity diabetes and dental

aries are closely related to overconsumption of efined carbohydrate.

Conclusion

The argument outlined above, incriminating a ibre-deficient diet in the cause of bowel cancer, consistent with epidemiological and other evience.

This suggests that a return to a high residue diet nd particularly to wholemeal flour might not only ignificantly reduce the frequency of America's second commonest cause of death from cancer but also that of many other major health problems of this country. Moreover, if communities in developing countries could be persuaded not to copy indiscriminately the food habits of the more economically developed countries, in particular the consumption of refined carbohydrates, future generations might be saved from suffering in endemic proportions some diseases characteristic of modern western civilization.

"You are old, Father William," the young man said,
"And your hair has become very white;
And yet you incessantly stand on your head—
Do you think, at your age, it is right?"
"In my youth," Father William replied to his son,
"I feared it might injure the brain;
But now that I'm perfectly sure I have none,
Why, I do it again and again."*

*From Lewis Carroll's: Your are old, Father William.

Left Ureteral Obstruction

Following Ileac Diversion

LLOYD C. GILMAN, M.D., GERALD W. IRELAND, M.D. AND
ALEXANDER S. CASS, M.D.

THE GREATER INCIDENCE of obstruction of the left ureter following ileac diversion has been documented[1] and attributed to angulation of the left ureter as it coursed through the sigmoid mesentery.

Five cases of left ureteral obstruction with secondary pyelonephritis or stone formation have occurred in 87 ileac diversions performed during the last five years at St. Paul Ramsey Hospital and Gillette State Hospital for Crippled Children. Exploration in three of these cases has revealed an obstruction of the left ureter as it passed under the inferior mesenteric artery.

Department of Urology, St. Paul Ramsey Hospital; and Urology Service Gillette State Hospital for Crippled Children, St. Paul and University of Minnesota Medical School, Minneapolis.

Fig. 1 (Case 1)—Excretory urogram showing delayed function in the left kidney and a possible left ureteral stone.

Case Reports

Case 1

A 35-year-old male with traumatic paraplegia and a neurogenic bladder of 16 years' duration had an ileac diversion performed in October 1967. In May 1969 radiological evaluation revealed a stone in the left renal pelvis and the patient refused surgery. In November 1969 he was admitted with left pyelonephritis and further radiological evaluation revealed an obstruction of the middle one-third of the left ureter with the stone immediately above this area (Figures 1 & 2). The stone was removed at surgical exploration through a ureterotomy in the upper ureter and an obstruction to the ureter was found where it passed under the inferior mesenteric artery. Division of the inferior mesenteric artery relieved the obstruction and postoperative excretory urograms showed no obstruction of the ureter.

Fig. 2 (Case 1)—Retrograde ileostogram demonstrating an obstruction in left ureter.

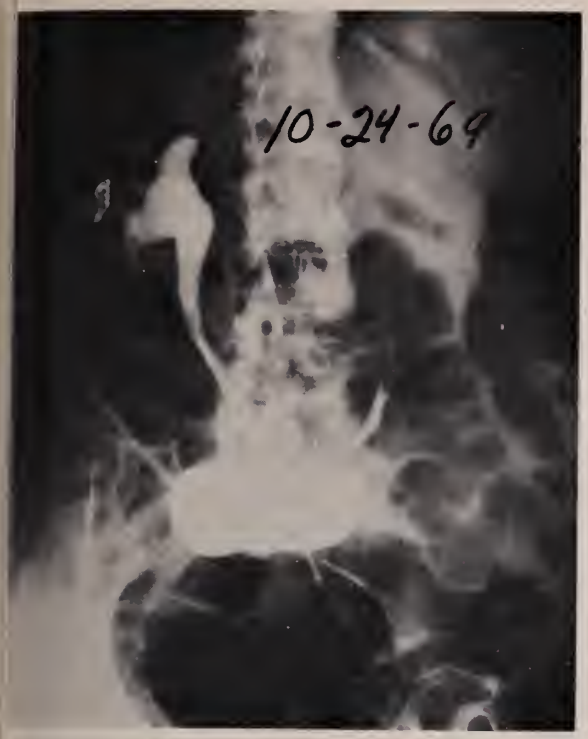

Fig. 3 (Case 2)—Retrograde ileostogram showing an obstruction in the left ureter.

Fig. 4 (Case 3)—Excretory urogram revealing dilated upper left ureter and calyces with a stone present in the ureter.

Case 2

A 45-year-old female with a neurogenic bladder due to multiple sclerosis had an ileac diversion on May 11, 1967. She was admitted with left pyelonephritis on October 1969. Excretory urogram and retrograde ileostogram (Figure 3) demonstrated an obstruction of the middle one-third of the left ureter with a stone in the proximal ureter. At exploration the stone was removed from the renal pelvis and an inflammatory stricture was found in the ureter where it passed under the inferior mesentric artery. The stricture was treated by a Davis intubated ureterostomy. Postoperative excretory urograms showed no dilatation of the left ureter.

Case 3

A 47-year-old female with multiple sclerosis and a secondary neurogenic bladder had an ileac diversion performed on January 16, 1969. She was admitted with left pyelonephritis on October 26, 1969 and radiological evaluation demonstrated a stone and left hydronephrosis above the obstruction of the middle one-third of the ureter (Figure 4). At exploration the stone was removed through a ureterotomy in the upper ureter and an obstructing inferior mesenteric artery was divided. No dilatation of the ureter was present on subsequent radiological examination.

The two remaining cases have each had one attack of pyelonephritis and radiological evaluation has revealed a relative obstruction in the mid third of the left ureter with only slight dilatation of the left ureter above this point. These findings are regarded as presumptive evidence of inferior mesenteric artery obstruction at the mid third of the left ureter and exploration will be carried out if there is stone formation, further pyelonephritis or increasing obstruction.

Discussion

The operative technique for bringing the left ureter to the right iliac fossa during these ileac diversions consisted of blunt dissection in the root of the mesocolon dorsal to the inferior mesenteric artery and ventral to the great vessels. The left ureter was then pulled through this opening which was large enough to allow the ureter to lie in a gentle curve from the left renal pelvis to the right iliac fossa.

The left ureter also follows an anterior course as it passes from the retroperitoneum of the left side forwards to its anastomosis with the proximal end of a short ileac loop in the lower right abdomen. Along this course the left ureter hooks under the inferior mesenteric artery. The treatment in our cases with obstruction by the inferior mesenteric artrey was to ligate and divide the artery after occlusion by a bulldog clamp for 10 minutes to insure adequate anastomatic blood supply to

the descending and sigmoid colon.

In bedridden paraplegics and multiple sclerosis patients the inferior mesenteric artery follows a posterior course to the sigmoid colon which lies dependently against the postabdominal wall. This posterior course of the inferior mesenteric artery and the anterior course of the left ureter could accentuate the hooking of the ureter under th artery which would be avoided if the left uret was brought through the mesocolon ventral to th inferior mesenteric artery. One cause for ureter obstruction following ileac diversion would b eliminated.

It's the Law

General Practitioner's Duty To Seek Con ultation

A man was taken to a hospital emergency room because he was nervous and shaky. His wife stated he had been drinking and had been having hallucinations.

The patient was examined by a general practitioner who was not his regular family physician. This physician made a diagnosis of "alcoholism DT's." He was hospitalized.

By the next day, the patient was restless and still having hallucinations. When the physician saw him at 8:30 A.M., the man was in a comatose condition, and by 3:00 P.M., he had not eaten. The physician ordered an intravenous feeding and called for neurosurgical consultation. The patient died at midnight.

The autopsy revealed that the patient had had a subdural hematoma for approximately 48 hours.

The patient's widow and children sued the general practitioner and the hospital claiming that the physician negligently failed to obtain appropriate consultation.

The jury found that the physician was not negligent in failing to call a specialist on initial examination. The appeal court noted that there was no evidence that the physician had violated any standard of care. They further noted that a general practitioner is not required to consult a specialist on every conceivable complication that might arise.

Tetanus in Minnesota

MARK V. DAHL, M.D.

TETANUS IS A rare, often fatal disease resulting from infection with *Clostridium tetani*. This bacterium is present in the soil,[1,2] and is occasionally cultured from the gastrointestinal tracts of healthy people.[3] When present in a suitable anaerobic environment such as necrotic tissue, the organism produces an exotoxin which binds to neural tissue and causes a progressive disinhibition of nerve impulses resulting in the clinical disease tetanus.[4]

The purpose of this retrospective study is to review the experience with tetanus at the University of Minnesota Hospital from 1955 to 1971. Particular attention is given to events leading to death and influencing mortality in these patients.

Methods

Fifty-six patients with tetanus were admitted to the University of Minnesota Hospital between January 1, 1955 and June 30, 1971. The diagnosis of tetanus was questionable in three patients (all non-fatal), and these patients were excluded from the study. The clinical diagnosis of tetanus was well-established in the remaining 53 patients. Medical records were reviewed and clinical data tabulated. Autopsy reports of 17 patients who died were also reviewed.

Results

Thirty-eight patients (72%) lived outside a 50-mile radius of Minneapolis-St. Paul. Only four patients (8%) were residents of these cities proper. All patients were white and the males outnumbered females 37 to 16 (2.3:1). The patients ranged in age from one week to 82 years with a mean age of 43. Two patients were less than one month old. The distribution of age groups is depicted in Figure 1. Thirty-six patients (68%) developed tetanus during the six summer months from April through September (Figure 2).

Thirty-two patients (60%) reported no previous immunization against tetanus. Of these, six had received an initial tetanus toxoid immunization after the injury which preceded development of tetanus. Ten patients (19%) reported immuniza-

tions against tetanus prior to injury. The immunization status was unknown in 11 patients (21%).

A site of infection was noted or reported by all but three patients (94%). Farm machinery produced 12 of the precipitating injuries (24%), and puncture wounds accounted for 12 others (24%). Five puncture wounds resulted from rusty nails. Infection with *C. tetani* also resulted from crush injuries, gunshot wounds, incomplete abortions, burns, and chronic leg ulcers. Operations apparently introduced infection in two patients. No patients were known narcotic addicts.

In 26 patients (50%), the site of injury was the upper extremity. Four of eight patients (50%) died with infection sites on the head or trunk, whereas 12 of 32 patients (38%) died from initial infection on an extremity.

The incubation period between inciting event and onset of symptoms was three to 35 days with a mean of 10 days and a median of seven days. It was not possible to determine the incubation period in eight patients. One of 13 patients (8%) with an incubation period longer than 10 days eventually died during hospitalization. In contrast, 10 of 25 patients (40%) with incubation periods less than seven days died during the course of the disease.

The mean onset time between first symptom and first convulsion was 48 hours among 39 patients who developed convulsions. Most of these had been treated with various tranquilizing drugs prior to the first convulsion. Five of nine patients (56%) with onset times of 36 hours or less eventually died. Two of 12 patients (17%) with onset periods longer than 60 hours died.

Inability to open mouth was the most frequently chief complaint (20 patients). Difficulty swallowing (8), stiff neck (8), and painful neck (7) were other common chief complaints. Other patients reported stiff legs, back pain or stiffness, jaw pain, jerking of an arm, gagging, abdominal cramping, and various sensations in the throat as the initial symptom. There was no relationship between chief complaint and mortality.

Clostridium tetani was grown from culture of infected wounds of seven patients (13%). Three of these (43%) eventually died during hospitalization. An extremity or digit was amputated from 16 patients of whom five eventually died during the course of their disease (31%). Tracheotomy was performed on 40 patients. All 17 patients who died had previously undergone tracheotomy.

All 53 patients received tetanus antitoxin prior to or during hospitalization. There were three deaths among seven patients who received human tetanus antitoxin, and 14 deaths among 46 patients who received horse antitoxin. There was no relation of mortality to either initial dose or total dose of tetanus antitoxin. The mortality rate of patients who first received tetanus antitoxin prior to the onset of convulsions (five of 12) did not differ significantly from the mortality rate of patients who first received tetanus antitoxin at or after onset of convulsions (12 of 41). Gavage or gastrostomy feedings were given to 32 patients of whom 11 died, (34%).

Body temperatures above 100°F were recorded during hospitalization in all 53 patients. The degree of elevation or pattern of body temperature over time reflected convulsive activity or complicating infection but did not appear to have prognostic significance. Characteristically, the blood pressure fluctuated widely, but its degree or pattern did not indicate impending death except to the extent a low blood pressure indicated shock. Various laboratory tests including analysis of the cerebrospinal fluid also had no prognostic significance.

Numerous drugs were administered. Antibiotics were given to all 53 patients. Major muscle relaxants such as curare, gallamine, and succinyl choline were given to 24 patients with 12 subsequent deaths (50%). Minor muscle relaxants such as methocarbamol were used in four patients. Forty patients received barbiturates, 39 patients received phenothiazine tranquilizers, and 17 patients received minor tranquilizers such as meprobamate, diazepam, and chlordiazepoxide. Six patients were treated with diazepam and two of these died (33%). Non-barbiturate sedatives such as paraldehyde and chloralhydrate were administered to 12 patients, and magnesium sulphate was administered to five patients.

Autopsies were performed on all 17 patients who died. Seven patients (41%) died within five days and 12 patients (71%) died within 10 days after admission to the hospital. One patient died as late as 28 days after admission. Bronchopneumonia was noted at autopsy in eight patients, and atelectasis in seven. Pulmonary embolism was present in six patients (35%). Other findings at

autopsy included septicemia (5), gastrointestinal ulceration (4), myocardial hemorrhage, necrosis, or infarction (3), peritonitis (1), pyelonephritis (1), and acute supperative cholecystitis (1).

Comments

The 17 deaths in this series of 53 patients with tetanus represents a mortality rate of 32%. This approximates the death rate currently being reported by other institutions.[5-10] The mortality of tetanus has decreased since World War II.[11-13] This is attributable primarily to the role of antibiotics in both chemical elimination of the *Clostridium tetani* organism from the infected wound, and control of superinfections especially pneumonia. New anesthetic and sedating techniques and medications probably also contribute to this world-wide reduction of mortality from tetanus.

Most patients were males from rural areas. Farmers are particularly likely to sustain injuries with soil-contaminated objects. Contact of a wound with soil increases the likelihood of infection with *C. tetani*.[1,3] More than one-fourth of infecting wounds were from farm equipment. Differences of immunization practices may also account for the apparent predisposition of rural populations to tetanus. The extent to which the University of Minnesota's role as a referral center acts on selection of patients is not known. Tetanus was treated between 1955 and 1971 in at least four other Minnesota hospitals.

Most tetanus occurred in the summer (Figure 2). The paucity of cases during the winter months probably reflects both the agricultural habits of the state, and the severity of Minnesota winters. Wounds by soil-contaminated objects would be less common in winter.

The age of patients ranged from one week to 82 years (Figure 1). Immunization status is most likely to be deficient in the pediatric and over-fifty age groups, and most patients were included in one of these two groups. Two patients had neonatal tetanus. The umbilical stump was grossly infected in one of these infants. The mortality rate was approximately equal in all age groups. Others have noted higher mortality rates in small children and persons over age 60 years.[9,13]

The frequency of tetanus treated at the University of Minnesota decreased during the 16 years included in the study. Only four patients were treated for tetanus from 1967 to 1971. The number of admissions to the University of Minnesota Hospital during the 16 years remained relatively constant at about 15,000 patients each year.

A majority of patients reported they had never received even a single immunization against tetanus. Documented cases of tetanus in patients previously immunized are rare.[14] Ten of 43 patients in this study reported prior immunization. In many patients, the last immunization had been given many years previously. Protection by immunization requires periodic booster injections. History may not always be reliable in accessing immunization status.

The well-known relationship between the mortality rate and the incubation period is demonstrated in this study. The shorter the period between injury and development of symptoms, the higher the mortality rate.[1,5,7-9,13,15] This may be the best indicator of prognosis in any given patient.

There is another well-known relationship between the onset period and the mortality rate. The onset period is the interval of time between appearance of the first symptom and the initial convulsion. A prolonged onset period indicates a more favorable prognosis.[1,5,7-9,13,15] This relationship is sometimes masked by difficulty defining a convulsion in some patients, the incideous onset of the initial symptom, and the use of numerous drugs which delay or prevent onset of convulsions. However, the relationship is valid, and is demonstrated in this series.

Cultures from most patients were negative for *C. tetani*. Perlstein similarly reported only four positive cultures in his series of 59 patients.[15] The diagnosis of tetanus is a clinical diagnosis, and is not dependent on finding the etiologic organism in culture.

Forty patients had undergone tracheostomy. Elective tracheostomy is performed on all patients with pharyngeal or laryngeal involvement. A major cause of death in untreated tetanus is asphyxia from spasm of the glottis, diaphragm, or intercostal muscles.[16,17] Spasm of the glottis was not a factor in death of any patient in this series, since all patients who died had undergone tracheostomy.

Treatment

Treatment must be tailored to each individual patient. Probably no single therapeutic regime is suitable in all respects in any given patient.

At the University of Minnesota, the anesthesiology department has prime responsibility for management of the total paralysis regime and overall supervision of treatment. The departments of

medicine and pediatrics function to maintain nutrition and electrolyte balance, and prevent and treat complications. Surgeons perform debridement, tracheostomy, gastrostomy and follow-up care of the infected wound. Neurology follows the patient in a consultative role. Specially trained nurses are assigned to deliver continuous care on a 24-hour-a-day basis. Nurses who previously had cared for patients with tetanus are assigned when possible.

Treatment is initially directed at removing the source of toxin, controlling spasms, and preventing respiratory arrest.[16] Initially 1000-2000 units of human tetanus immune globulin are administered intramuscularly to neutralize unbound toxin. Christensen has advocated injection of small amounts into multiple sites to speed absorption since once toxin is fixed to nervous tissue it can not be neutralized.[18]

Tracheostomy is performed early in the course of hospitalization on any patient where pharyngeal or laryngeal involvement is present or anticipated. A double-cuffed tracheostomy tube allows optimum care. The wound is amputated or debrided widely. When debridement is performed, the wound is totally excised if possible. The deep fascia, any involved muscle, and at least a two centimeter margin of skin around the wound is also excised. The wound is allowed to heal initially by secondary intention although it may be closed at a later date if indicated.[18] Dressings are applied lightly and initially kept wet with 3% aqueous hydrogen peroxide or a 1:4000 aqueous solution of potassium permanganate.

Penicillin is the drug of choice to eliminate the clostridium organism chemically. Ten million units of aqueous penicillin G are administered by continuous intravenous drip during the first 24 hours.[18] Thereafter, one million units of procaine penicillin are administered daily intramuscularly for six to 10 days.[14] Kanamycin streptomycin, or tetracycline may be administered to aid elimination of synergistic gram-negative bacteria.

Recently intravenous and oral diazepam has been used both as a sedative and muscle relaxant.[19] An initial intravenous injection of five mgm is administered, and increased five mgm every two hours until convulsions are controlled or limits of toxicity are reached. Up to three mgm/kilogram/day is occasionally used. Femi-Pearse has treated one patient with 40 mgm/kilogram/day.[19] The dose of diazepam is titered by clinical parameters. Proper control is obtained when the temperature remains stable and convulsions occur only with stimulation. At this dose range, the cough reflex is still active and assists in clearing pulmonary secretions. If additional medication is needed, gallamine 20-60 mgm every twenty minutes may be given intravenously. In these patients, intermittent positive pressure ventilation is necessary. Oversedation is a definite hazard.

Convulsions are occasionally stimulated by rectal or bladder fullness although viscerally stimulated convulsions are less common when diazepam is used. An indwelling bladder catheter may itself precipitate convulsions. In these cases, intermittent catheterization or cystotomy may be performed. If an indwelling catheter is used, it is cleansed daily with alcohol or disinfectants, and changed at least every two weeks. An antibiotic ointment is applied to the urethral meatus, and the urine acidified if feasible to minimize infection. Tap water enemas reduce visceral stimulation from the rectum.

One thousand units of human tetanus immune globulin are administered daily for four or five days by intramuscular injection. Equine tetanus antitoxin is no longer used.

The central venous pressure and urine output and specific gravity aid management of fluids and electrolytes, and allow early diagnosis of shock should it occur. The patient may require large amounts of fluids to replace excessive loss from perspiration during convulsions. A cooling blanket may be necessary to reduce fever from convulsions or medullary intoxication. Gavage or gastrostomy feedings do not appear to increase mortality in our experience, and may be used after the acute phase. Care must be taken to avoid vomiting and aspiration from overfilling the stomach. The gastrostomy catheter may be used to decompress the stomach if distension is noted. Because stress ulcers are common, frequent administration of antacids is recommended. The legs are wrapped to the upper thighs with six-inch-wide elastic bandages. Each day the legs are unwrapped and examined for erythema and edema indicating thrombophlebitis.

Vigorous tracheal aspiration under sterile conditions and proper tracheostomy care are essential if a complete paralysis regimen is used. Serial daily cultures of tracheal aspirate and urine are helpful as guides to proper selection of antibiotics when lung or urinary tract infection occurs. In-

ceting organisms are usually klebsiella, aero-bacter, pseudomonas, and staphlococci.[18] Arterial blood gas determinations are usually necessary for proper regulation of positive pressure ventilation when used.

Hematocrit and examination of stool for occult blood are performed frequently. Anemia develops in nearly every patient with severe tetanus and may require transfusion. The anemia may develop from peptic ulceration, but more often is probably the result of toxic depression of the bone marrow. During recovery, active hematopoiesis is usually resumed.

If a total paralysis regimen with gallamine is used, the eyelids are kept closed. Methylcellulose eyedrops are instilled three times daily in each eye. If conjuctivitis develops, neosporin ophthalmic ointment is usually preferred pending results of culture.[14]

Prophylactic measures are taken to prevent contractures and decubitus ulcers. Bedboards and footboards are helpful. The extremities are passively brought through full range of motion at least once daily. Decubitus ulcers may be prevented by changing position of the patient each hour. Sheepskins or alternating pressure mattresses relieve ischemia of the skin and reduce shearing forces of bedsheets on pressure areas. The skin is kept dry as well as clean. Frequent inspection of skin especially over sacrum, trochanters, ischial tuberosities, and calcanea is important.

Clinical tetanus does not confer immunity. Active immunization with tetanus toxoid is begun during the recovery phase.

No patient received hyperbaric oxygen therapy. Laboratory and clinical studies indicate that treatment with hyperbaric oxygen is not warranted.[20,21]

Recently Saunders advocated intravenous administration of betamethasone. Three hundred sixty-two infants with neonatal tetanus received 24 to 32 mgm daily with a reduction of mortality from 61% to 37%.[22] Betamethasone has not been used to treat tetanus at the University of Minnesota Hospital.

Kerr used anticoagulants to minimize the possibility of pulmonary embolism.[23] Pulmonary embolism was present at autopsy in six patients in this series.

Regardless of therapy, tetanus will appear to progress for four to seven days. Because the half-life of tetanus toxin bound to neural tissues is long, the patient will usually remain stable for two or three weeks before improvement is noted.

It is apparent from autopsy data reviewed in this study that serious complications are present in most of the patients with tetanus who die. Prevention of complications and therapeutic advances may allow further reductions of the mortality rate. The major complications are infections such as: pneumonia, septicemia, peritonitis, cholycystitis, and pyelonephritis. Pulmonary embolism, myocardial injury, and stress ulcer occur frequently.

Direct causes of death from tetanus include: asphyxia, exhaustion, and medullary failure.[17] Firor suggested that tetanus toxin or some metabolite might have a direct effect on the medulla.[24] Baker noted swelling and perinuclear chromatolysis of nerve cells of the cortex and brain stem, and perivascular demyelination and gliosis near the nucleus of the vagus nerve in a series of patients who died from tetanus.[3,25] Montgomery also concluded that direct action of tetanus toxin or some metabolite on the medulla may be responsible for death of some patients.[6] Death from tetanus may result from tetanus itself as well as from second complications. However, medullary failure may be reversible if efficient ventilation can be maintained.[26]

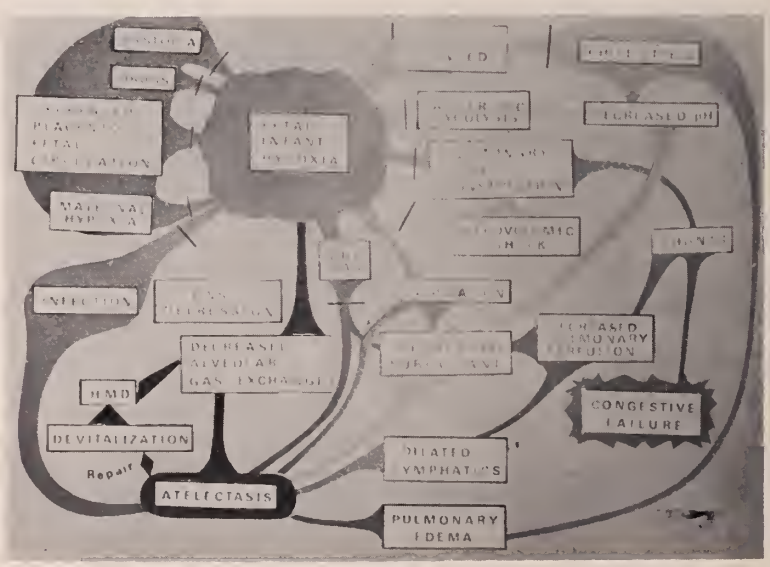
Respiratory Distress Syndrome

Preventive Aspects

MARTHA BURKE-STRICKLAND, M.D.

PREVENTION OF THE respiratory distress syndrome depends first on preventing prematurity and second on perinatal intensive care of all infants at risk. Such intensive care should begin in the labor room and continue from the delivery room to the newborn intensive care unit.[1]



The obstetrician, pediatrician, and anesthesiologist should work together as a team, but the primary responsibility should be the pediatrician's. He should be trained for fulfilling this role on the team. The Table lists some of the conditions known to produce infants at risk. When one of these conditions is identified in an expectant mother her physician should plan for the baby to be delivered in a perinatal center.[2,3] The pediatrician should be informed and kept posted on the progress of the pregnancy. When labor begins all members of the perinatal team should be notified.

The pediatrician should keep informed concerning the infant's condition during labor, be present at the delivery and be responsible for resuscitation of the infant immediately after delivery.

The Figure is a graphic representation of the production and consequences of fetal or neonatal hypoxia. The dotted lines crossing pathways of involvement represent points at which intervention by the team should improve the outcome for the infant.

Presented at the Minnesota Chapter of the American Academy of Pediatrics September 24, 1970.

Dr. Strickland is Assistant Professor of Pediatrics, University of Minnesota and Director of Newborn Services, Hennepin County General Hospital, Minneapolis.

Figure

Pre-Delivery Concerns for the Fetus

Maternal Hypoxia

Maternal hypoxia causes fetal hypoxia. As long as the materno-fetal circulation is intact, the fetal hypoxia can be alleviated by giving the mother 100% oxygen.[5,6]

Most anesthetic and sedative drugs cross the placenta. Some i.e., magnesium sulfate, barbiturates, carbocaine and Nisental have a direct central-nervous-system depressing effect on the fetus.[7,8,9] Bradycardia may be noted before delivery but acid-base balance is usually maintained until the cord is cut. In some infants a mild to moderate fetal acidosis may develop.[10,11] Infants with a diminished respiratory drive may not breath enough to maintain a normal pH, pO_2, and pCO_2. Anesthesia and sedative drugs should not be used unless absolutely necessary. When they must be used, then anticipatory assistance of ventilation must be given immediately after delivery and continued until the infant breathes well on his own. Concomitant monitoring of pH and blood gases is necessary.

On rare occasions, magnesium sulfate levels in the infant may be high enough to require exchange transfusions.[12,13] To reduce the assisted ventilation time required for an infant depressed by Nisental or other narcotics, 0.25 mg. Lorfan may be given.[9]

Decreased Placento-Fetal Circulation

Factors which decrease placental circulation affect the quality of the blood supply to the fetus. Monitoring of the fetus and anticipatory care are mandatory in all abnormal circumstances.

Maternal hypertension (toxemia) causes arteriolar alteration with decreased placental perfusion.[14,15] Uncontrolled for long periods of time, it results not only in hypoxia, but in diminished transfer of nutrients to the fetus. The resulting small-for-dates infant with chronic hypoxia is more vulnerable to the extra stress of delivery.[16,17] Intensive prenatal care and control of hypertension markedly reduce the infant morbidity and mortality.[18]

Maternal hypotension is usually an acute episode from blood loss, dehydration, infection, or local anesthestic agents.[8] Effective treatment depends on re-expansion of maternal circulating volume. Lowering the head and elevating the limbs may be helpful when the problem arises with spinal anesthesia.[8,9] Vasoconstrictors may improve the mother's blood pressure, but they may worsen placental profusion.[19]

Compression of the pelvic vessels can occur with prolonged positioning of the mother on her back during labor and delivery. This can be minimized by repositioning the mother and shortening the time she is on her back.[8,20] When compression of the vessels cannot be circumvented, then fetal hypovolemia and hypoxia should be anticipated and corrected immediately upon delivery.

Abruption of the placenta results in interruption of maternal-fetal exchange. The hemorrhage brings about hypovolemia and anemia and may add the extra complication of defibrination syndrome.[21] Base line fibrinogen level and platelet count should be obtained on the infant as soon as it is born, and these should be re-assayed every six hours for 24 hours or at any time the infant is symptomatic. When the prothrombin-time is greater than 2½ times the control, partial thromboplastin time greater than two minutes, fibrinogen level less than 0.05%, platelets less than 75,000, the infant should be given intravenous heparin 100 units/kg. Clotting studies should be repeated every four hours and additional doses of heparin should be continued every four hours (50u/kg) until factors are back to normal—usually within 48 hours.

Compression of the umbilical cord may result from knots in the cord, a nuchal cord or entrapment of the cord between fetal parts and the pelvis or the contracting uterus. Compression of the umbilical cord usually produces an acute hypoxia in the fetus from which the fetus recovers promptly with stimulation and assisted ventilation unless a prolonged second stage allows chronic hypoxia to develop.[8,22] Forceps delivery or interruption of labor may be indicated.[17]

Hypertonicity of the uterus during labor is best detected by monitoring of uterine contractions

TABLE

Conditions Associated with High Risk for the Infant

Habitual perinatal death	Fetal bradycardia
Maternal diabetes	Multiple births
Pre-eclampsia	Placenta previa
Evidence for intrauterine growth retardation	Cephalo-pelvic disproportion
Elderly primipara	Breech presentation
Rh sensitization	Abruptio placenta
Maternal narcotic addiction	C-section
Prolonged gestation	Polyhydramnios
Prolonged rupture of membranes	Oligohydramnios
Last trimester infection	Maternal thyrotoxicosis
	Rapid succession and pregnancies

with an intrauterine catheter and transducer.[23] Problems created by hypertonicity can be relieved by stopping labor and doing an emergency C-section.

Fetal Monitoring

Monitoring is used to follow the condition or response of the fetus to stressful intrauterine conditions. Several methods are useful.

Amnioscopy

Whenever chronic hypoxia is suspected in the last six weeks of pregnancy, direct examination of the amniotic fluid may be done as often as every other day. Variation from the normal clear or milky fluid may indicate imminent danger to the fetus.[24]

Amniocentesis

Direct samples of amniotic fluid may be obtained as early as 20 weeks gestation and thereafter to monitor excess bilirubin metabolites resulting from Rh sensitization. Measurement of estriol excretion in the amniotic fluid and analysis for creatinine levels may be used to determine gestational age for elective induction of labor or C-section.[25] Amniotic fluid cell analysis for inborn errors of metabolism and for chromosomal abnormalities is still used only as a research tool.

Since this was presented the use of Amniocentesis to determine lecithin—sphingomyelin ratios in the amniotic fluid has become very important in assessing fetal age. As lungs mature in utero, more lecithin is produced. When the lungs are mature enough to support life with less risk of respiratory distress syndrome the ratio is greater than 1.5 to 1. The infant will be safer if the ratio is 2:1. This is helpful in setting a time for elective C-Sections to insure that the infant is not delivered prematurely.*

Fetal Heart Rate

In assessing fetal heart rate, patterns are more important than range. Deviation from a base line and timing in relation to uterine contraction are important. Therefore, fetal heart rate and uterine contractions should be recorded simultaneously.

Three major patterns have been described: (a) early deceleration (Hon) or Type I dips (Caldeyro-Barcia) in which an early onset of bradycardia coincides with beginning uterine contractions. This type is thought to be due to head compression. No fetal pH or blood gas changes occur. The effect is altered by atropine.

(b) Late deceleration (Hon) or Type II dips (Caldeyro-Barcia) in which a bradycardia begins late in the uterine contraction. It is only partially modified by atropine, is accompanied by fetal acidosis, and is thought to be due to utero-placental insufficiency. If Type II dips appear and persist, it is recommended that labor be interrupted and an emergency C-section performed.

(c) Variable deceleration (Hon) occurs at variable times during uterine contractions. This is thought to be caused by umbilical cord compression. It is markedly altered by changes in maternal position or fetal manipulation; it is not associated with fetal acidosis unless the episodes of deceleration are frequent and prolonged.[22,27]

Scalp Blood Sampling

As soon as cervical dilatation and rupture of the membranes permit access to the fetal scalp, blood sampling can begin for the fetus who shows other signs of distress.[24,28] Capillary blood from the scalp has been proved to be a reliable sampling for determining status of the fetus.[28,29] A fetal pH less than 7.25 is generally accepted as a danger signal. pH is reliable as an indicator of fetal distress only when considered in context with other maternal-fetal parameters under observation.

Passage of meconium, type II dips, and fetal acidosis represent a level of hypoxia that demands intervention for the fetus.[22,24,27,30] The type of intervention will depend on the stage of labor and on the presenting conditions causing the distress.

Post-Delivery Infant Care

For anticipatory care of the newborn at risk, the pediatrician should be on hand in the delivery room when the delivery starts. All instruments and supplies for handling any emergency should be checked and ready for instant use even though they may not be used, because the time saved when they are needed may make the difference between a baby who survives adequately and one who survives with neurological damage.

The basic concepts of care can be summarized as follows:

Avoid "chill stress" of the infant.

Establish effective ventilation within one minute if possible. If no spontaneous respiratory effort is made by the baby, do not wait for the one-minute Apgar to tell you the infant needs help. Clear the airway and assist breathing by mask. Continue for 30 seconds if this is ventilating the chest, but if

*Whitfield, C R, Chan, W H, Sproule, W B & Stewart, A D, Amniotic Fluid Lecithin: Sphingomyelin Ratio and Fetal Lung Development. Brit Med J 303:85, 1972.

here are still no spontaneous respiratory movements, then intubate, use suction, and continue assistance with a mechanical ventilator as long as needed.

Correct metabolic acidosis immediately. Increasing the pO_2 and correcting the pH will relieve the pulmonary vasoconstriction.[31,32,33] Early correction of pH may also protect surfactant generation in the alveoli.[34] This can be done through the umbilical vein catheter by administration of a few cubic centimeters of solution containing 1 mEq/cc of $NaHCO_3$. One mEq/kg is given over a three to five-minute period. Further bicarbonate therapy is based on response of the infant and reported values for specimens drawn.

Begin therapy for hypovolemic shock[35] if the central venous pressure is less than 3 cm. H_2O, and the blood pressure is less than 20 mmHg. Give isotonic serum albumin intravenously at the rate of one gram/kg. Keep in mind that the sodium given for acidosis also acts as a volume expander; it has an osmotic potential for 7.2 cc water.[36] As the circulating osmolality is acutely increased, water will be drawn into the circulation in a matter of minutes. Redistribution of ions across the tissues may take several hours.

Keep handling to a minimum. The autonomic nervous system of the infant is in a state of siege. This is true of any newborn trying to adjust to an input of stimuli from many new sources. The fewer unnecessary stimuli he has to cope with, the sooner stability will be reached.[37,38] Every extra handling increases the energy demand for oxygen and if the infant's lungs are already behind in meeting need, extra calls for O_2 that can't be delivered only increase the metabolic deficit.

Supply the infant with energy. The high-risk infant may already have exhausted glycogen stores by the time delivery is completed. Continuing intravenous therapy with 10% glucose solution minimizes the chance of hypoglycemic shock as well as respiratory lag from fatigue.[39]

Use only humidified gases for assisted ventilation. Use of oxygen enriched air (30-35%) will suffice most of the time. Do not use 100% O_2 as it may actually "burn" the lungs as well as increase atelectasis; 100% O_2 displaces the inert N_2 gas in the residual functional volume of the lung. When the O_2 is absorbed into the perfusing circulation, the alveoli collapse at the end of expiration.[41]

Look for heart failure, and support as necessary although not every baby with hypoxia nor every baby with respiratory distress syndrome will have heart failure. A baby with a gallop rhythm and a liver down to the pelvic brim is probably in failure. One half the digitalizing dose of Lanoxin (0.04 mg/kg.) intravenously, will bring improvement within fifteen minutes. Cardiac failure does not preclude the use of $NaHCO_3$ for correction of acidosis, but the bicarbonate solution must be given more cautiously. The infant in failure will usually have a high central venous pressure (greater than 10cm H_2O) and variable blood pressure. Until the heart failure is corrected, no expanding fluids are needed, so the intravenous canula is kept open at 0.5 cc/hr for medications only. This degree of control can be achieved with a Harvard constant infusion pump.

Move with dispatch. Do the before-mentioned things in the delivery room. Time is of the essence if these therapeutic measures are to be preventive.

Transport only after stabilized. When the initial support measures are completed and the infant begins to stabilize, he may then be transported to an intensive care nursery for continued monitoring and therapy. Transport should be accomplished without disruption of the measures already described. A skilled attendant must accompany the infant whether the trip is to a unit across the hall or across town.

Pancreatic Scanning

Blind Review by Multiple Observers

DOUGLAS B. McGILL, M.D., HEINZ W. WAHNER, M.D. and
W. NEWLON TAUXE, M.D.*

MANY RECENT COMMUNICATIONS express some ambivalence about the value of pancreatic scanning. The initial enthusiasm in the early 1960's was modified by the later experience of physicians who found that pancreatic images were difficult to recognize and sometimes nonexistent, even when the pancreas subsequently was found to be normal.[1-11] Review of many reports suggests that the scan diagnosis often was made with knowledge of significant clinical information. Photographs emphasize classic examples.[5,8,10,12] The physician is most in need of help when there are no positive findings and a decision for or against surgical exploration must be made. There are few reports of blind reviews of pancreatic scans.[2,8] Therefore we undertook a study of scan interpretation by five observers with varied backgrounds and interests. The accuracy of each observer in detecting the presence of pancreatic disease and the agreement among them were assessed.

Material and Methods

Five observers reviewed selenium-75 scans of the pancreas in 71 patients, without prior knowledge of other findings in the cases. The scanning was performed by conventional techniques[13,14] after injection of 200 μCi of selenomethionine from two suppliers (Squibb Laboratories and Amersham/Searle). Sixty-seven ^{131}I-labeled Rose Bengal liver scans were available, permitting electronic subtraction in 32 and visual subtraction in all.[13,15,16] Cancer or pancreatitis was subsequently confirmed in 19 of 44 abdominal explorations or autopsies. A clinical diagnosis of normal pancreas was made in 21 cases and mild pancreatitis, in six. Adequate follow-up data were obtained in most of the normal patients to eliminate the possibility of carcinoma.

The observers included a gastroenterologist, three laboratory physicians, and a nuclear medicine technologist. All had experience with scanning procedures. The coded scans were presented randomly. The pancreatic image was judged to be indeterminate, normal, absent, or abnormal, based on decrease in count rate, absence of an image, or apparent filling defects. The correctness of the response was determined without regard to location of the lesion within the pancreas, since precise localization is beyond the limits of this technique in most instances. Each observer recorded his findings for the 32 electronically sub-

acted scans.

Results

There was considerable variation among observers. Table 1 shows several representative patterns. Each observer consistently tended to overinterpret or underinterpret abnormalities. Zero to 17% of the unsubtracted scans and 0 to 3% of the subtracted scans were recorded as indeterminate. Agreement with the final or correct diagnosis ranged from 68% for observer 1 to 40% for observer 4 with scans read by visual subtraction (Table 2). The agreement was not significantly better with electronic subtraction scan results in the entire group were the same as in the surgically proved cases.

A well-defined outline (Figures 1 and 2) recognized by three or more observers was highly predictive of normality (Table 3). Other positive correlations could not be defined. Although an absent pancreas (Figures 3 and 4) was taken as evidence of an abnormality in calculating the accuracy of response, the finding of an absent pancreas has no predictive value and such a scan cannot be interpreted.

Discussion

Pancreatic scans are imprecise. Some of the scans were technically superior to others for reasons which were not evident; the same methods were used throughout.

There was considerable variation among observers in our study. Observer 1 tended to view wide differences in shape and density of the pancreas as normal; this probably accounts for his greater accuracy. Observer 4 consistently over-reported abnormalities. Of interest is the accuracy of observer 5 who chose not to record any scans as indeterminate. Had this been done, with the elimination of some borderline scans (Figures 5, 6 and 7), his results, and indeed all results, would have been better. Acceptance of this limitation will decrease the element of guesswork.

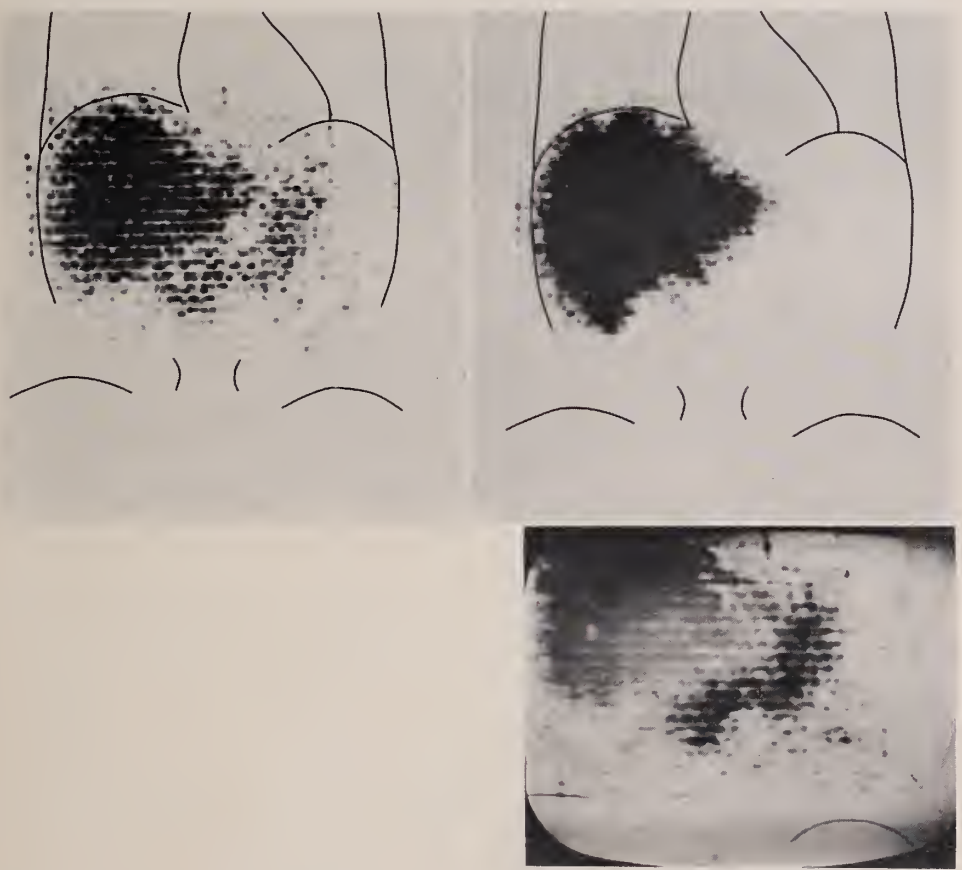

Fig. 1—*Upper,* Classically normal isotope pancreatic scans. Organ is sigmoid in shape, separate from liver. *Left,* Selenomethionine. (From McGill DB, Tauxe WN: Radioisotope scanning of the pancreas. Med Clin North Am 54:881-888, 1970. By permission of W. B. Saunders Company.) *Right,* ^{131}I-labeled Rose Bengal, *Lower,* Subtraction analysis is somewhat superfluous here but demonstrates technique.

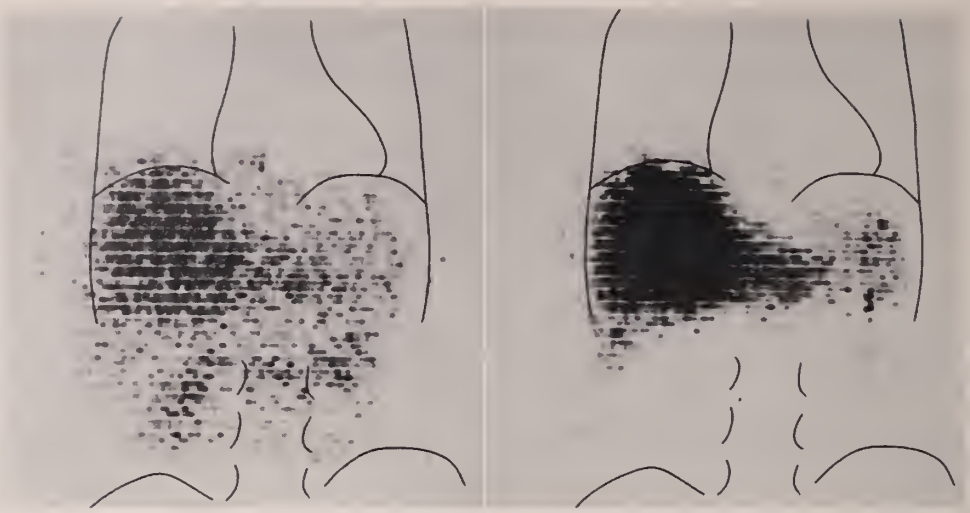

Fig. 2—Normal pancreas (proved surgically), but image is not as dense as in Figure 1. *Left,* Selenomethionine. (From McGill DB, Tauxe WN: Radioisotope scanning of the pancreas. Med Clin North Amer 54:881-888, 1970. By permission of W. B. Saunders Company.) *Right,* ^{131}I-labeled Rose Bengal.

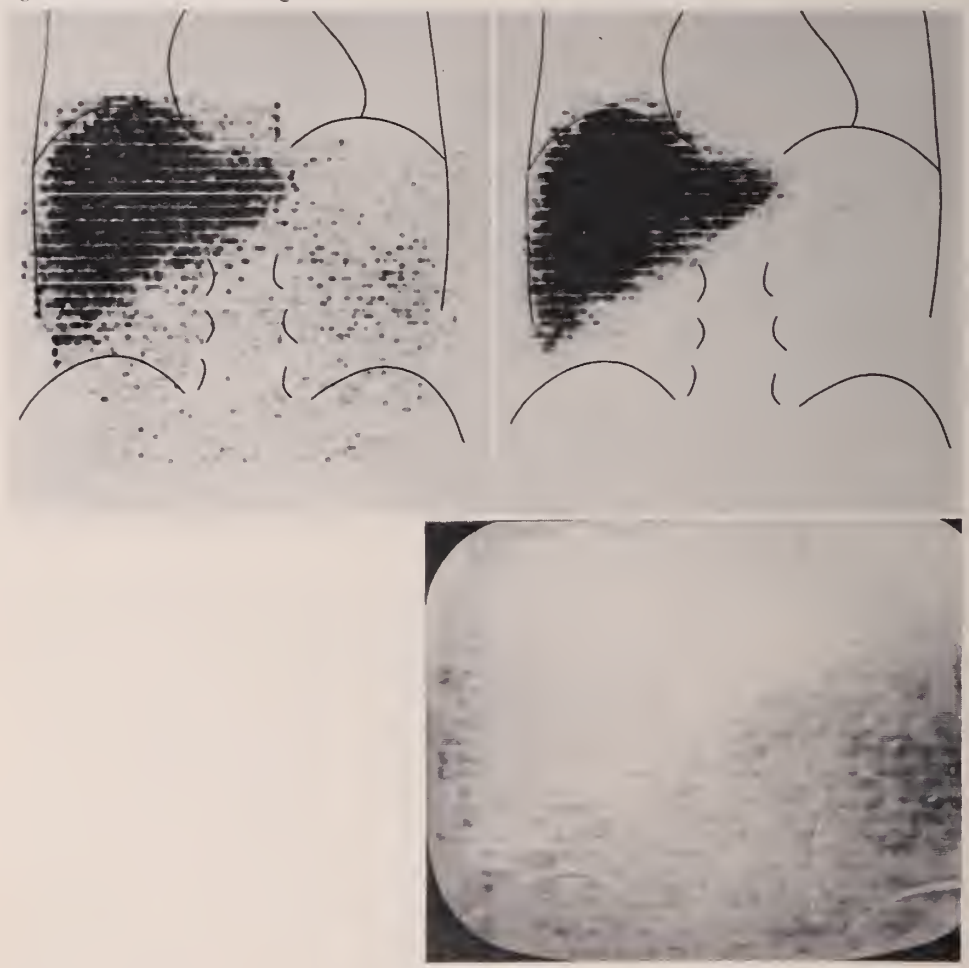

Fig. 3—*Upper,* No pancreatic image can be detected visually. *Left,* Selenomethionine. *Right,* ^{131}I-labeled Rose Bengal. *Lower,* Subtraction scan shows no pancreatic uptake, and operation demonstrated carcinoma. (From McGill DB, Tauxe WN: Radioisotope scanning of the pancreas. Med Clin North Amer 54:881-888, 1970. By permission of W. B. Saunders Company.)

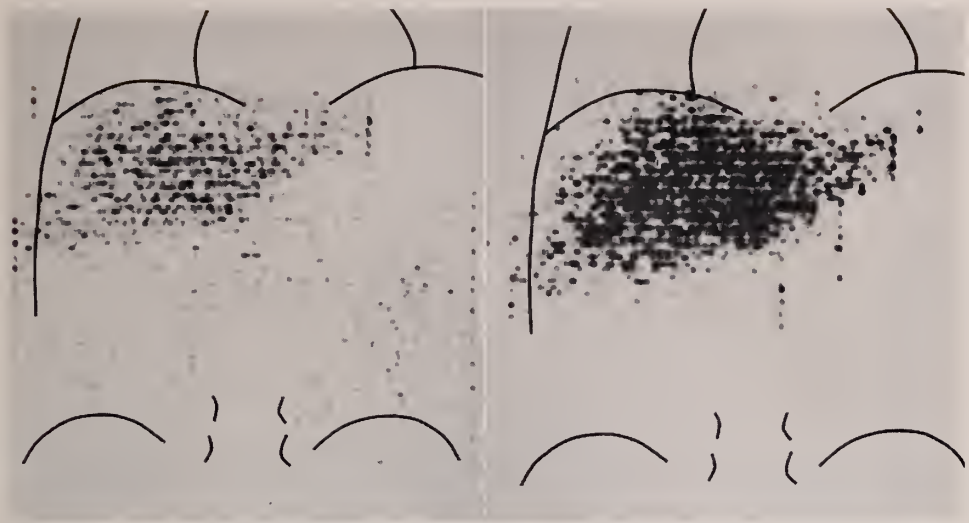

Fig. 4—No pancreatic image can be recognized visually. However, this pancreas proved to be normal. *Left,* Selenomethionine. *Right,* ^{131}I-labeled Rose Bengal.

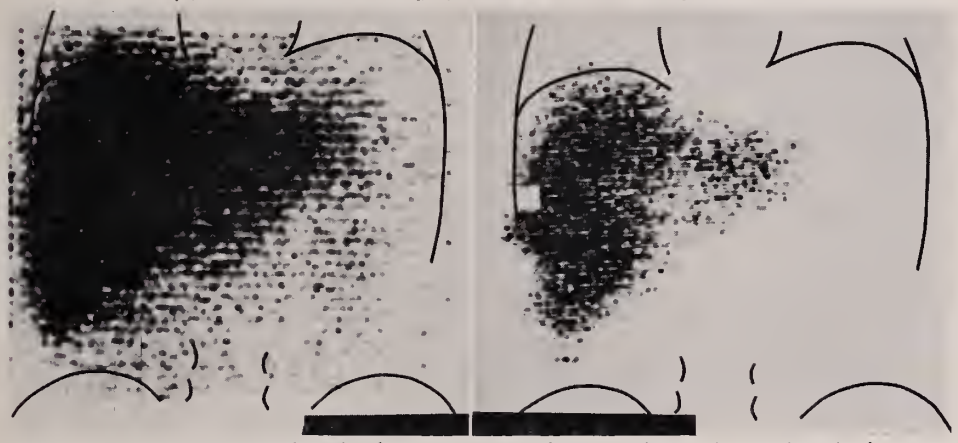

Fig. 5—Three observers found this scan to be uninterpretable and two thought it normal. Operation revealed large carcinoma in head of gland. In retrospect, perhaps the evidence is here but the element of guesswork is obvious. *Left,* Selenomethionine. *Right,* ^{131}I-labeled Rose Bengal.

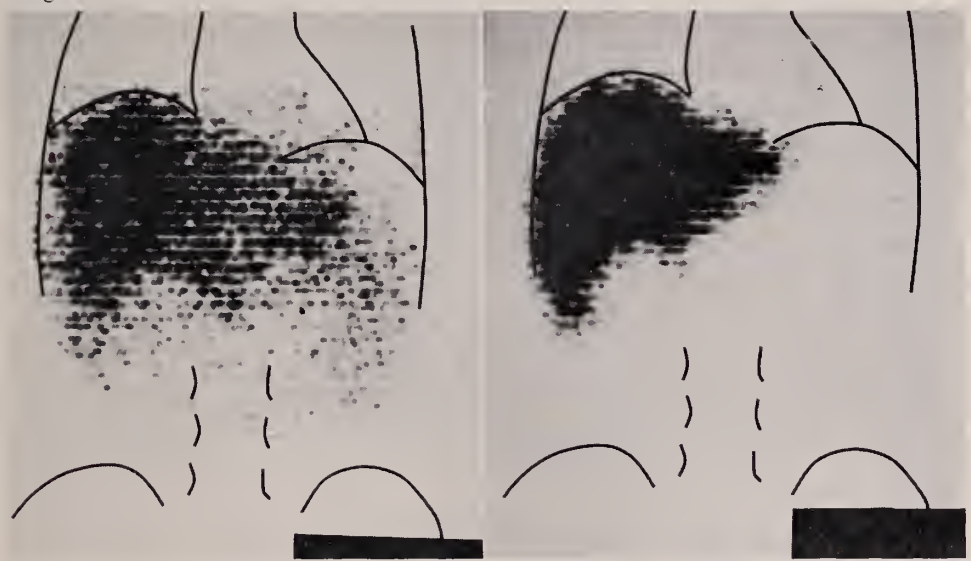

Fig. 6—One might imagine abnormalities in image, as three of five observers did in this review, but pancreas proved to be normal at operation. Subtraction scan (not shown) was similarly misleading. *Left,* Selenomethionine. *Right,* ^{131}I-labeled Rose Bengal.

At present we are at an impasse, awaiting the development of material which will be taken up selectively by pancreatic tissue or of techniques to define the normal gland better. Extrapancreatic uptake, failure of the normal pancreas to visualize, and apparent decrease in uptake with resulting vague filling defects contribute to frequent false-positive scans. Subtraction techniques often eliminate the problem of the overlying liver, but our data to date suggest that electronic subtraction only occasionally offers greater benefit than visual subtraction. Computer analysis and scinticamera techniques, currently undergoing evaluation, should be substantial improvements.

A test which offers a potential accuracy of 6[illegible] to 90% on attempted readings in difficult clinical situations may be of some value if the test can be performed with little or no risk and at minimal cost. The radiation risk of a pancreatic scan is probably negligible, and the expense can be decreased. Occasional scans will reveal classic findings (Figure 8) which should help the clinician. The success of these scans tends to be buried in our overall meager results.

See page 804 for References 1-16.

Fig. 7—Extrapancreatic uptake and adjacent liver make pancreatic image difficult to outline. This 67-year-old woman was recovering from mild pancreatitis. One should probably record this image as normal or indeterminate and wonder about possibility of filling defect in body. *Left,* Selenomethionine. *Right,* ^{131}I-labeled Rose Bengal.

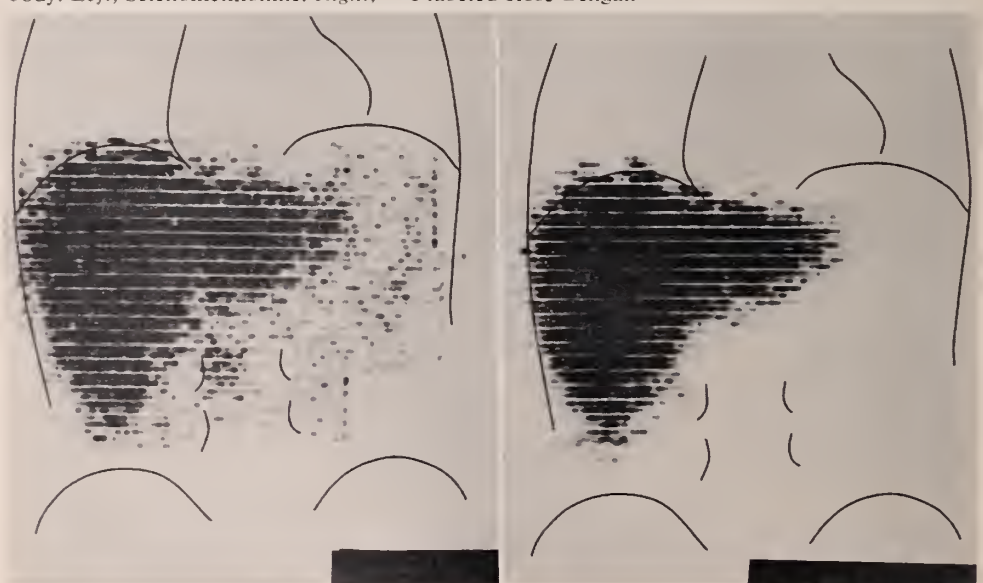

Fig. 8—This and scans in Figures 1 and 2 justify further efforts to refine technique. Head of pancreas is evident but body and tail are cold. At operation, carcinoma involving predicted areas was found. *Left,* Selenomethionine. *Right,* ^{131}I-labeled Rose Bengal. (From McGill DB, Tauxe WN: Radioisotope scanning of the pancreas. Adreno-Cortical Adenoma With Malignant Hypertension

Report of One Case

RAFAEL CARMENA, M.D. AND JOHN I. COE, M.D.

THE HYPERTENSION SEEN in patients with primary aldosteronism is usually of moderate severity.[1] Only a few cases of well documented primary aldosteronism associated with malignant hypertension have been reported.[2-5] We have studied a patient with malignant hypertension who had normal aldosterone values in urine and normal-appearing adrenal glands at exploratory laparotomy. He died after a nine-year course of what was considered to be essential malignant hypertension. At autopsy a cortical adenoma measuring 1 cm. in diameter was found in the right adrenal gland. Evidence is presented which suggests that this may have been a primary aldosteronoma.

Case Report

A 30-year-old man was found to have hypertension in 1960 in a pre-employment examination. He was asymptomatic until 1962 when he consulted a physician because of nervousness and headaches. He was again found to have an elevated blood pressure, and was treated with antihypertensive medications. No family history was available since the patient was adopted. At 35 years of age he was admitted to another hospital complaining of shortness of breath on exertion and ankle edema. The physical examination revealed a slender Caucasian individual with a blood pressure of 196/150. The fundoscopic examination showed a grade II Keith Wagner hypertensive retinopathy. The pulses were equal in all extremities. Auscultation of the heart revealed a regular rhythm and no murmurs. The point of maximal impulse was at the fifth intercostal space in the anterior axillary line. There were bilateral pulmonary basilar rales. The liver was felt four cm. below the right costal margin. No bruit was heard over the abdomen. The lower extremities had 3+ pitting edema.

The laboratory studies included normal complete blood counts; serum sodium, 142 mEq/L, potassium four mEq/L, chlorides 96 mEq/L, and carbon dioxide content 34 mEq/L. The urine gave a 3+ test for albumin and contained small numbers of red blood cells. The fasting blood glucose was 92 mg%. The blood urea nitrogen was 30 mg% but subsequently fell to 19 mg%; the serum creatinine 1.9 mg% and the creatinine clearance 115 ml/min. An electrocardiogram showed first degree atrioventricular block, left axis deviation and left ventricular hypertrophy. The chest Xray showed globular enlargement of the heart with moderate pulmonary edema. Intravenous pyelogram and radioisotope renogram demonstrated bilaterally reduced renal function. A renal arteriogram suggested a deformity of the left renal artery and a selective left renal arteriogram showed a "somewhat small" superior left renal artery with possible stenosis. A 24-hour urine collection showed normal VMA and aldosterone values; no renin studies were done. Because of the possibility of renal artery stenosis an exploratory laparotomy was performed. There was no pressure gradient between the left renal artery and the aorta. Both adrenal glands were palpated and thought to be normal. The patient was diagnosed as having essential hypertension and was discharged on digitalis, reserpine, guanethidine and hydrochlorothiazide.

During the next four years he was followed at the outpatient clinic in Hennepin County General Hospital, and his blood pressure fluctuated between 130/80 and 210/130. He was able to work only five hours per day as he tired easily and had frequent headaches. He developed severe hypertensive retinopathy, including papilledema. His medications included digitalis, hydralazine, methyl-dopa, guanethidine, K-triplex and intermittent thiazides. He complained of persistent leg cramps which seemed to be exacerbated by thiazide diuretics and relieved to some extent by the administration of potassium salts. He complained also of nocturia (urine volume three times greater during the night than day) and was constantly thirsty. He was free of edema during this time. His urine had a pH of eight, specific gravity 1.021 and contained 1+ protein. The creatinine clearance was 150 ml/min. and the blood urea nitrogen 22 mg%. Determinations of serum electrolytes found the sodium ranging from 143 to 148 mEq/L, potassium from 2.4 to 4.3 mEq/L, chlorides from 93 to 105 mEq/L and the carbon dioxide content from 28 to 38 mEq/L. Urinary electrolytes, with the patient on a 2 Gm. salt diet and off thiazides, were sodium 55 mEq/L and potassium 81 mEq/L. His plasma volume (determined with radioiodinated serum albumin) was 3850 ml, +114% of the predicted value.

Dr. Carmena is a Medical Resident at Hennepin County General Hospital.

Dr. Coe is Chief of Pathology, Hennepin County General Hospital, Minneapolis.

From the Department of Internal Medicine and Pathology, Hennepin County General Hospital, Minneapolis, Minnesota.

In March 1969, the serum sodium was 145 mEq/L, potassium 2.6 mEq/L, chlorides 95 mEq/L, carbon dioxide content 38 mEq/L and the blood pressure 190/110. The patient had been off thiazide diuretics for several weeks. All medications but digitalis were discontinued and he was started on 6 Gm. sodium chloride and 600 mg. of Spironolactone per day. Seven days later the serum sodium was 142 mEq/L, potassium 3.6 mEq/L, chlorides 103 mEq/L and carbon dioxide content 26 mEq/L. Two weeks later the blood pressure was stable about 150/80. There was no evidence of heart failure. The possibility of the patient's having primary aldosteronism was considered in spite of his previously negative workup. He was admitted for another study. On the second hospital day the patient developed severe pulmonary edema, intractable heart failure and expired in cardiogenic shock.

Autopsy

Postmortem examination revealed severe heart disease, congestive failure, and an adrenal cortical adenoma on the left with mild cortical atrophy of the right adrenal.

The heart weighed 900 grams showing marked left ventricular hypertrophy consistent with hypertensive cardiomegaly. Valves were normal. The coronary arteries revealed moderate sclerosis and there was extensive myocardial fibrosis with an area in the anterolateral wall of the left ventricle representing a healed subendocardial infarct.

The liver and spleen showed passive congestion, while the lungs were heavy and edematous. The left and right kidneys weighed 190 and 170 grams respectively. Their surfaces were mottled and pitted.

The left adrenal gland contained a sharply circumscribed bright yellow adenoma 1.2 cm. in diameter distending the medullary portion of the gland. The right adrenal was smaller than normal with the cortex thin and atrophic.

Sections of the adrenal cortical adenoma showed a circumscribed tumor appearing to arise from the zona reticularis which was composed of large clear cells in which the nuclei varied in size with a few large dark nuclei being evident (Figure 1). No mitotic activity was seen. Portions of the adenoma fixed in Zenker's solution showed no dichromate reduction.

The right adrenal showed mild thinning of the

Fig. 1—Adrenal cortical adenoma (X40). The cells of the adenoma were large with clear cytoplasm and varying sized dark nuclei.

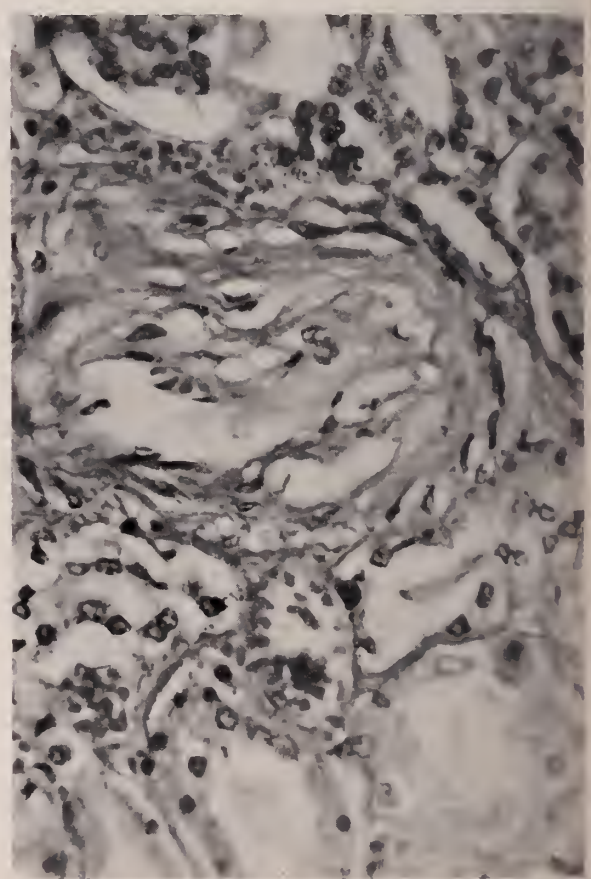

Fig. 2—Renal arteriole (X415). There is endothelial proliferation, splitting of fibers and edema of the vessel wall.

cortex due to atrophy of the zona glomerulosa but was otherwise histologically normal.

The kidneys revealed congested but essentially normal glomeruli and tubules. Large blood vessels revealed only mild medial sclerosis. In contrast small muscular arteries and arterioles all showed medial and intimal proliferation. This was most apparent in the intima where splitting of fibers and edema greatly narrowed the lumina (Figure 2). Many arterioles revealed occlusive intimal proliferation although no fibrinoid degeneration of vessel walls was noted. The histology was felt to be consistent with that found in malignant hypertension.

Discussion

The case presented is that of a 39-year-old man with malignant hypertension and an adreno-cortical adenoma of the right adrenal gland. A study of the patient's hypertension done at another hospital in 1964 was non-revealing, including laboratory studies of the serum electrolytes, urine studies for aldosterone and vanyl-mandelic-acid, and abdominal angiography. A laparotomy disclosed normal renal arteries and adrenal glands.

It is surmised that the adrenal tumor found at autopsy was active as evidenced by atrophy of the zona glomerulosa in the contralateral adrenal cortex. This finding has been reported by others and presented as evidence of functionally active adrenal tumor.[6]

He had a persistent hypernatremia and hypokalemic alkalosis that was accompanied by severe muscle weakness even when thiazide diuretics were discontinued. The patient had responded to the administration of spironolactone with correction of the electrolyte imbalance and significant fall of the blood pressure to normal diastolic values. It has been suggested[7-9] that this type of response is characteristic of primary aldosteronism.

The patient complained of nocturia and polydipsia while maintaining adequate renal function. He had minimal or no edema for the last four years of his life. The hypernatremia, hypokalemia, hypochloremia and elevated plasma carbon dioxide content became normal by the administration of spironolactone, with a decrease to normal of the diastolic blood pressure. These data suggest that the adrenal tumor may have been a primary aldosteronoma.[9]

Sutherland et al.[10] have described two patients with benign hypertension, potassium depletion, increased aldosterone secretion, raised plasma volume, suppressed plasma renin activity and intermittent elevation of 17-ketosteroids and 17 hydroxicorticoids in the urine. These abnormalities disappeared when the patients were given dexamethasone. In one of the patients, large doses of spironolactone corrected the electrolyte imbalance and brought the blood pressure to normal levels. This patient had the adrenal glands explored and multiple, small nodules (0.1-0.4 cm. in diameter) were found in one of the glands. Patients with primary aldosteronism do not respond to the administration of dexamethasone and usually have normal urinary 17-KS and 17-OHCS. The possibility of our patient having a condition similar to the one described by Sutherland cannot be totally excluded.

The question arises whether the patient had malignant hypertension associated with secondary aldosteronism or whether the adreno-cortical adenoma had produced primary aldosteronism with malignant hypertension.

Malignant hypertension is almost universally associated with secondary aldosteronism.[11] Characteristically, one finds low or normal serum sodium levels, hypokalemia and elevated plasma bicarbonate content. A normal or elevated serum sodium, as found in our patient, is rare in essential hypertension.[12,13] The patient had an elevation of his plasma volume of +114% of his predicted value. Increases in plasma volume have been reported in patients with primary aldosteronism, while patients with essential hypertension or renal arterial lesions characteristically have normal to decreased plasma volumes.[13]

The administration of spironolactone to patients with secondary aldosteronism will correct the electrolyte imbalance but has little or no effect on the blood pressure levels.[9] In our patient, as in other patients with primary aldosteronism, administration of spironolactone corrected the electrolyte abnormalities and produced a significant drop in the blood pressure. Secondary aldosteronism is associated with bilateral adrenal hyperplasia, but not a unilateral adenoma. It is possible that the subject studied had a functioning adenoma of the right adrenal gland cortex with a clinical picture of primary aldosteronism.

The patient had a single determination of urine aldosterone that was reported normal. This fact does not necessarily exclude a functioning aldo-

steronoma since plasma and urine aldosterone concentrations may vary considerably in patients with primary aldosteronism.[14]

Until recently, the occurrence of malignant hypertension in patients with primary aldosteronism was considered extremely rare.[1] In 1963, Kaplan[2] reported the first patient with malignant hypertension with clinical and laboratory features of primary aldosteronism.

Brown et al.[3] described a case of adreno-cortical adenoma with hypertension and arteriolar fibrinoid lesions found at renal biopsy. del Greco et al.[4] reported a case of primary aldosteronism with malignant hypertension. The patient had papilledema, exudates and hemorrhage in the optic fundi. Microscopic examination of the kidneys showed mild arteriolar nephrosclerosis. Our case had an adreno-cortical adenoma and severe hypertension, with Grade V retinopathy and proliferative arteriolitis in the kidneys. Smithwick et al.[15] reported two patients who had a negative bilateral adrenal gland exploration because of hypertension and clinical aldosteronism and were later discovered to have a functioning, isolated cortical adenoma measuring two and 1.8 cm. in diameter respectively.

The case presented should serve as a reminder that a primary aldosterone-secreting tumor may precipitate malignant hypertension and one should consider such possibility when dealing with patients with both the benign and malignant type of hypertension. A single determination of urine aldosterone and a negative surgical exploration of the adrenal glands do not exclude the presence of a functioning adreno-cortical adenoma. Repeated urine aldosterone and plasma renin determinations might have been helpful.

Acknowledgments

The authors wish to express their appreciation to Dr. James Murphy for his helpful criticism of this paper.

Spontaneous Subarachnoid Hemorrhage

Initial Presentation of Brain Tumors

GAYLAN L. ROCKSWOLD, M.D. AND EDWARD L. SELJESKOG, M.D.

SUBARACHNOID HEMORRHAGE has many causes. This is well illustrated by Walton,[12] who in an excellent review article listed over 40 possible conditions which may produce subarachnoid hemorrhage. Despite this fact, in many physicians' minds subarachnoid hemorrhage is almost exclusively related to ruptured intracranial aneurysms. This is not without some justification, since the "Report on the cooperative study of intracranial aneurysms and acute subarachnoid hemorrhage"[7] found that 51% of subarachnoid hemorrhages are due to ruptured aneurysms. A significant percentage remains, however, due to other etiologies. Brain tumors are one such relatively unusual source of subarachnoid hemorrhage. This paper concerns the clinical problem of brain tumors presenting with subarachnoid hemorrhage.

In 1924, Symonds wrote the first systematic review of spontaneous subarachnoid hemorrhage.[11] He discussed tumors and cysts as a possible source of subarachnoid hemorrhage and presented two such cases. Over the next several years there were several published case reports of brain tumors presenting with subarachnoid hemorrhage; sometimes repeated and diffuse.[3,4,5,10]

In 1955, Glass and Abbott[6] reviewed the literature and found 41 cases of brain tumor presenting with the abrupt onset of subarachnoid hemorrhage, mimicking aneurysm. They added seven additional cases of their own. The exact number of hemorrhages could not be determined in all instances; but of 36 patients all but six had more than one hemorrhage. Of the 41 cases analyzed, 50% of the tumors were primary gliomas of the cerebrum with 12 of the 20 being malignant astrocytomas. Pituitary lesions, mainly adenomas, accounted for the second largest category, with 11 cases. The mechanism of hemorrhage was postulated to be the same as that for intraparenchymal hemorrhage into most malignant gliomas, i.e. vascular endothelial proliferation with resultant vessel occlusion, secondary necrosis and loss of vessel support, leading to hemorrhage. Signs and symptoms were those typical of subarachnoid hemorrhage of any cause, namely headache, nausea and/or vomiting, nuchal rigidity and altered consciousness.

The following case history emphasizes the diagnostic difficulties encountered when this situation presents.

Case Report

This 44-year-old man was admitted to the Minneapolis Veterans Administration Hospital on January 9, 1967, with a history of the sudden onset of severe left sided headache on January 3, 1967. This was accompanied by photophobia, nuchal rigidity, rather marked mental confusion, and disorientation. Historically the patient had had an identical episode about one month previously. These symptoms subsided spontaneously over a few hours, with the exception of mild personality change and a minimal degree of alexia. The patient sought no medical attention until after the second episode.

Examination

The patient was slightly confused and disorientated and had an obvious expressive and receptive aphasia. There was some degree of nuchal rigidity, but otherwise the general physical and neurological examinations were completely normal. A lumbar puncture demonstrated grossly bloody spinal fluid.

The initial impression of the examining surgeons was that of subarachnoid hemorrhage, likely secondary to an intracranial aneurysm along with a probable left temporal lobe hematoma. On January 10, 1967, bilateral carotid angiography revealed a large avascular lesion within the left temporal lobe. There was no demonstrable aneurysm, nor was there any evidence of vasospasm of the intracranial vessels. Similarily there was no evidence of "tumor stain."

Surgery

The following morning the patient was taken to the operating room where upon opening the dura the expected subarachnoid hemorrhage was noted. Additionally, much as anticipated, a rather large hematoma was encountered within the left temporal lobe. Following

See editorial, page 819.

evacuation of the hematoma, abnormal appearing tissue was encountered in the depths of the hematoma cavity. This was biopsied and frozen section confirmed the presence of malignant glial tumor. A modified temporal lobectomy was carried out.

Postoperative Course

Postoperatively the patient's prior aphasia and alexia cleared nearly totally. Permanent pathological specimens confirmed the tumor to be a glioblastoma multiform. The patient received a course of radiation therapy in the postoperative period and did reasonably well for eleven months. He then deteriorated, expiring on January 31, 1968.

Discussion

The "Report on the cooperative study of intracranial aneurysms and acute subarachnoid hemorrhage"[7] found the incidence of subarachnoid hemorrhage associated with brain tumors to be about two percent. However, if one limits the criteria to those in which the clinical onset is abrupt and thereby closely mimics subarachnoid hemorrhage for aneurysm, it is a relatively unusual event.

This case of a previously asymptomatic man with two typical attacks of subarachnoid hemorrhage emphasizes that subarachnoid hemorrhage is not an entity in itself. Although aneurysm is its most common cause, various other pathological processes must be considered, especially when angiography does not reveal an aneurysm, vascular malformation, or other obvious source for the hemorrhage. Under these circumstances a complete evaluation and thorough appraisal of the problem is indicated, since even benign lesions, such as meningiomas and pituitary adenomas have occasionally presented with typical signs of subarachnoid hemorrhage.[1,2,8,9]

Summary

We have reported a case of a previously asymptomatic man who presented with a picture typical of repeated acute subarachnoid hemorrhage. The presumed diagnosis was that of a ruptured aneurysm or cryptic vascular malformation, until the time of surgery, when in addition to the findings of a typical subarachnoid hemorrhage, a large malignant glial tumor of the left temporal lobe was then identified. This case emphasizes that aneurysms and vascular malformations are not the sole cause of acute subarachnoid hemorrhage or even repeated episodes of subarachnoid hemorrhage. Other possible etiologies must be especially sought when angiography fails to reveal an obvious source of hemorrhage.

Intravenous Lidocaine for Status Epilepticus

GILBERT WESTREICH, M.D. AND A. WILLIAM KNELLER, M.D.

THE DRUG OF CHOICE today for status epilepticus is probably intravenous diazepam.[1] It is effective and relatively nonsedating (in comparison to the barbiturates). Some clinicians prefer intravenous, rapidly acting barbiturates, or Dilantin. Paraldehyde is occasionally recommended. If all else fails, general anesthesia is recommended as a "last resort."

This is a report of the use of another anesthetic drug, intravenous lidocaine. Indications for the use of lidocaine are not limited to producing conduction block anesthesia. Bernhard,[2] following several reports of the effectiveness of local anesthetics in animals,[3] first reported the use of intravenous lidocaine in the treatment of humans with status epilepticus. This treatment with lidocaine has been documented in the medical literature and reference books.[4,5] The use of lidocaine is, however, not well known and most "emergency" manuals fail to mention lidocaine as a possible therapeutic agent.[6,7]

Case Report

The patient was a 45-year-old, 213 lb., white male who was admitted to hospital because of recurrent and frequent seizures. In 1944, the patient was in an auto accident in which he sustained a severe head injury and was unconscious for several days. Subsequently he had had recurrent major, minor and right-sided Jacksonian seizures. He was a chronic alcoholic and was said to have "Chronic Brain Syndrome." His anticonvulsant medication consisted of taking Dilantin (100 mg. t.i.d.) and phenobarbital (60 mg. t.i.d.) which he took regularly. He had had previous episodes of status which numbered about 10 and had always been promptly relieved by intravenous barbiturates (in recent years by intravenous diazepam). There was no recent history of infection or other drug ingestion, except for small doses (25 mg. t.i.d.) of Mellaril. He said (later) that he had been seizure free for about four years.

Recently he had been admitted to another hospital after at least two grand mal seizures and recurring focal Jacksonian seizures every 10 minutes. The physical exam revealed an obese, dazed, mildly dysarthric white male with nystagmus on lateral gaze. No paralysis was noted. Babinski signs were present bilaterally. The patient was treated with intravenous and intramuscular doses of diazepam (10 mg. IV, four times in 12 hours), intravenous Dilantin (500 mg.), phenobarbital (120 mg., IV) and magnesium sulfate (1 gram in each buttock). After two days of frequent seizures uncontrolled by the above medications, he was unimproved and nearly comatose. He was then transferred to the Minneapolis Veterans Hospital.

Physical Findings

After transfer, his vital signs were stable and normal. He was unresponsive and having Jacksonian type seizures that began on the right side of his face and spread to the right side of his body, without becoming generalized. His neck was supple and his eyes deviated conjugately to the right. There was no papilledema. Bleeding from the tongue was noted. He did not move his extremities on command. His reflexes were sluggish and there were no abnormal toe signs. The patient withdrew each extremity to painful stimulation.

Hospital Course

During the next two days the patient continued to have focal seizures every three to four minutes. Occasionally a period of 20 minutes would elapse between seizures, but consciousness was not regained between seizures. Twenty mg. of diazepam IV was given every hour times three. Paraldehyde per rectum (20 ml.), Dilantin (1 gram IV) and large doses of phenobarbital (100 mg. Q4h) were administered. His seizures, however, continued. He was subsequently intubated because of respiratory supression and steroids were given.

Laboratory Data

Routine laboratory work, including spinal puncture was unremarkable. There were 12 RBCs and 59 WBCs in the CSF after three days of status. A left carotid angiogram was normal. An electroencephalogram was done while he was in status and showed hemispheral assymetry with depression of the faster frequencies and amplitude with low voltage spikes and excessive, diffuse, slowing.

After the above measures failed to halt his continuous seizures, general anesthesia was considered. At the suggestion of one of the authors (A.W.K.) intravenous lidocaine was used. The patient was given 150 mg. of lidocaine IV and one gram of lidocaine in 250 cc of

Dr. Westreich is in the Neurology Service, Veterans Administration Hospital, Minneapolis, Minnesota.
Dr. Kneller is in the Anesthesiology Service, Veterans Administration Hospital, Minneapolis, Minnesota.

5% dextrose in water was dripped in over one hour. About five minutes after the IV bolus of lidocaine was given, the patient manifested one mild focal seizure. Following this, he was seizure free. He was subsequently given one more lidocaine drip (one gram in 250 cc of fluid) over the next six hours. The lidocaine was discontinued and the patient was maintained on Dilantin (100 mg. t.i.d.) and phenobarbital (30 mg. t.i.d.). He woke slowly over the next few days and developed pneumonia and asthmatic bronchitis which responded to appropriate treatment.

At the time of discharge from hospital, there were minimal signs of left cortical involvement. The patient was alert and the mental examination was within normal limits. The patient still insisted that he had been taking his medicines faithfully. He also denied an excessive use of alcohol. He said cheerfully when he left: 'I'll see you guys the next time I go into status."

Trade names: Dilantin—diphenylhydantoin sodium. Xylocaine—lidocaine.

Indications and Side Effects

Although intravenous diazepam is the drug of choice for status epilepticus, intravenous lidocaine may also be an effective agent when diazepam fails. Potential disadvantages of lidocaine are: (1) possible allergic reaction; (2) depression of the myocardium; and (3) paradoxically, seizures. (Why the drug should be effective in the control of status epilepticus, yet instigate seizures occasionally has not yet been fully explained).

Administration

We recommend the use of intravenous lidocaine in the following manner. First, as intravenous bolus of 1.5 mg/kg., followed by an IV drip of 10 mg/kg. in D5W run in over four to six hours. The drip may be repeated if necessary. The patient should be continuously monitored with EKG and probably would be best managed in an intensive care unit under the supervision of appropriately trained personnel. Naturally, possible inciting causes for the status such as brain abscess, subdural hematoma or other irritative lesions must be vigorously investigated.

Cover Painting

"Pleasant Lake"

Doctor Harry B. Clark tells us: "After World War One I settled in St. Cloud, where I was born, and engaged in general practice until about 13 years ago when I became a member of the St. Cloud Veterans Hospital staff, where I still am. I always wanted to paint, but like so many people, didn't believe I possibly could. About 20 years ago I tried copying a picture using one of my children's water color sets just to see what I could do. I liked it well enough and enjoyed doing it so much I just kept on. Later I added oil painting and recently have experimented with acrylics.

The painting itself is a lake near St. Cloud called Pleasant Lake. It is not how it looks today, with permanent homes all around it, but as it looked many years ago when there were only a few summer cottages and one of them mine. Mist must still form on the surface of the lake on chilly mornings, but I doubt if the blue herons still can be seen. That is one of the advantages of painting over photography, you can depict past, present or future and put in characters like blue herons that do not sit for photography."

Thymectomy

In Fulminating Myasthenia Gravis of Childhood

KENNETH F. SWAIMAN, M.D. AND RICHARD L. VARCO, M.D.

Following the neonatal period, the incidence of myasthenia gravis is very low until after five years of age.[1] Although neonatal persistent myasthenia gravis rarely embarrasses the bulbar muscles or muscles of respiration, myasthenia gravis appearing later in the first decade can be a cataclysmic affair.[2] After early years of controversy, punctuated by transatlantic debate, thymectomy has been accepted as a method of therapy which is frequently successful in young women without thymomas, who have had the disease for a short period of time.[2] Recently, it has been suggested that thymectomy has little value in the young child.[3] This is a report of a thymectomy performed on a 28-month-old myasthenic child that was life-saving.

Case Report

This male child was first admitted to the University of Minnesota Hospitals at age 22 months in January 1967 with a four week history of left eyelid ptosis and a one week history of "his eye turning out".

He had been in good health except for a short episode of pneumonia at age seven months. His mother did not have myasthenia and has not subsequently developed the disease. The general physical and neurological examination were normal with the exception of bilateral ptosis and left exotropia. He was given 1.0 mg of edrophonium chloride intravenously with marked improvement of both the ptosis and exotropia.

Thyroid function studies and blood electrolytes were normal. Chest Xray was normal. Electromyography (EMG) revealed no decrease in amplitude of action potentials during repetitive supramaximal stimulation of the ulnar nerve.

Therapy with oral neostigmine chloride was begun at a dose of 10 mg every four hours and increased to 15 mg every four hours. The ptosis and squint were improved and he was discharged on February 2, 1967.

His clinical course is charted in the Table. Briefly, he developed bulbar weakness which progressed rapidly in addition to the weakness of his extraocular muscles despite large doses of anticholinesterase drugs. (He was receiving pyridostigmine 60 mg every four hours and neostigmine 20 mg every two hours. Edrophonium chloride administration increased strength, but increased secretions also.) He had progressive difficulty swallowing and controlling his secretions. Right upper lobe atelectasis appeared. He had several episodes of apnea and bradycardia. In April of 1967, after an abrupt episode of apnea, a tracheostomy was performed. He became severely ill with pneumonitis, respiratory weakness in May of 1967 and became progressively worse. He underwent a thymectomy and gastrostomy on July 19. Microscopic examination of the thymus revealed simple hyperplasia. He had a stormy postoperative course primarily because of profound residual pneumonitis. He improved remarkably after the thymectomy and necessitated only small doses of anticholinesterase drugs to allow him to control his secretions and alleviate his ptosis and squint.

Attempts at removing the tracheostomy tube over the

TABLE
Clinical Course

	Clinical findings	Therapy
Jan/67	Ptosis Exotropia (age 22 months)	
Feb/67	Ptosis Exotropia	Neostigmine-p.o. (10-15 mg/q4h)
March/67	Increased Weakness Extraocular Muscles	Neostigmine-p.o. (20 mg/q4h)
April/67	Acute apnea Pneumonitis	Tracheostomy Neostigmine-p.o. (20 mg/q4h) Pyridostigmine-p.o. (60 mg q4h)

was primarily prolonged by difficulty of residential placement. He was discharged on February 2, 1969 on pyridostigmine bromide 25 mg every three hours, and atropine 0.1 mg every three hours which was needed to control nasopharyngeal secretions.

By March 1972, he gradually gained increasing use of his swallowing muscles and he has gained weight and presently attends public school. Supplemental feedings are still administered through his gastrostomy tube although he is able to handle increasingly larger amounts of liquids and solids orally. His tracheostomy was removed in February 1972. He receives pyridostigmine bromide 35 mg every four hours.

Comment

Keynes[2] initially reported that thymectomy was a successful means of managing myasthenia gravis when it appeared in a fulminating form in early childhood.[2] His youngest patient, age two and a half at time of thymectomy, was gravely ill at time of surgery and died postoperatively. Sutin and Hewitson[4] report a 25-month-old child with ocular muscle weakness alone, who responded to thymectomy. Although details are not given, Fonkalsrud and associates reported a two-and-a-half-year-old child who improved after thymectomy.[5] They reported a series of 14 patients, (average age at operation 13.3 years), who underwent thymectomy. Only two patients were under four years of age. Significant improvement occurred in 13 patients.

Myasthenia gravis in children appears in the neonatal period, or towards the middle of the first decade.[1] Onset during the second year is unusual. Furthermore, myasthenia gravis is usually not a rapidly progressive, life-threatening disease when it appears in the middle of the first decade.

We have been impressed with the lack of abnormal electromyographic findings after nerve stimulation in children with myasthenia gravis who do not have peripheral muscle weakness.

During attempts to treat our patient, it became increasingly obvious that he was going to die from aspiration disease despite large doses of anticholinesterase drugs and tracheostomy. Steroid administration was precluded by the presence of severe pneumonia. The profound weakness of oropharyngeal muscles which led to frequent aspiration was controlled after thymectomy with small doses of anticholinesterase drugs. This success contrasted with the massive doses which were ineffectual before thymectomy. The use of a gastrostomy tube facilitated maintenance of adequate nutrition, reduced the likelihood of food aspiration, and allowed safe utilization of oral anticholinesterase drugs.

Summary and Conclusion

Although the source of much speculation, the mechanism by which thymus gland function is related to myasthenia gravis is unknown. Complete remission after thymectomy is unusual. There is no way of confidently determining beforehand, which patients will benefit from thymectomy. This myasthenia patient appears to be one of the youngest subjected to thymectomy who has profited. In any event, this case reaffirms Keynes' initial observations that thymectomy may be life-saving and is beneficial to the occasional patient who has fulminating myasthenia gravis in the first several years of life.[2] In view of this experience and the report of Fonkalsrud and associates,[5] thymectomy for myasthenic children with bulbar weakness or severe limb and trunk weakness, must be seriously considered.

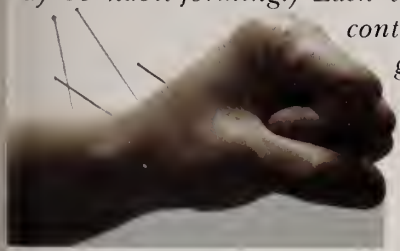
Folks who never do any more than they get paid for, never get paid for any more than they do.

Prompt relief of pain is a lot of what the practice of medicine is all about... East or West.

In much of the Far East, the analgesic efficacy of Empirin® Compound with Codeine would probably be measured against acupuncture, an ancient and traditional therapeutic system.

In America, codeine sets such a high standard for oral analgesia, that it has become a criterion in terms of which other major oral analgesics are most often measured.



Synthetic and other oral analgesics may offer some of the properties of codeine, but not one can provide both its benefits and potency. And codeine provides an antitussive bonus.

Empirin Compound with Codeine is the most widely used, and probably the most pharmaceutically elegant analgesic preparation providing codeine. It's the time-tested combination for predictable pain relief . . . whether the pain is visceral or musculoskeletal; acute or chronic.

New prescription flexibility. At your discretion, and where state law permits, a prescription for Empirin Compound with Codeine may now be refilled up to five times in six months.

Empirin Compound with Codeine No. 3 contains codeine phosphate (32.4 mg.) gr. ½. No. 4 contains codeine phosphate* (64.8 mg.) gr. 1. *(Warning—may be habit-forming.) Each tablet also contains: aspirin gr. 3½, phenacetin gr. 2½, caffeine gr. ½. Bottles of 100 and 1000.*

But for relief of Western pain

EMPIRIN® COMPOUND C CODEINE

Burroughs Wellcome Co., Research Triangle Park, North Carolina 27709

Break the ulcer circuit to hyperacidity, hypermotility and ulcer pain.

Pro-Banthine®
propantheline bromide
Relief Factor in Peptic Ulcer

orry, frustration, job pressure—all up excessive vagal currents in tients with peptic ulcer.

Pro-Banthine "insulates" the stomn, the duodenum and the lower estinal tract—the sites where ese destructive currents take their l.

This "insulation" helps block exssive enteric activity and acidity, is helping to provide the proper vironment for the healing of pep- ulcers.

It's nice to know that Pro-Banthine ovides this protection at a dosage at causes little or no discomfort d that, unlike ataractic agents, Pronthine does not cloud the patient's vareness or thought processes.

By moderating excessive vagal currents Pro-Banthine relieves spasm, acid burn and pain. By reducing gastric motility Pro-Banthine also prolongs the activity of antacids.

Indications: Pro-Banthine is effective as adjunctive therapy in the treatment of peptic ulcer. Dosage must be adjusted to the individual.

Contraindications: Glaucoma, obstructive disease of the gastrointestinal tract, obstructive uropathy, intestinal atony, toxic megacolon, hiatal hernia associated with reflex esophagitis or unstable cardiovascular adjustment in acute hemorrhage.

Warnings: Patients with severe cardiac disease should be given this medication with caution. Fever and possibly heat stroke may occur due to anhidrosis.

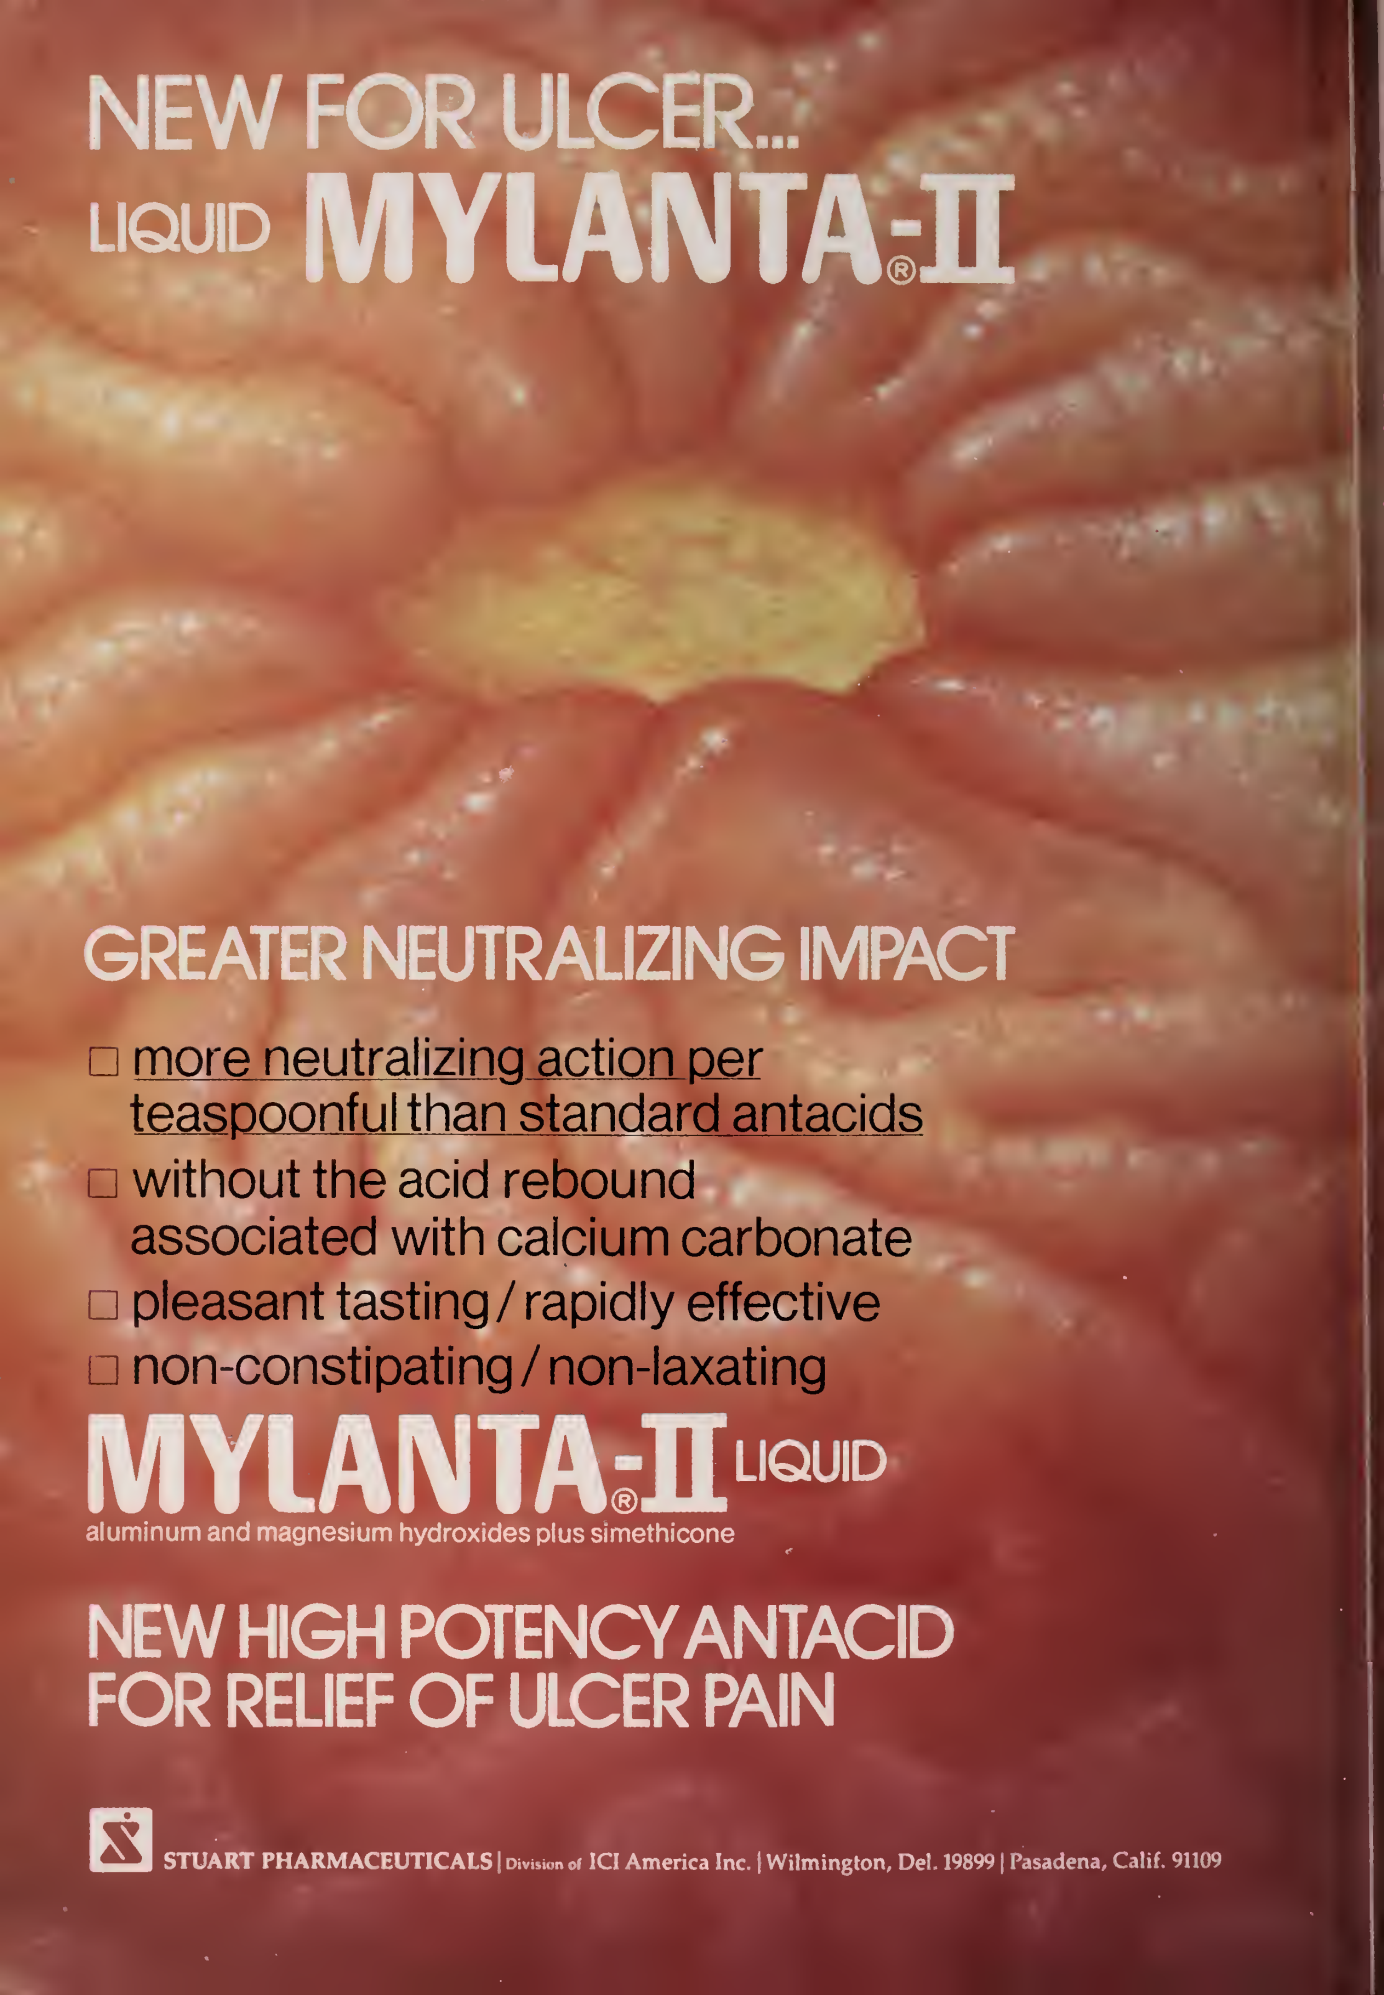
In theory a curare-like action may occur, with possible loss of voluntary muscle control. For such patients prompt and continuing artificial respiration should be applied until the drug effect has been exhausted.

Diarrhea in an ileostomy patient may indicate obstruction, and this possibility should be considered before administering Pro-Banthine.

Precautions: Since varying degrees of urinary hesitancy may be evidenced by elderly males with prostatic hypertrophy, such patients should be advised to micturate at the time of taking the medication.

Overdosage should be avoided in patients severely ill with ulcerative colitis.

Adverse Reactions: Varying degrees of drying of salivary secretions may occur as well as mydriasis and blurred vision. In addition the following adverse reactions have been reported: nervousness, drowsiness, dizziness, insomnia, headache, loss of the sense of taste, nausea, vomiting, constipation, impotence and allergic dermatitis.



Dosage and Administration: The recommended daily dosage for adult oral therapy is one 15-mg. tablet with meals and two at bedtime. Subsequent adjustment to the patient's requirements and tolerance must be made.

How Supplied: Pro-Banthine is supplied as tablets of 15 and 7.5 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg.

Cancer of the Large Bowel
Problems of Prevalence and Detection

CANCER OF THE LARGE bowel (colon and rectum) takes a formidable toll of life in most countries of western culture. Approximately 45,000 persons die annually of this cancer currently in the United States. The carcinogenic role of soot for chimney-sweep's cancer was pointed out by Percival Pott (1774). Prior thereto, it was believed to be an inherited disease. Prolonged exposure to actinic rays of the sun is recognized as a cause of skin cancer. Polycyclic hydrocarbons and phenolic oils of tobacco are believed to have carcinogenic properties that produce squamous cell cancers amongst tobacco users. The persistence of cigarette smoking, particularly, is generally the acknowledged reason for the great increase in lung cancer over the past three decades. Some investigators incline to the belief that 3.4 benzpyrene is the most active carcinogenic influence in tobacco. Excretion of the carcinogenic substances of tobacco apparently too may have a causative relationship to cancer of the urinary bladder. Aniline dye workers notably are prone to cancer of the bladder.

The genesis of most cancers, however, is obscure. One of the inexplicable and dramatic mysteries of cancer has been a 50% decline in the incidence of gastric cancer in the United States and in many western countries over the past three decades. Could better preservation of food through prevalence of refrigeration be a factor? The benzpyrene generated from frying and roasting of food has long been under suspicion as a causative factor in gastric cancer.

*See page 779.

In the dimsighted groping for a causal relationship of cancer and other diseases, an assessment of geographic distribution is a very natural first resort. Today gastric cancer has its largest mortality rate in two countries widely separated in space and culture, viz., Chile and Japan. The mortality rate of cancer of the large bowel apparently is greatest in Denmark and Scotland. Below the Sahara Desert in South Africa, cancer of the large bowel is apparently rare.

Differences in mortality rates of breast cancer are equally mystifying, relatively uncommon in Japan, the highest rates are found in Holland, England, Denmark and Scotland.[8]

Such geographic studies of cancer incidence stir the imagination, in the absence of causality information, to look for obscure factors of association identified with diet and environmental considerations. Such has been the approach of the eminent investigator of cancer amongst South Africans, Denis Burkitt,* who has boldly suggested in a number of publications (1969-71) that diet, constipation, appendicitis, diverticulitis, and cancer incidence may have similar and related associations.

Every hypothesis or premise needs to be tested. Obstruction in the proximal portion of the vermiform appendix by a fecalith is the causative factor in the genesis of appendicitis. In the presence of obstruction the appendix ruptures because of the singular great secretory capacity of the appendix in the rabbit,[9] chimpanzee[11] and man[10]—exceeding diastolic blood pressure, as studies at Minnesota demonstrated more than three decades ago.

The appendicolith is undoubtedly dietary in origin, but what element in the diet occasions its development remains an enigma. Aschoff[1] (1930) erroneously concluded that the fecalith had no causative relationship to appendicitis because the perforation occurred distal to the obstruction. His inference obviously was that the appendix, attached to the cecum, was poised in favor of absorption rather than secretion. He failed obviously to test his hypothesis.

The evolution of cancer from adenomatous polyps can be traced in the stomach, colon, and rectum. Cancer *in situ* with a long asymptomatic interval is the usual circumstance. Minnesota cancer detection studies suggest that removal of asymptomatic adenomatous polyps in the rectum decreased significantly the anticipated occurrence and incidence of rectal cancer.[2,3]

The most telling observation of 20th century cancer investigators has been that of George Papanicolaou[6] who demonstrated that recognition and destruction of *in situ* cancers of the uterine cervix has reduced the mortality from that disorder in the United States by approximately 60 percent! If all women accepted an annual "Pap smear" and submitted to treatment for a positive finding, mortality from cancer of the cervix could approach the vanishing point.

Today's surgeon of the alimentary tract has access to far more precise and reliable techniques by which to recognize gastric and colic cancers than did surgeons of my generation. Oh, to be a young surgeon again and to have the advantage of current precision techniques for detection of cancers of the gastrointestinal tract! Japanese roentgenographers[5] observed that use of air contrast media enabled them to detect quite regularly mucosal gastric defects whose existence can be confirmed by gastroscopy. Similarly, the Swedish radiographer, Welin,[13] since 1955 has continued to emphasize that adenomatous polyps 5 mm in diameter can invariably be recognized by use of air contrast studies. Unfortunately, neither in Sweden nor elsewhere, where cancer of the colon is frequent, have Welin's findings and advices had the same telling effect on cancer mortality as have the studies of Papanicolaou.

Physicians do have a moral and professional responsibility to respond to significant findings that point the way to improved achievement. Until the causative origins of adenomatous polyps in stomach, colon, and rectum are known, and reliable, preventative measures are devised to preclude their occurrence, what method other than early detection is there to assure continued betterment of the present modest accomplishment?

During the 1920-1940 years, before acceptance of proctocolectomy as the surgical treatment of ulcerative colitis, ileostomy was the standard procedure, when surgery was invoked. Despite deviation of the fecal stream, cancer frequently developed in the remaining large bowel. Similarly surgeons who perfomed colectomy and ileostomy, leaving the rectum, learned that the disease persisted in the residual rectum. There are undoubtedly a large number of patients, some of whose case histories may already have been recorded in the medical literature, who underwent colostomy because of diverticulitis. Did cancer of the rectum subsequently develop amongst any of these patients? Pursuit of such an inquiry could constitute a beginning in testing Burkitt's hypothesis.

During the last quarter of the 19th century, clues for the origin of many infectious diseases were sought in geographic studies. When Fehleisen[4] (1882) discovered and described streptococcus pyogenes, the cause of puerperal fever, erysipelas, and scarlet fever, it was obvious that the geographic incidence studies had no significance.

An annual physical examination, including digital and proctosigmoidscopic examination, as the Minnesota Cancer Detection Center study-experience demonstrates, will detect the presence of adenomatous polyps, some of which on removal are found to harbor *in situ* carcinoma. Hope for a means of nonsurgical removal of some adenomatous polyps in the colon has been quickened by arrival of the flexible colonoscope, also developed by Japanese clinicians, an instrument that already is having wide clinical trials in this country.

Long term followup studies indicate that patients who underwent subtotal excision of the large bowel for cancer, may develop a new cancer in the remaining colic segment a decade and more after the primary near-total colectomy, suggesting that residual colic mucosa, in patients who once had a colon malignancy, still harbors the threat of a new lesion. Such occurrences denote the importance of prolonged followup in all patients submitted to any operative procedure less than total colectomy; and for them an annual visual inspection of the mucosa of the remaining rectum is in order.

While we inch forward year by year in quest of echniques and methods by which the cancer nenace can be overcome, available reliable meth-)ds by which the presence of adenomatous polyps :an be detected, probably the most frequent)recursor of cancer in the large bowel, must not be neglected.

While additional testimony is sought to support the Burkitt hypothesis, that constipation is at the root of the problem of cancer of the large bowel, this observer prefers to align himself with those who ask, what is the factual evidence?

Tetanus

In the United States tetanus is a relatively minor cause of death, compared to heart disease, stroke, cancer, and many other diseases. Despite this, no unimmunized individual is totally safe from this painful and potentially fatal disease. There is no "herd immunity" to protect the person who neglects securing this health protection. Conversely, everyone runs repeated risk of injury which breaks the skin and allows tetanus spores to enter the body.

Once they enter a suitable wound, which may be as tiny as a thorn prick, the dormant tetanus spores revert to their original bacillus form and may begin to multiply. In the process, they liberate a deadly toxin which attacks the central nervous system. Often the first nerves affected are those of the head and neck which control the chewing muscles; these muscles contract rigidly, producing lockjaw.

Despite therapeutic innovations, a patient with tetanus today has about the same probability of dying as he did in 1950, over twenty years ago. That there has been a gradual decline in this period in the numbers of cases and numbers of deaths is a reflection of gradually expanding coverage of the total population with adequate active immunization. Tetanus is a disease of the unimmunized, concentrating on the extremes of age.

Tetanus toxoid is an almost ideal immunizing agent providing effective, long lasting protection. Hypersensitivity reactions may occur in persons who have received an excessive number of booster injections. Toxoid is available in both fluid and adsorbed forms. Comparative tests have shown that adsorbed toxoids are clearly superior in inducing high antitoxin titers. The promptness of antibody responses to booster doses of either fluid or adsorbed toxoid is not sufficiently different to be of clinical importance. Therefore, adsorbed toxoid is the agent of choice for both primary and booster immunization.

Primary immunization of adults consists of a series of three injections, with the second dose four to six weeks after the first, and the third dose six months to one year after the second. Four injections are usually given to children for primary immunization.

Dr. Mark Dahl* is to be commended for reminding physicians of the recent Minnesota experience with tetanus. It should reinforce the urgency of seeing that everyone in the population, including doctors and their wives, receive the protection of tetanus immunization.

Can you have a balanced diet without dairy foods?

Only if you prefer swallowing pills to eating appetizing dairy foods.

In the American diet milk and other dairy foods supply 76% of the calcium, 42% of the riboflavin, 22% of the protein and magnesium, and many other nutrients in abundant amounts.

Dairy Council's program emphasizes selecting a balanced diet from the basic 4 food groups. Individual preference provides room to pick and choose within these general guidelines.

Promoting good eating habits is just another of the many areas of interest of Dairy Council, in the pursuit of better health for everyone through sound nutrition practices.

Iodine and the Thyroid Gland

DISEASES OF THE THYROID gland occur with considerable frequency in ordinary clinical experience. These conditions occur not only as clinical entities such as myxedema or myxedema coma, but also as complications of other diseases, as exemplified by hyperthyroidism complicating heart failure.

Iodine is fundamental to the functioning of the thyroid hormone. Its curious role in this function is not yet entirely explained. However, a great deal of fundamental information is now made available to us.

The average North American diet contains 100-200 micrograms of iodine daily. It is taken up mostly by the thyroid or excreted by the kidney, and excreted in smaller amounts by the salivary and mammary glands. Iodine is converted in the thyroid gland to triiodothyronine(T3) and to thyroxine(T4), peptides linked in thyroglobulin. The thyroglobulin is stored in the thyroid gland lasting from two to four weeks. Hormones of other endocrine glands are stored in only about a four-hour supply.

Thyroglobulin does not enter the circulation normally. Proteolysis release T3 and T4 from the thyroid gland into the circulation.

Normally 10 micrograms of T4 and 50 micrograms of T3 are secreted into the circulation daily. T4 is bound to proteins which transport it. About one-half of the thyroxine is used up in seven days but one-half of the T3 is used up in a day and a half.

Some measurements of thyroid function depend on determining the quantities of T3 and T4 in the blood.

Wahner's* excellent discussion of the iodine metabolism in the thyroid function in the July issue reviews the important advances in this area. A careful reading of this paper will be helpful to physicians who diagnose and treat thyroid diseases.

Cerebral Vascular Accident

THE ARTICLE by Drs. Rockswold and Seljeskog* presents an opportunity to discuss the cerebral vascular accident (CVA). The term CVA refers to the sudden onset of neurologic symptoms in a previously well person and does not indicate a specific pathologic condition. Some have said that the term CVA might well be replaced by the word "stroke." Subarachnoid hemorrhage is one form of stroke and, as the authors point out, can have many causes. In the 45 years since Moniz first described the clinical use of cerebral angiography, marvelous progress has been made, both in the early diagnosis of brain tumors and in our understanding of the pathogenesis of stroke in all its forms.

The use of the term CVA in a diagnostic sense in medical records should be discontinued. In most cases a pathologic diagnosis can be made, and must be made if appropriate treatment is to be carried out. Since the treatment of stroke varies widely with the etiology, it is impossible to institute proper therapy without this information.

Subarachnoid hemorrhage arising from tumors or angiomas along the spinal axis is a special case in point.[1] The ready availability of information regarding the blood supply and venous drainage of these lesions has made possible surgical attack which previously was impossible. The application of microsurgery to the field of vascular lesions of the central nervous system is well under way and promises to keep pace with the progress made in angiography.

Radiology and the Health Care Problem

In this period of critical re-appraisal of goals, systems and technics of health care delivery in general, Campbell* has ably and succinctly defined and discussed the major problems as they affect radiology services. He has explored new avenues for broadening the basis for providing both radiological services and recruitment of professionals and paramedical personnel into the field and has emphasized the need for realistic self discipline in cost analysis and control as preferable to third party control.

Campbell has not only stimulated us to think and act carefully in new frames of reference, but has also, characteristically, acted in response to his convictions. Foregoing his well established position as head of radiology at Indiana University Medical Center, he has accepted the challenging and uncertain hazards of developing radiological services and education in a large urban ghetto district.

In this age of belief in commitment to and self involvement in community needs, Campbell has set us an example to emulate. Although many of us may not agree entirely with some of the innovations he suggests or the experiments he conducts, he must be admired and congratulated on the courage he demonstrates in breaking with traditional ties in his effort to find new ways of ultimately providing more people with better health care.

George D. Davis, M.D.
President of Minnesota Radiologic Society

Sino-Orbital Aspergillosis

Whereas clinicians are familiar with the often fatal outcome that follows sino-orbital infections with the genus Mucor in debilitated patients, they may not appreciate the fact that reasonably healthy individuals may become infected with the genus Aspergillum, which, though not fatal, is associated with a high incidence of visual morbidity. In his case report, Zinneman* has succinctly detailed the characteristic clinical presentation of sino-orbital mycoses. The physical findings of these somewhat uncommon infections are striking, and once seen, they are not easily forgotten. Saving the eye makes early consideration of the diagnosis of sino-orbital Aspergillosis particularly imperative. Prompt surgical intervention and fungus culture of debridement specimens will confirm the diagnosis and provide a rational basis for initiating definitive treatment.

University of Minnesota Postgraduate Medical Education

Proctology

The Division of Colon and Rectal Surgery of the Department of Surgery of the University of Minnesota Medical School in cooperation with the Minnesota Academy of Family Physicians will present a program in "Proctology" at the Nolte Center for Continuing Education on October 23-27, 1972. This program is conducted through the Office of Postgraduate Medical Education of the University of Minnesota Medical School. Fee: $160.00.

Letters to the Editor

Dear Editor:

The excellent article by Dr. Robert Rosenthal [February 1972] has what I assume is a typographical error—that is, in the sentence "The first of these was George Armstrong's Dispensary for the Poor Infants, opened in London in 1796." I am taking the liberty of sending you a photostatic copy of the front-piece of one of George Armstrong's writings which shows the date should be 1769 rather than 1796.

Hugh B. Lynn, M.D.
Rochester, Minnesota

Dear Editor

In reading the May issue of Minnesota Medicine* I noted with interest the article entitled "Laboratory Letter—Screening for Beta Hemolytic Streptococcus in the Throat" by Dr. C. W. Jarvis. There are some aspects of that article which I feel deserve comment. Dr. Jarvis advocates the use of 5-10% sheep blood in handling throat cultures for beta streptococci. The feature of beta hemolytic streptococci which physicians most often use in their office laboratories for identification is the beta hemolysis, and 10% sheep blood will fail to demonstrate hemolysis with certain group A beta hemolytic streptococcal strains. It is much more desirable, in order to use hemolysis as an accurate identification tool, to use 5% sheep blood. In addition, since streptolysin O is destroyed by oxygen, these plates should either be incubated in a CO_2 environment, or should have a small cut made in three or four appropriate locations on the plate in order to assure some subsurface growth of the streptococci with the resulting protection of the streptolysin O from surface oxygen.

Dr. Jarvis also suggests that physicians might purchase a few plates at a time from the nearest hospital bacteriology laboratory. This may not be the best advice. One can purchase sheep agar plates individually wrapped in plastic envelopes from several medium manufacturers where one is assured of a high degree of quality control, and quality control in many hospital laboratories is less than optimum with respect to the manufacture of media. Should a physician desire to buy a few plates at a time from a local manufacturer or from a local bacteriology laboratory one would hope that they would insist that the proper quality control procedures be carried out.

Dr. Jarvis indicates that human blood should not be used because this may inhibit the growth of streptococci. The reason for not using human blood is not because of the inhibition of growth of streptococci, but because human blood allows the growth of *Hemophilus hemolyticus* which may cause a confusing hemolytic reaction on blood agar plates from throat cultures. Sheep blood tends to inhibit *Hemophilus hemolyticus* and thus to minimize the aspect of confusion. In addition, it is often difficult to clearly differentiate alpha and beta hemolysis on human blood agar plates. Dr. Jarvis further indicates that beta hemolytic streptococci will not grow to within 15-20 mm of the bacitracin disc. Actually results on the kind of unstandardized situation which Dr. Jarvis advocates are very variable, and indeed many nongroup A strains will also not grow close to a bacitracin disc with a minimum inoculum. In addition, many group A strep, if a heavy inoculum is used, will grow down to within nine or 10 mm of a bacitracin disc. Bacitracin discs must also be carefully quality controlled in order to insure that potency remains. Whereas the method advocated by Dr. Jarvis has distinct advantages for the physician's office, the tenor of the article is such that the physician would be led to suspect that the above methods would give a high degree of accuracy, and such may not be the case.

John M. Matsen, M.D.
Minneapolis, Minnesota

2 ways to provide a daily therapeutic supply of Vitamin C: 15 baked potatoes (skins and all!) or one capsule of Allbee® with C

About 20 mg. Vitamin C in one baked potato (2½" diameter).

To many people the evening meal just isn't complete without potatoes. But your patient would have to eat 15 of them (skins and all!) to get as much Vitamin C as is contained in just one Allbee with C capsule taken daily. A bottle of 30 (month's therapeutic dose) supplies as much ascorbic acid as 450 potatoes, plus full therapeutic amounts of the B-complex vitamins. For the patient who is counting calories, Allbee with C is small potatoes because the B's and C are water soluble. Consider the number of calories in 15 potatoes, not to mention the mountain of butter and sour cream. Albee with C is available at pharmacies in the handy bottle of 30 and the economy size of 100 on your prescription or recommendation.

A. H. Robins Company, Richmond, Va. 23220

Fifty Club

Owen H. Wangensteen, M.D.

From Amateur Accoucheur to Pigs to Professor of Surgery

THIS FIFTY YEAR CLUB member graduated with a Bachelor's Degree in Medicine in December 1921. At Minnesota, completion of an Internship then was mandatory for satisfaction of the M.D. degree. The writer came into medicine through the back door, through the portals of pigs and manure, a goodly spread of each. As a junior in high school my father had 50 sows that could not farrow their young. The veterinarian advised sending the sows to South St. Paul. During three weeks away from school all the sows, save two, were salvaged and approximately 300 piglets. I learned from the effort that a young boy's hand was superior to any instrument devised for the purpose. Thereafter my father insisted that I consider seriously becoming a doctor. However, my ambition was to be a farmer and a good one.

After three years in the College of Science, Literature, and Arts at the University of Minnesota and much manure hauling, loaded by hand in the hot summer of 1917, this Club member decided to capitulate to his father's wishes and to have a go at medicine. Much to my astonishment, I found the study far more agreeable than I had ever dreamed it could be. I came quickly to know that our language stands in great need of a word to connote transition from rejection to acceptance, a circumstance that touches all of us many times in a long life.

I had firmly decided to become an internist, but as a junior medical student (1920) on hearing the first lecture in Surgery from its Chairman, Dr. Arthur C. Strachauer, I decided before the lecture was over that surgery would be my career. That lecture persuaded me that the results of the ministrations in this discipline were more readily identifiable and more dramatic than those of the physician.

My stimulus to seek a career in academic surgery stemmed from my association with Dr. George E. Fahr, whose presence at the University in 1921 was like a gust of fresh, cool, and refreshing air into a smoke filled room. After completion of an internship at the University Hospital and a Surgical Fellowship during which I was privileged to have an exchange year at the Mayo Clinic, I became successively Instructor and Assistant Professor of Surgery. In the summer of 1927 at the urging of Dean Lyon and Dr. George E. Fahr, I took off for a study trip abroad which time was spent in Bern, Switzerland and visiting German, Viennese, Italian, English and Scottish surgical clinics. It was a unique experience. On my return in the Fall of 1928, I was made an Associate Professor and became the Department's Chairman in January 1930, after Dean Lyon and his search committee had sought in vain for an acceptable candidate. Two had been interviewed, Dr. Francis Newton from Harvard and the other Dr. Mont Reid from the University of Cincinnati, a trainee of Halsted's at The Hopkins. Both said to me in substance, "There is nothing here nor will there ever be."

Three years after assuming the Chairmanship, I ran afoul of our legendary and inspiring teacher in anatomy, Dr. Richard Scammon, then Dean of the Medical Sciences. However, J. Charnley McKinley, Acting Chairman of the Department of Medicine, who represented me in the discussions with Dean Scammon, Dean E. P. Lyon to whom I owed my appointment, Dr. Lotus D. Coffman, President of the University, and William J. Mayo, Regent, felt otherwise and my appointment continued uninterrupted.

Over the years a few opportunities came my way to go to other academic institutions with facilities and prestige the equal of or better than those which I enjoyed

at Minnesota. However, I felt that the University of Minnesota had treated me with kindly forebearance and I felt obligated to try to build a strong department worthy of the citizens of Minnesota. Moreover, the reprieve and the rare gift of a second chance were still in the foreground of my mind. Additionally, I was quite aware and conscious of the circumstance that an environmental atmosphere, unlike baggage, is not portable.

With the cooperative help of Dr. M. B. Visscher, Professor of Physiology, a large number of talented Surgical Fellows, skilled in operative surgery, gained training in the physiology of the circulation, an arrangement and situation that made it possible for a brilliant group of young surgeons to contribute greatly to the establishment of intracardiac surgery, one of the most significant contributions to medicine during my academic tenure.

Retirement came in June 1967, after 52 years of association with the University as man and boy. Dame Fortune had smiled kindly on my efforts; comfortable colleagues and good friends, who appreciated me far beyond my expectations and worth, made for me a very pleasant and rewarding career at Minnesota. Now after five years of retirement I find myself launched on a second career as an amateur historian of surgery attempting to trace the development of surgery, from the chaotic confusion of the pre-Listerian era, to its emergence as a scientific discipline.

My own work has been essentially that of general plumber of the alimentary canal. It has been my great privilege to be the regimental water carrier and the sideline cheerleader for one of the finest circles of talented and innovative surgeons gathered under one institutional roof in the 20th century. As the spokesman for this great orchestral band, I can only say, we are beholden to wonderful professional and interdisciplinary colleagues, to an approving and generous administration, and to the bountiful people of Minnesota, who have built here a truly great University, within whose walls and halls, the impossible can be achieved.

Request for Physican's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers has received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Because of limitation of space, pictures oriented horizontally are preferred. All pictures will be returned if identified with the name and address of the physician. Please submit your pictures as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

Viewing Box

Cystic Lung Lesion

C. R. McWILLIAMS, M.D. AND JAMES R. SCHUFT, M.D.

CHEST FILMS (Figures 1 and 2) are those of a 42-year-old Caucasian female.

The patient stated that she consulted a physician 14 months ago because of swelling involving her left foot. A physical examination at that time, including a chest Xray, revealed a spot on her lung. There was some question of tuberculosis and she was started on antituberculous medication. The symptoms regarding her foot subsided. Three months after the initial examination a chest Xray was repeated, revealing a slight increase in size of the spot on her right lung. The area in question had developed a cystic appearance.

Three months prior to her admission to the hospital, the patient stated that she developed the "flu" and has not felt well since then. She had a productive cough, had had intermittent hemoptysis and night sweats for the past two months and had had an eight pound weight loss.

The patient lived in the Los Angeles area for a number of years and made frequent trips to the San Joaquin Valley region. Physical examination revealed clubbing of all fingers and toes and mild swelling of both ankles. The physical examination was otherwise normal. The chest Xrays were obtained at this time. A needle biopsy of the lateral aspect of the right lung cyst was performed and

Radiologists, Magic Valley Memorial Hospital, Twin Falls, Idaho.

Figure 1

Figure 2

approximately 10 cc. of thick fluid was aspirated from the cavity. The material was examined by smear and culture. Hemophilus influenza was cultured from the aspirated material. Cultures for fungi revealed no growth during a four-week period. Cytological studies revealed no evidence of tumor cells.

Differential diagnosis: 1. Tuberculosis.
2. Non-tuberculous lung abscess.
3. Coccidioidomycosis.
4. Echinococcus cyst.
5. Neoplasm.

A thoracotomy was performed and the cystic structure, which was present within the superior aspect of the right lower lobe, was opened. Frozen section studies were made of the wall of the cystic structure revealing a poorly differentiated squamous cell carcinoma.

A right pneumonectomy was performed. There was no evidence of regional lymph node involvement. A nodular area in the apical region of the right upper lobe 1.5 cm. in diameter was sectioned and revealed the presence of a bronchiolar carcinoma. It was well differentiated and quite different histologically from the cavitary mass in the lower lobe.

The patient's chest films were reviewed and this right apical lesion could not be visualized, even when the "retrospectoscope" was used.

Final Diagnosis: Poorly differentiated squamous cell carcinoma.
Bronchiolar carcinoma.

I spent my shining hours washing faces, serving rations, giving medicine, and sitting in a very hard chair, with pneumonia on one side, diphtheria on the other, two typhoids opposite, and a dozen dilapidated patriots, hopping, lying and lounging about, all staring at the new "nuss," who suffered untold agonies, but concealed them under as matronly an aspect as a spinster could assume, and blundered through her trying labors with a Spartan firmness, which I hope they appreciated, but am afraid they didn't. Having a taste for "ghastliness," I had rather longed for the wounded to arrive, for rheumatism wasn't heroic, neither was liver complaint, or measles; even fever had lost its charms since "bathing burning brows" had been used up in romances, real and ideal. But when I peeped into the dusty street lined with what I at first had innocently called market carts, now unloading their sad freight at our door, I recalled sundry reminiscences I had heard from nurses of longer standing, my ardor experienced a sudden chill, and I indulged in a most unpatriotic wish that I was safe at home again, with a quiet day before me.*

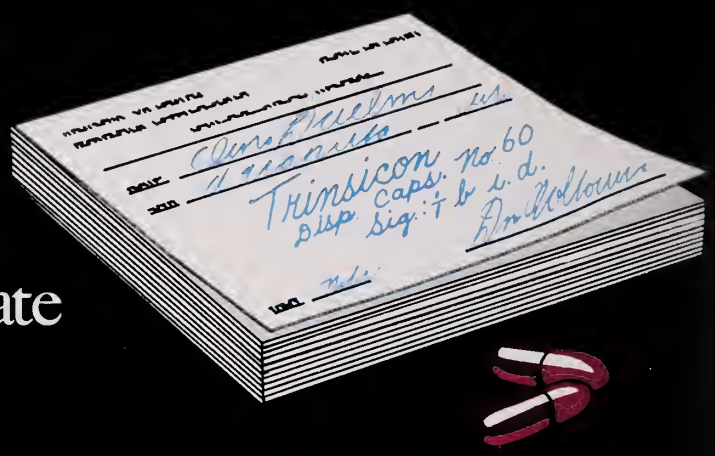
Iron therapy for anemia is almost as old as history itself

Celsus's empirical use of iron

Aulus Cornelius Celsus recommended an unusual form of iron therapy for the treatment of enlarged spleens—the oral administration of water that blacksmiths had used for dousing white-hot iron.



For more modern anemia therapy

Trinsicon®

Hematinic Concentrate with Intrinsic Factor

(See reverse side for prescribing information.)

Trinsicon®
Hematinic Concentrate with Intrinsic Factor

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	240 mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin	7.5 mcg.
(The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	
Iron, Elemental (as Ferrous Fumarate)	110 mg.
Ascorbic Acid (Vitamin C)	75 mg.
Folic Acid	0.5 mg.

Indications: Trinsicon is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia. Therapeutic quantities of hematopoietic factors that are known to be important are present in the recommended daily dose.

Vitamin B_{12} with Intrinsic Factor—When secretion of intrinsic factor in gastric juice is inadequate or absent (e.g., in Addisonian pernicious anemia or after gastrectomy), vitamin B_{12} in physiological doses is absorbed poorly, if at all. The resulting deficiency of vitamin B_{12} leads to the clinical manifestations of pernicious anemia. Similar megaloblastic anemias may develop in fish tapeworm (*Diphyllobothrium latum*) infection or after a surgically created small-bowel blind loop; in these situations, treatment requires freeing the host of the parasites or bacteria which appear to compete for the available vitamin B_{12}. Strict vegetarianism and malabsorption syndromes may also lead to vitamin B_{12} deficiency. In the latter case, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient.

Potency of intrinsic factor concentrates is determined physiologically, i.e., by their use in patients with pernicious anemia. The liver-stomach concentrate with intrinsic factor and the vitamin B_{12} contained in two Pulvules Trinsicon provide 1½ times the minimum amount of therapeutic agent which, when given daily in an uncomplicated case of pernicious anemia, will produce a satisfactory reticulocyte response and relief of anemia and symptoms.

Concentrates of intrinsic factor derived from hog gastric, pyloric, and duodenal mucosa have been used successfully in patients who lack intrinsic factor. For example, Fouts *et al.* maintained patients with pernicious anemia in clinical remission with oral therapy (liver extracts or intrinsic factor concentrate with vitamin B_{12}) for as long as twenty-nine years.

After total gastrectomy, Ficarra found multifactor preparations taken orally to be "just as effective in maintaining blood levels as any medication that has to be administered parenterally." His study was based on twenty-four patients who had survived for five years after total gastrectomy for cancer and who had been taking two Pulvules Trinsicon daily.

Folic Acid—Folic acid deficiency is the immediate cause of most, if not all, cases of nutritional megaloblastic anemia and of the megaloblastic anemias of pregnancy and infancy; usually, it is also at least partially responsible for the megaloblastic anemias of malabsorption syndromes, e.g., tropical and nontropical sprue.

It is apparent that in vitamin B_{12} deficiency (e.g., pernicious anemia), lack of this vitamin results in impaired utilization of folic acid. There are other evidences of the close folic acid-vitamin B_{12} interrelationship: (1) B_{12} influences the storage, absorption, and utilization of folic acid, and (2), as a deficiency of B_{12} progresses, the requirement for folic acid increases. However, folic acid does not change the requirement for vitamin B_{12}.

Iron—A very common anemia is that due to iron deficiency. In most cases, the response to iron salts is prompt, safe, and predictable. Within limits, the response is quicker and more certain to large doses of iron than to small doses.

Each Pulvule Trinsicon furnishes 110 mg. of elemental iron (as ferrous fumarate) to provide a maximum response.

Ascorbic Acid—Vitamin C plays a role in anemia therapy. It augments the conversion of folic acid to its active form, folinic acid. In addition, ascorbic acid promotes the reduction of ferric iron in food to the more readily absorbed ferrous form. Severe and prolonged vitamin C deficiency is associated with an anemia which is usually hypochromic but occasionally megaloblastic in type.

Contraindications and Precautions: Anemia is a manifestation that requires appropriate investigation to determine its cause or causes.

Folic acid *alone* is unwarranted in the treatment of pure vitamin-B_{12}-deficiency states, such as pernicious anemia. Indeed, the use of folic acid in large doses in pernicious anemia without adequate vitamin B_{12} may result in hematologic remission but neurological progression.

As with all preparations containing intrinsic factor, resistance may develop in some cases of pernicious anemia to the potentiation of absorption of physiological doses of vitamin B_{12}. If resistance occurs, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient. No single regimen fits all cases, and the status of the patient observed in follow-up is the final criterion for adequacy of therapy. Periodic clinical and laboratory studies are considered essential and are recommended.

In extremely rare instances, skin rash suggesting allergy has been noted following the oral administration of liver-stomach material. Allergic sensitization has been reported following both oral and parenteral administration of folic acid.

Hemochromatosis and hemosiderosis are contraindications to iron therapy.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastrointestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects in the iron-sensitive patient.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500 and in Identi-Dose® (unit dose medication, Lilly) in boxes of 100.

Lithium

BURTON P. GRIMES, M.D.

LITHIUM WAS IDENTIFIED as an element in 1818. is a light element with an atomic number of iree: an alkali metal of the sodium and potas- um group. In the 1940s it was used as a taste ubstitute for individuals who were on a salt-free iet. Unfortunately, the drug's toxicity included an ncephalitic syndrome which led to a number of atalities.[1,2] These fatalities attributed to lithium hloride) led to its withdrawal from the market.

Also in the late 1940s Cade in Australia noted thargy in guinea pigs following ingestion of lith- um. His clinical study of 10 manic patients was he first to suggest a psychotropic effect for lith- um.[3] A controlled study published by Schou in 954 demonstrated effectiveness of lithium in cute manic states.[4] Subsequently, the literature ontains detailed references to lithium metabolism, oxicity, use in prophylaxis and results in treatment f both mania and depression.

Methods

In order to use lithium in this country, one must irst have an investigation permit, then a source f the drug, and finally a means of measuring erum lithium levels. The dose of lithium carbo- nate is usually 0.3 gm to 0.6 gm. three times a lay. Blood tests are made at least twice weekly luring the initial control period. A level of less han 1.5 meq/liter is rarely associated with toxic manifestations.

From June 1967 until August 1970, we started a total of 54 patients on lithium (Table 1). The age range was 18 to 79; the average was 50.

Results

Two patients died. On autopsy we were unable to connect the deaths with lithium. One of the patients who died had pneumonia, and the other a myocardial disease. Four patients were discon- tinued respectively for polyuria, diarrhea, distance from the hospital, and transfer elsewhere for sur- gery. Three patients quit. Nine have been trans- ferred to other institutions or to care outside the hospital while continuing lithium therapy.

Address reprint requests to: Burton P. Grimes, M.D., St. Peter State Hospital, St. Peter, Minnesota, 56082.

Complications

Gastrointestinal

One 64-year-old man developed a severe case of diarrhea the first day he received a full dose of lithium. The diarrhea stopped several days after discontinuing the lithium. Transitory and rarely severe gastrointestinal symptoms are common dur- ing the first weeks.

Urinary

A woman on lithium treatment for depression discontinued lithium because of the development of urinary frequency.

TABLE 1
Summary of Lithium Carbonate Patients at St. Peter State Hospital

	N	%
Total patients started on Lithium	54	100 %
Total patients currently in the study and in the hospital[1]	23	42.6
Total patients lost in the hospital from the study and	2	3.7
Total patients lost from the study		
Discharged improved—to be continued on lithium[2]	16	29.6
Transferred improved to other hospitals	5	9.3
Discharged improved—d.v.* urinary frequency	1	1.8
Discharged improved—d.v. because of distance	1	1.8
Discharged from hospital—questionable improvement	2	3.7
Discontinued because of side effects	1	1.8
Discontinued for surgery	1+	1.8
Deaths	2	3.7
	54	100.0

[1]Includes one patient who was discharged to nursing home and returned.
[2]Includes one patient who was discharged, returned, and dis- charged.
+Had improved.
*dv—discontinued of own volition.

Neuromuscular

The patients in this study did not show significant neuromuscular abnormality during treatment with lithium. However, this is an important area of toxicity. Patients with a high blood level of lithium develop a gross muscular tremor, most obvious in its interference with writing. Tremor is an indication for immediate reduction of dose. Ataxia is also an early manifestation of a toxicity and likewise is an indication for lowering the dosage.

Thyroid

Three of the patients in this study showed an increase in T_4 levels which remained within normal limits. One patient became hypothyroid. These abnormalities with thyroid function have not been reported previously. A cause and effect relation is not definitely established in the patients we studied. Goiter has been reported to have developed in 12 of 330 patients,[6] but was not seen in our study.

Comment

The major benefit of lithium therapy is in the control of hyperactivity. This was apparent in 85 percent of patients we treated. It may be necessary to add other types of medication or perhaps electric shock to control acute hyperactivity until the lithium becomes effective. The majority of pa tients came under control within 10 days o starting lithium (Table 2).

TABLE 2

Percentages of 54 St. Peter State Hospital Patients Showing Improvement on Individual Target Symptom Rating Scales at Various Time Intervals During the First 30 Days of Treatment on Lithium Carbonate

Improvement Shown In:*	N	%
1-10 days	28	51.8
11-14 days	7	13.0
15-21 days	3	5.6
22-30 days	8	14.8
Variable, Questionable or No Improvement	8	14.8

* Improvement is taken as the point at which an individual's score on his individual Target Symptom Scale drops below the pretreatment level and either remains constant or continues to decrease for the remainder of the 30-day period.

Received 1970.

Another benefit is the lack of side-effects o maintenance. Manic patients have commented o the freedom from a feeling of fogginess whic they had experienced with the large doses o phenothiazines they had required on previous epi sodes. There is also a longer interval betwee attacks. While manic attacks are ordinarily recur rent, the patient can expect several more symp tom-free months between attacks while on lithiun than with any other mode of therapy. For exam ple, the control of hostility while taking lithiun has made it possible for one patient to be out o the hospital successfully for two years. She ha re-established relationships with her family and i living and working out of the hospital.

The control of hostility is particularly importan in the nursing care and supervision of the patient With lithium therapy, the improved social adjust ment in the hospital makes life much mor pleasant, not only for the patient, but for all th hospital personnel.

The cost of treatment is measured in terms o periodic supervision while on maintenance ther apy in the community. Laboratory costs will in clude monthly or more frequent serum lithium levels; the cost for equipment to determine serum lithium should be less than $1,000. The thyroid activity should probably be measured at two-month intervals. Lithium salts are all inexpensive and should not be a financial burden if they are released for general use.

For further details on the use of lithium carbonate for manic depressive states consult references six to eight.

Summary

Fifty-four patients were started on lithium for the control of manic and/or depressive reactions. Definite improvement was seen in 85.2% of the patients.

Fracture Conference

Ankle Fractures

JOE L. NETTLES, M.D., JOHN A. ELSTROM, M.D. and
EINER W. JOHNSON, JR., M.D.

Dr. Joe L. Nettles:

Percival Pott of London in 1769 has been credited with the first attempt at the description of the mechanism of fracture-dislocation at the ankle, with its associated ligamentous injuries. Dupuytren, in 1816, and Cooper, in 1822, pointed out the significance of talar motion and its relation to the malleoli as the force that initiates ankle injuries. Maisonneuve, in 1840, however, was the first to appreciate that external rotation of the foot around the vertical axis of the talus is a major etiologic factor in these injuries. Expansion and modification of this work, by Ashhurst and Bromer[1] in 1922, Lauge-Hansen[2,3] in 1948 and 1952, and Burwell and Charnley[4] in 1965, have further defined the individual components of ankle injury.

Two cases of ankle fractures will be presented with the purpose of discussing their nature and its relationship to treatment.

Case 1

Dr. John A. Elstrom:

A 44-year-old salesman was injured when a cow fell on his left leg. Examination in the emergency room at admission showed an obvious deformity of the ankle. Circulation and sensation were intact.

Dr. Charles F. Mess:

The Xray revealed a vertical fracture of the medial malleolus from the level of the ankle mortise (Figure 1 *A* and *B*). The lateral malleolus was also fractured at the level of the ankle joint. This appeared to be an unstable fracture.

Dr. Nettles:

The fracture, tested under anesthesia, was grossly unstable. It was so unstable that it would not respond to closed methods, especially the vertical fracture of the medial malleolus.

Dr. Mess:

For reduction, two screws probably should have been used to counteract any rotational forces, as the medial fragment looked large enough to adequately accept a screw.

Dr. Nettles:

We used one screw and a Kirschner wire at operation, because we thought that the medial malleolar fragment was too small to tolerate a second screw. We also used a Rush pin at the lateral malleolar fragment (Figure 1 *C* and *D*). The patient subsequently has done well. We removed the Kirschner wire at three weeks because it was causing some irritation. At the end of two months, healing had obliterated the medial fracture line.

Case 2

Dr. Elstrom:

A 49-year-old construction worker was struck by a piece of steel and sustained an open injury to his left ankle. He was brought to the emergency room approximately 30 minutes after the accident (Figure 2 *A* and *B*).

Dr. James J. Haven:

This patient had a severe fracture dislocation of the ankle; the medial malleolus was fractured horizontally at the mortise. The fibula was fractured fairly high up, and there was diastasis between the tibia and fibula.

Dr. Nettles:

Dr. Buckley, do you differentiate the types of diastasis seen in ankle fractures?

Dr. John P. Buckley:

Yes, there are two varieties. *Classic diastasis* is considered a separation of the fibular shaft from the tibia; whereas *interosseous diastasis* between the two fibular fracture fragments at the level of the joint is probably just as significant clinically and may allow lateral displacement of the talus.

Dr. Nettles:

The fracture was a compound one. The articular surface of the tibia was exposed (Figure 3 *A*) and the medial malleolus was sheared off. The patient was taken to the operating room for a thorough debridement of the wound. The medial malleolar fragment was restored to its tibial "seat," and the dislocation was reduced very satisfactorily (Figure 3 *B* and *C*). The torn posterior tibial tendon was repaired. We elected not to fix the lateral fracture because of the severity of the open injury and the risk of infection if further incisions were made. The wound was closed over a Penrose drain (Figure 3 *D*). The patient did well.

Dr. Einer W. Johnson, Jr.:

His wounds healed nicely. However, he had several superficial abrasions across the anterolateral aspect of his leg, and these took a while to heal. We were worried about the external malleolus. I thought that once the

Doctors Nettles and Elstrom are Residents in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota) Rochester.

Dr. Johnson is a Consultant, Department of Orthopedics, Mayo Clinic and Mayo Foundation.

Fracture Conference held July 7, 1969.

medial malleolus was fixed the external malleolus would fall into line, but that did not happen. Ultimately, three and one-half weeks after the initial treatment, a Rush nail was placed up the external malleolus, which gave an adequate reduction of the mortise (Figure 4 *A* and *B*).

Dr. Mark B. Coventry:

The fibula was not posterior, was it? This can happen. The lateral malleolus will be displaced posteriorly, and this positioning may escape recognition.

Dr. Johnson:

No, the lateral malleolus seemed to be locked, ju the way it looks in Figure 3 B, with the distal fragmer pushed medially and held by the proximal fragment. Fr quently, lengthening the malleolus enough to get it r duced after three weeks is difficult.

Discussion

Dr. Richard S. Bryan:

Interestingly, in these two cases, the mechan

Fig. 1 (Case 1)—Bimalleolar fracture of left ankle. (A) and (B) before reduction. Anteroposterior (A) and lateral (B) views. (C) and (D) After open reduction and internal fixation.

ism of injury was the opposite. In the first case, it was supinated, and in the second, the foot was pronated.

Dr. Nettles:

Ashhurst and Bromer,[1] while pointing out the significance of the work of Maisonneuve, first attempted to classify fractures in relation to their causative mechanism. Subsequently, Lauge-Hansen,[2,3] and Burwell and Charnley[4] have further refined this classification (Figure 5). They divided the injuries into five categories.

Supination-lateral rotation fractures are produced by lateral rotation of the supinated foot. The talus rotates against the lateral malleolus first, rupturing the anterior tibiofibular ligament. Subsequently, a spiral or oblique fracture of the lateral malleolus occurs at the level of the ankle mortise. Further lateral rotation either ruptures the posterior tibiofibular ligament or fractures the posterior malleolus. The originally relaxed medial deltoid ligament finally comes into stress, resulting in a tear of the ligament or, more commonly, in a fracture of the medial malleolus.

Pronation-lateral rotation injury is the most common. In this situation the foot is in an attitude of pronation. The deltoid ligament, which is under tension, either ruptures or pulls away the medial malleolus in the first stage. Then the anterior tibiofibular ligament and the interosseous ligament are disrupted at the second stage, followed by a fracture of the fibula, typically three inches or more above the ankle joint. Ultimately, further rotation can produce a posterior fracture at the posterior tibial margin.

A supination fracture, or the supination-adduction fracture of Lauge-Hansen, can be considered an inversion fracture. This begins with a traction fracture of the lateral malleolus at or below the level of the ankle joint. Then the talus exerts enough pressure on the medial malleolus to fracture it, usually almost vertically, as the talus shifts into adduction. Vertical disruption of the medial malleolus is characteristic of the supination fracture.

The pronation or abduction fracture is also referred to as an eversion fracture. There the first stage is either a rupture of the deltoid ligament or a break of the medial malleolus. Then pressure of the talus against the fibular produces a typical fracture through the fibula, slightly above the ankle joint. There is usually a small comminuted fragment on the lateral portion of the fibular fragment by which this type of injury can be identified. In fact, according to Burwell and Charnley,[4] this is the advantage of the classification: one can understand the mechanism of injury by looking at the level of the fibular fracture or at the type of fibular fragment.

A fifth category, very uncommon, is a *comminuted distal tibial and fibular fracture* due to a fall from a height.

Lauge-Hansen[2,3] developed this classification to help him in his closed treatment of ankle injuries with very good success. However, Burwell and Charnley[4] have taken the same etiologic classification and used it in their advocacy of the open-type or surgical treatment. Recently they[4] reviewed a series of 137 fractures, about 98% of them falling into these categories, with most of the patients being treated by open reduction with internal fixation. Eighty-two percent had good results; 14%, fair results, and 4%, poor results. There were six instances of infection, five of them minor.

Burwell and Charnley also pointed out the *disadvantages of closed treatment* of these fractures: (1) the difficulty in achieving and maintaining accurate reduction, (2) the duration of immobilization, and (3) the frequency of malunion or nonunion. After internal fixation, they do not apply plaster. They leave the wound exposed and encourage active exercise of the joint. After two or three weeks, when active motion of the joint has been obtained, the patient is placed in a walking cast for about five weeks.

Dr. Coventry:

I think that you must know the mechanism of injury and the forces pertaining before you can accurately reduce the fracture and hold it. The key is probably the medial malleolus. We have overemphasized this because there are some patients in whom the medial malleolus has been reduced but in whom the ankle mortise is still widened. We have to look at the interosseous membrane because, if that remains spread, the result will be poor. Any diastasis has to be reduced.

Dr. Nettles:

Would you fix the interosseous membrane? Would you put any kind of fixation across the two bones?

Dr. Coventry:

Yes indeed, if it is separated and cannot be

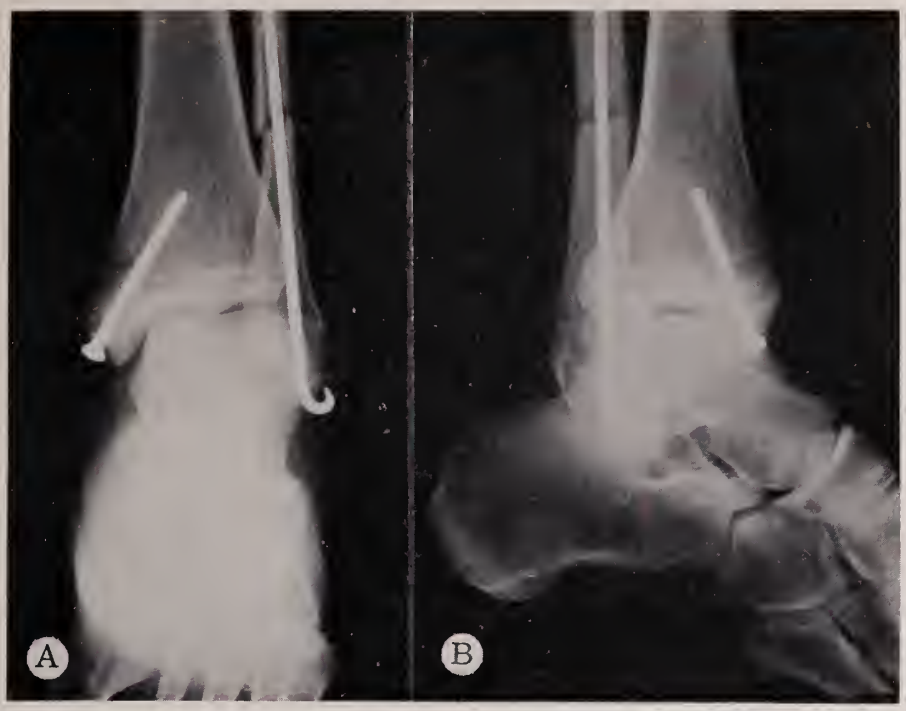

Fig. 4 (Case 2)—(A) and (B) After internal fixation of distal fibula with Rush pin for correction of distal tibiofibular diastasis.

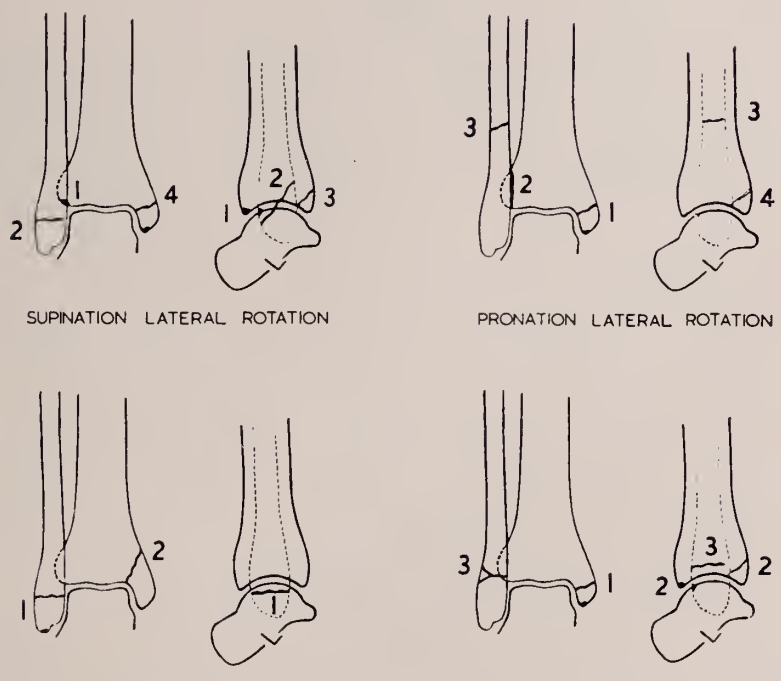

Fig. 5—Four common types of fracture in Lauge-Hansen classification. (From Burwell, H. N., and Charnley, A. D.: The Treatment of Displaced Fractures at the Ankle by Rigid Internal Fixation and Early Joint Movement. J Bone Joint Surg [Brit] 47:634, 1965. By permisison.)

reduced any other way.

Dr. Nettles:

Burwell and Charnley[4] have stated that they rarely put a pin across the two bones.

Dr. Coventry:

What do they do if they have a separation?

Dr. Nettles:

They maintain that if the injury to the malleolus is reduced and stabilized, the diastasis is also reduced and will be maintained in proper position. They further point out that in their series, although classic diastasis occurred in 24 patients, it was not always visible on Xray.

Dr. Bryan:

One point should be made: if you put a screw from the fibula into the tibia, you should be very cautious about having the patient walk, whether he is in or out of a cast, because the screw will break. The screw must be removed, usually at about six weeks.

Dr. Joseph M. Janes:

I think the vertical compression fractures at the lower end of the tibia are difficult to treat by open reduction. Often they can be treated by putting a pin through the os calcis, placing the extremity on a "Bohler frame" for traction for several weeks until the fracture is secure then putting the extremity in a cast. But opening up the lower end of the tibia to provide internal fixation is an almost impossible situation, because of the great degree of comminution.

Dr. Nettles:

In conclusion, these two cases demonstrate the importance of discovering all the injuries in an ankle fracture. From an informed evaluation of the roentgenogram, the individual components of an ankle injury in their correct time sequence can be determined and the presence of intermediate ligament injuries inferred. The evaluation can be further supplemented by examination under anesthesia with stress films and by arthrography.

As Ashhurst and Bromer[1] have stated: "It is perhaps unnecessary to argue the desirability of classification; for, without classification, the relation of one lesion to another can be neither remembered nor understood in any department of knowledge; and comprehension is a prerequisite for intelligent memory and for rational diagnosis and treatment." Finally, Burwell and Charnley[4] have pointed out that accuracy of reduction is probably the major factor in the prevention of subsequent arthritis of the ankle.

"Shock Lung," plus related subjects

Dr. James Wilson, Duke University, Durham, North Carolina.

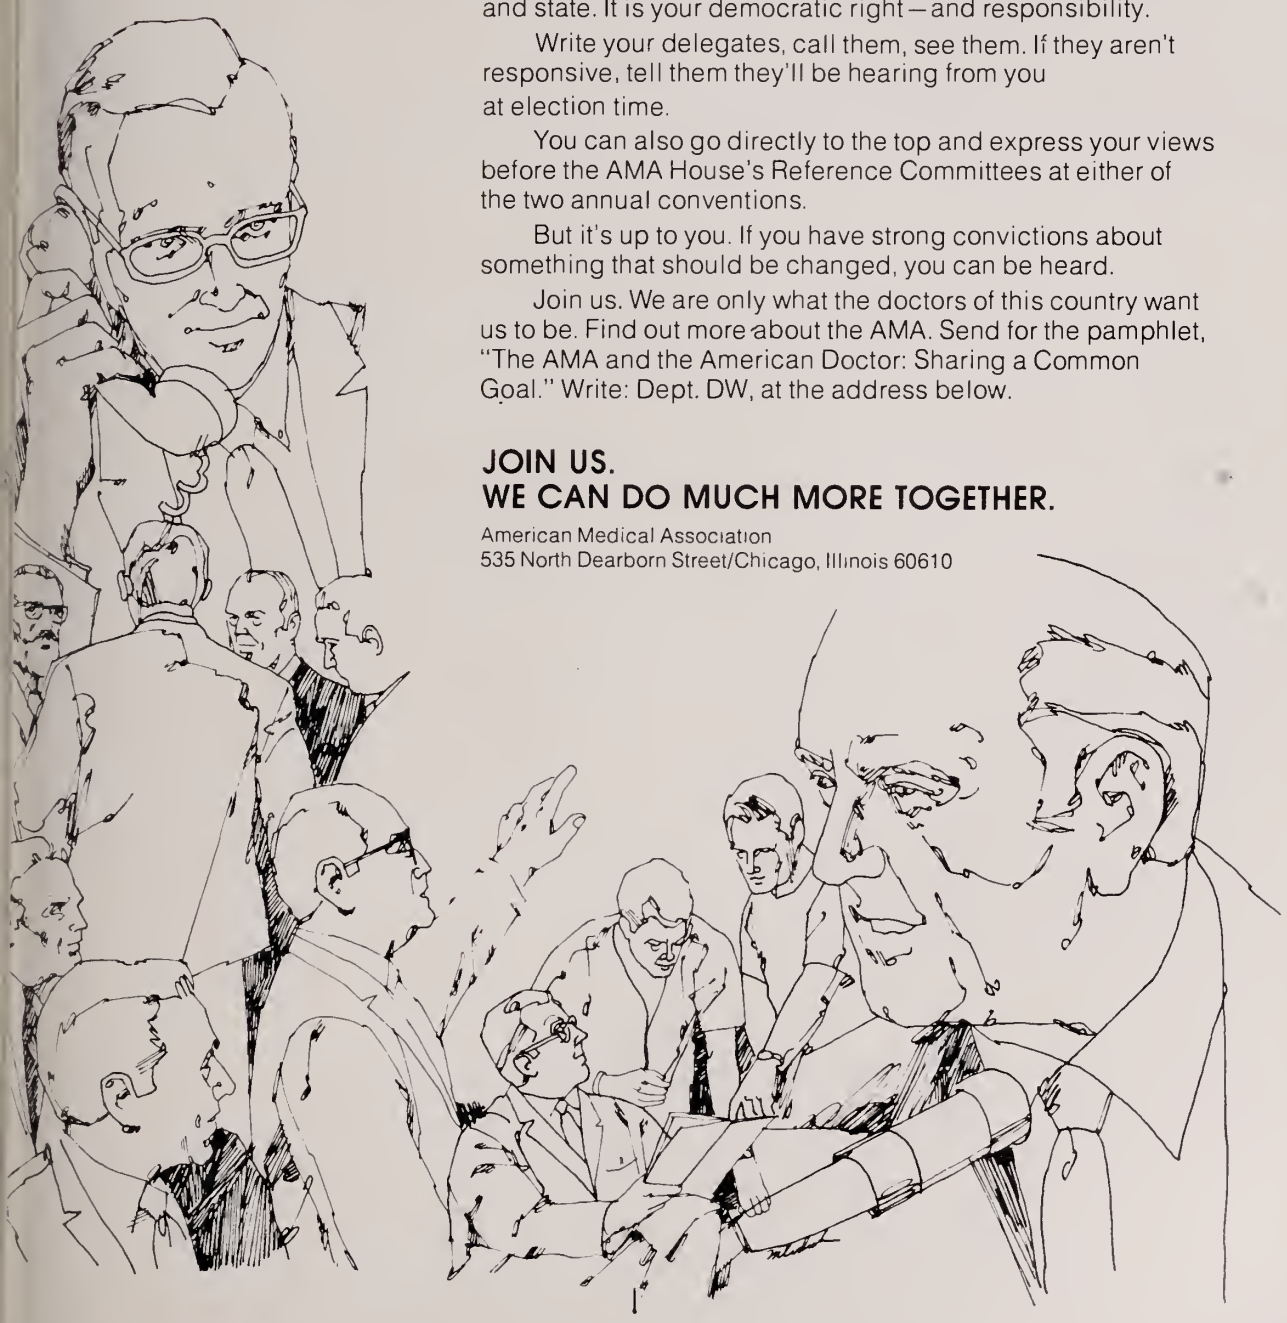
Change the AMA!

Maybe you're one of those doctors at odds with some AMA policies. Your question is: how do you change them?

First, consider who sets those policies. In a real sense, it is you. You elect the delegates to your state association. They in turn elect the delegates who will represent your views in the AMA House.

As an active, involved member, you can influence policy by making your views known to your delegates, both national and state. It is your democratic right—and responsibility.

Write your delegates, call them, see them. If they aren't responsive, tell them they'll be hearing from you at election time.



You can also go directly to the top and express your views before the AMA House's Reference Committees at either of the two annual conventions.

But it's up to you. If you have strong convictions about something that should be changed, you can be heard.

Join us. We are only what the doctors of this country want us to be. Find out more about the AMA. Send for the pamphlet, "The AMA and the American Doctor: Sharing a Common Goal." Write: Dept. DW, at the address below.

JOIN US.
WE CAN DO MUCH MORE TOGETHER.

American Medical Association
535 North Dearborn Street/Chicago, Illinois 60610

When you select this familiar antibiotic for IV infusion you have available a broad dosage range that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

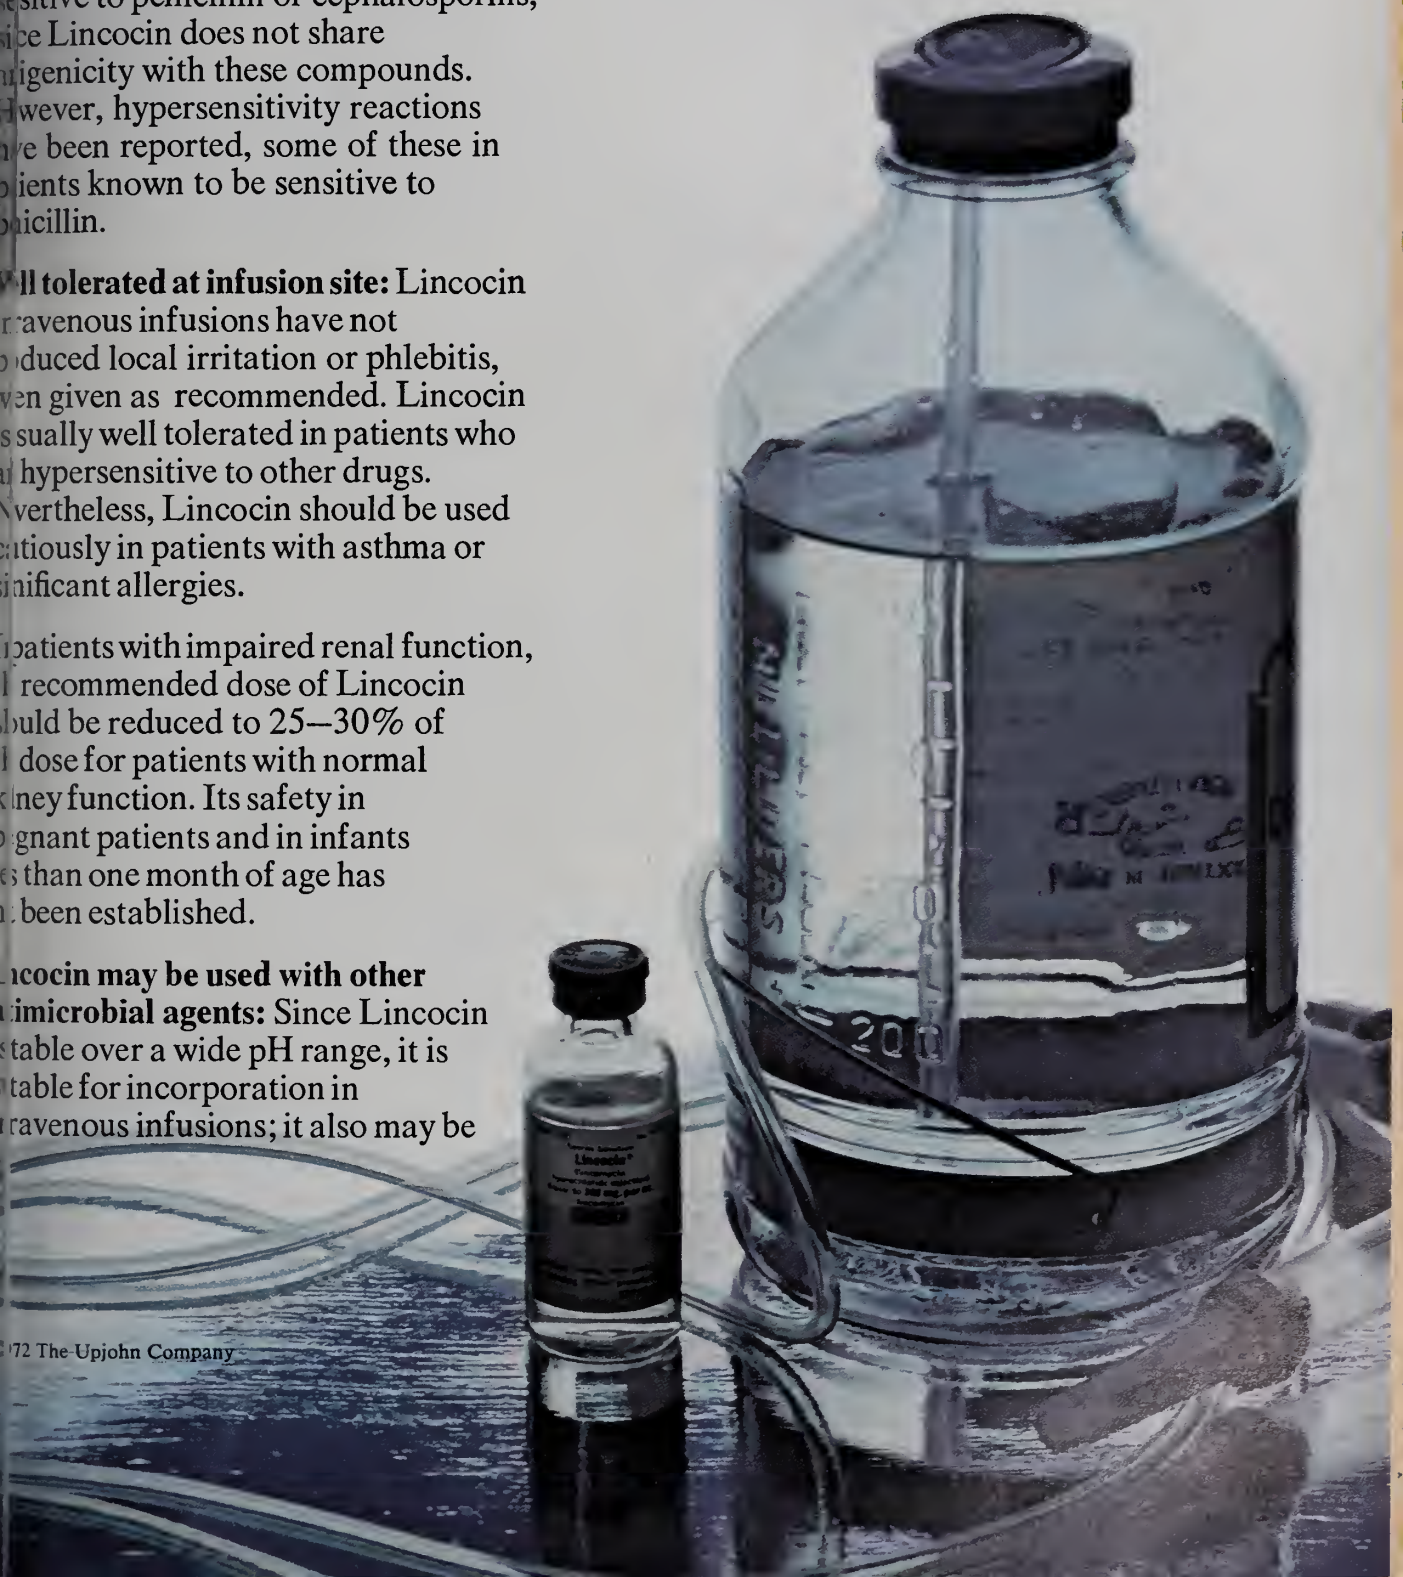
In usual IV doses, Lincocin (lincomycin hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water. But when 4 grams or more per day is given, Lincocin should be diluted in not less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

nections caused by susceptible strains
pneumococci, streptococci, and
staphylococci, including penicillin-
resistant strains. Staphylococcal strains
resistant to Lincocin (lincomycin
hydrochloride, Upjohn) have been
recovered. Before initiating therapy,
culture and susceptibility studies should
be performed. Lincocin has proved
valuable in treating patients hyper-
sensitive to penicillin or cephalosporins,
since Lincocin does not share
antigenicity with these compounds.
However, hypersensitivity reactions
have been reported, some of these in
patients known to be sensitive to
penicillin.

Well tolerated at infusion site: Lincocin
intravenous infusions have not
produced local irritation or phlebitis,
even given as recommended. Lincocin
is usually well tolerated in patients who
are hypersensitive to other drugs.
Nevertheless, Lincocin should be used
cautiously in patients with asthma or
significant allergies.

In patients with impaired renal function,
the recommended dose of Lincocin
should be reduced to 25–30% of
the dose for patients with normal
kidney function. Its safety in
pregnant patients and in infants
less than one month of age has
not been established.



**Lincocin may be used with other
antimicrobial agents:** Since Lincocin
is stable over a wide pH range, it is
suitable for incorporation in
intravenous infusions; it also may be
administered concomitantly with other
antimicrobial agents when indicated.
However, Lincocin should not be used
with erythromycin, as *in vitro* antagonism
has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

'72 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatment. *Skin and mucous membranes*—Skin rashes, urticaria, vaginitis, and rare instances of exfoliative and vesiculobullous dermatitis have been reported. *Liver*—Although no direct relationship to liver dysfunction is established, jaundice and abnormal liver function tests (particularly serum transaminase) have been observed in a few instances. *Cardiovascular*—Instances of hypotension following parenteral administration have been reported particularly after too rapid IV administration. Rare instances of cardiopulmonary arrest have been reported after too rapid IV administration. If 4.0 grams or more are administered IV, dilute in 500 ml of fluid and administer no faster than 100 ml per hour. *Special senses*—Tinnitus and vertigo have been reported occasionally. *Local reaction*—Excellent local tolerance demonstrated to intramuscularly administered Lincocin (lincomycin hydrochloride). Reports of pain following injection have been infrequent. Intravenous administration of Lincocin 250 to 500 ml of 5% glucose in distilled water or normal saline has produced no local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500 mg* Capsules—bottles of 24 and 100. *Sterile Solution, 300 mg per ml*—2 and 10 ml vials and 2 ml syringe. *Syrup, 250 mg per 5 ml*—60 ml and pint bottles.

Radiology and the Health Care Problem

JOHN A. CAMPBELL, M.D.

"The guest can better judge the feast than the cook"—Aristotle

NO SINGLE LEVEL of our medical system is untouched by the push toward change. The call for change is motivated in five basic areas: people, money, medical facilities, doctors, and medical education. All of these affect radiologists.

People Problems

An ever enlarging group of citizens are obsessed with the fact that in the world's richest society which spends $400 per person annually on defense and only $13 per person on health, there are millions of citizens unable to obtain a reasonable level of medical care at reasonable costs.

Dr. John Knowles[1] of Massachusetts General Hospital dramatizes this in the following statements: "The financial gap is considerable when one realizes that there are 45 million of our 200 million population who qualify as poor with incomes of less than $4345 per year for a family of four. About 25 million of these 45 million impoverished citizens are living in cities, and the other 15-20 million still live in suburban or rural areas. The quality of their lives is marginal at best and their health precarious. Lack of adequate nutrition, schooling, jobs, housing, civil rights and transportation limits their ability to achieve health care in the fullest sense of the word. Lack of health education along with financial and geographic barriers which limit access to physicians and health institutions deny them the necessary medical services received by the other 155 million people of the country. As our per capita cost of hospitals, doctors, and drugs increases, more of the marginal group are driven into further medical indigency, and more of the middle class people join in their plight. When more and more people wonder why they have such difficulty getting the excellent care which we have developed, something is apt to happen, and let's hope it doesn't require a destructive type of confrontation that denial of other preceived rights have produced lately." Economist Pollack[2] goes a step further and feels that all or virtually all Americans are now to be considered medically indigent, and that some form of indemnification for all has become a necessity.

There is another factor. Medical care is no longer regarded as a privilege. Health is considered as much a human right as is education. Yet medicine is the only big business where the consumer has no control over what he buys. Since health care is a tight monopoly, it seems destined to become a public utility and we will obviously need to accept regulations to develop the proper social-scientific institution capable of meeting whatever goals are desirable. We can ill afford to defend the status quo on the grounds that health insurance based on group practice or prepayment plans is the opening wedge for government control of medicine. In fact, it is the surest safeguard against such an eventuality.

We radiologists have not really defined our goals of health care. Can we continue our pursuit of excellence and deliver good radiology to all the people? Or will we need to accept mediocrity to some extent? There is need for research in developing simplier, faster, and more available radiological services to patients and physicians alike. One idea is to eliminate out-patient services in hospitals and having practicing radiologists of the community furnish these in offices and multipurpose regional clinics. Another is home health care as a substitute for some hospital care, but including basic radiologic and laboratory work done by shuttle vehicles.

The shortage of radiologists must be met by

The 37th Russell D. Carmen Lecture, delivered at the 1971 Minnesota Radiological Society Fall Meeting, September 17-19, 1971, Brainerd, Minnesota.

Dr. Campbell is Chairman, Department of Radiology, Los Angeles County-Martin Luther King, Jr. General Hospital, 12012 Compton Avenue, Los Angeles, California 90059. Formerly Chairman, Department of Radiology, Indiana University Medical Center, Indianapolis, Indiana.

See editorial, page 821.

the more liberal development of paramedical personnel and other schemes to increase the efficiency of those available. The radiologist should participate in the better distribution of radiologic care throughout the community by taking responsibility for certain population or geographic areas, offering services to deprived areas, and developing cooperative types of coverage. He should make a stronger effort to recruit as trainees in service programs blacks, the poor, foreign born and others not like himself. At Indiana University, I have utilized an increasing number of uneducated, hard core unemployed, with great success in jobs as orderlies, housekeeping, equipment maintenance, and technician assistants. Because of advanced age, alcoholism, and no previous employment records, these people were rejected by our employment office, and hired only as my personal responsibility. I have found them more compassionate with patients than younger employees, to have better attendance records, and to be tremendously grateful and loyal. Only one has dropped out, and two have advanced into more responsible departmental jobs. Employment of these persons is well worth the efforts required, and constitutes a form of community health care in itself.

Money Problems

Total health care expenditures in the United States will rise from 60 billion to 65 billion by the end of 1970 and to over 100 billion by 1975 to become the nation's biggest industry. Of this 60 billion, about two-thirds are generated in the private sector, and the remainder from government money. About 22 billion of the total or one-third of the health dollar is spent for hospital care, 12 billion for physician fees, and six billion on drugs. The average per capita cost of medical care in 1969 was $400, and the average patient's hospital bill $515. Health care presently accounts for 6% of our gross national product, and will consume 8 to 10% of all personal income by 1975.

Hospitalization costs are currently running as much as $100 per day in many places as compared with an average of $32 in 1960, and only $15 in 1950. If this rate of increase persists, costs of $500-$700 are predicted by the year 2000. Knowles[3] indicates that costs for intensive care beds at Massachusetts General Hospital are averaging $300-$500 per day now and could rise to $1,000 per day by 1980.

The predominant method of payment of medical care today is through third parties, meaning private, industrial, or government insurance. These will cover about one-third of patient medical expenses in 1970. One problem with them as pointed out by Dr. Eugene A. Stead, Jr.[4] is that the third party system does not provide an incentive for either the patient or physician to make costs less. Stead feels solutions for this must be new, and that they cannot come from reworking old institutions. He also feels that a national payment plan through Social Security is not going to work. The cost of medicare has increased from 3.2 billion to 8 billion, while medicaid from 1. to 5.5 billion since 1966. Pouring billions into the solution only forces costs upward and brings on more rebellion against them. He advocates that this problem be given the attention of economists, sociologists, and politicians in seeking a fresh creative solution. Another problem is that sickness or hospital insurance is not true health insurance, and covers only about 35% of the total medical expense, so that for chronic illnesses even the fully insured is in trouble. Moreover it furnishes too few benefits for office services, radiology, laboratory, and drugs outside the hospital.

One newer approach which is said to lessen over-utilization and unnecessary procedures, is the prepaid group practice plan. For hospitalization, insurance tallied 876 patient days per thousand subscribers as against 408 per thousand for the group practice plans, while for surgical procedures insurance showed a rate of 83 per thousand while prepaid groups had 31. For tonsillectomy the ratio was almost 8:1. Group practice and prepayment plans are growing, with about 2500 such multiple specialty groups now formed, some in big cities, some in small towns, some in hospitals, some in large medical centers, and some in a simple suite of doctors' offices. The combination of hospital based group practice with prepayment on a district basis in cities or regional basis in rural areas is said by Dr. Russell Lee[5] to be twice as efficient a way of delivering medical services as a present system of fee for service in the single doctor-patient pattern. It will probably take multiple systems to fulfill our needs, and some degree of competition between these may be in the patient's best interest. Radiologists should be free to select whatever scheme best

erves their effective role in the community, rather han by prescribed edict. The radiologist should lso increase his empathy for the patient by re-earching every conceivable means of improving ervice at less cost. Discipline in this area must e exercised whether or not fees are covered by hird parties.

Medical Facility Problems

Lee[5] has estimated that 30% of patients in a ospital at any one time should not be there. his over-utilization results from admissions for hat are really diagnostic procedures to gain nsurance, or the retention of patients past the cute stage of their illness. In addition, the ational shortage of 200,000 nurses has actually orced the closing of many hospital beds. All of hese problems affect hospital radiology depart-nents, causing peak loadings, uneven patient low, uneconomical emergency coverage and in-fficient equipment utilization. Radiologists have responsibility not to over-equip hospitals with liagnostic and therapy units for which there are oo few patients or no specialists who can use heir yield. We have many more cobalt units han we have available radiotherapists. Most of ll, radiologists have an obligation to work to eliminate unnecessary radiologic utilizations.

At Indiana University we have combined the radiotherapy facilities of five hospital units, and patients are shuttled to and from this depart-ment. We are suggesting combining the emer-gency services of these same hospitals (2000 beds) to avoid the costly duplication of equipment and on-call manpower. Patients destined for state, federal, county, or private units would be transferred to their respective hospitals after emergency services are completed. Teams of emergency physicians representing radiology, sur-gery, orthopedics, medicine and pediatrics will manage the emergency area around the clock. The service facilities of the other units will handle only elective radiology during regular hours. Radiologists should also tailor their serv-ices to expedite patient care and shorten both out-patient and in-patient stays. This may require abbreviated reports, reliance on paramedical peo-ple, staggering off-time to insure full services on week-ends. Finally the radiologist should employ broader use of systems analysis[6] in exploiting the tremendous technological advances to increase health manpower productivity and to improve the service yield of his department.

Doctors' Problems

Doctors deny responsibility for the patients' health care dilemma on the grounds of the physician shortage, excess patients, faulty patient attitudes, hospital policies, and the harrassment or interference from third parties. They point out that the problem is a reflection of the qualities of the consumption-oriented, impersonal society in which it develops; that doctors treat the poor with more common humanity than society as a whole; that if the physician makes a good income is he not merely doing something that is praised in every other line of endeavor? These arguments are true. Yet the public counters with equally logical questions. Should the physician not be urging his organizations to liberalize their views on socio-economic matters? Do new delivery sys-tems really threaten the financial security of the doctor? Or is his security more jeopardized by a society deprived of a better delivery system? It is difficult to be objective about a problem in which one has a vested interest, so radiologists should welcome the participation of the con-sumer, policy makers, and other experts. We should welcome the exposure of our inadequacies if we sincerely wish to correct them.

Radiology personifies the manner in which atomization of the huge body of medical knowl-edge today has made doctors inextricably depend-ent upon each other to produce good medical care. Doctors prefer to practice where there is good radiology. Hence a better supply and dis-tribution of radiologists is one of the keys to the better distribution of health care. With a short-age of radiologists, the centralized type of medical care predominates. Adequate numbers backed by paramedical teams could break one of the bottle necks of care distribution.

Educational Problems

The development of primary, first contact, continuing medical care is commanding the energy and priority of nearly every medical school in the nation today as it seeks to meet public de-mands for physicians. The university has the compelling responsibility to develop the basic science of health care hand in hand with educa-tion. Health care research is the evaluation of the outcome of such endeavors. Haggerty[7] has likened this field to the task of trying to put a river bank on a swamp. Medical schools face staggering financial problems and the galloping

advance of technology contributes to these.

As pointed out by Spellman,[8] medical students have recognized earlier than many of us one of the fundamental phenomena of our society. This is the observation that within the academic community, the medical school stands at the interface between the revolutionaries and the designated beneficiaries of their fervor, the poor and the black. Dr. Martin Cherkasky, Director of Montefiore Hospital, adds: "there is now a substantial number of medical students who don't put economics above everything else. These young people want to find in their profession a social commitment as well as a decent living. They are beginning to force changes in the curriculum. They don't think that molecular biology is more important than people."

During the past decade drastic curriculum changes have been made aimed at a greater production of graduates. Indiana University is embarking on a plan to eventually double its present enrollment of over 225 students per class by utilizing other university-community-hospital complexes in the state. The biomedical facilities of other universities in the state will be used to teach core groups of 50 first year medical students. These groups will transfer to the Indiana University medical school during the second and third years to finish core training and select specialty tracks, return to their satellite school for a fourth clinical year. All of these programs give a much needed flexibility to medical education and for the first time will permit students a choice of pathways or tracks through medical school.

Medical students will graduate with highly specialized and differentiated educations. The young prospective radiologist may have two full years of course work in radiology beyond time alloted to these subjects in the core curriculum by the time he graduates. These students are obviously unsuited for the medical graduate programs currently offered. They would not only be able to by-pass the internship and enter directly into residency, but with advanced education they will no longer need the three or more additional years as residents. This period could be shortened considerably. Indeed it may be advisable for residency programs to have no set length but be flexible enough to allow the usual variations in preparation and competence. The certifying boards would specify the curriculum requirements of such track students, and determine their competence for practice by examination. Carrying this a step further, the granting of state or national license to practice could be automatic on receipt of board certification and regulated only on the basis of opportunity.

Another source of manpower in medicine are the graduates of foreign medical schools, many of whom are the growing numbers of students rejected for admission to U.S. schools. Some 3000 Americans, equivalent to seven averaged sized U.S. medical schools are currently enrolled in foreign schools. We have 40,000 foreign educated physicians practicing in the U.S. today. In 1966-67, the number of foreign medical graduates, many of them U.S. citizens entering this country outnumbered graduates of U.S. schools 8540 to 7743. This indicates no shortage of potential applicants for expanded U.S. schools.

It is hoped that these track programs will permit schools to vastly increase their number of graduates. At the same time, there is great need to develop clinical support systems in the form of paramedical assistants. These range from formal university programs to apprenticeship-like instruction of selected candidates who usually possess certain basic qualifications in the medical field such as military corpsmen, radiologic technology, or nursing education. One important advantage of apprentice-type training is that it can be carried out in any radiologist's office. Our own experience has been to train our advanced radiologists to be administrative assistants, librarians, coding and retrieval personnel, photographic illustrative technologists, and special procedure technologists in gastrointestinal, chest, angiography, and urography.[11] These assistants actually perform all or part of the entire technical procedure thus releasing the radiologist to give more of his time to consultation and diagnosis. Others have trained technological assistants in the actual preliminary interpretation of roentgenograms of certain areas which lend themselves to the decision tree-type of interpretive approach as devised by Tuddenham.[12] In this way technologists can presort films of the chest, gallbladder, colon, and skeletal systems into normal and abnormal groups and thus simplify secondary readings by radiologists.

Another extension of the core track type of

nedical education is the concept of endless con-inuing education for the graduate. This would ›e achieved by requiring the radiologist to return o medical school in a full-time refresher-teaching ·ole periodically in order to sustain his licensure. During this sojourn at the school his practice would be continued by an advanced resident or ›ther faculty member. Many of these changes in he production of health professionals call for ong overdue revision and updating of our licen-sure laws. License to practice medicine should ›e based on competence in field examined, and he bottlenecks of credential requirements should ›e eliminated.

Conclusions

The radiologist cannot possibly escape the coming confrontation with the people seeking an improvement in the delivery of health care. The answer is change, and the radiologist must help to shape it.

He must work to make his services more available to people, to help solve the problems of cost, to prevent the over-utilization of radiologic procedures, to transfer out-patient services from hospitals to other community facilities, to help teach radiology to more students and health professionals, to create effective community-wide emergency services in radiology, to facilitate the broader development of paramedical personnel, and to be less competitive and more cooperative with others in the field.

This may well be the opportunity for the radiologist to discard many of the anachronisms of the past. Certainly the cure would seem less painful than the disease.

University of Minnesota

Course on Recent Advances In Infectious Diseases

The Department of Medicine and the Office of Postgraduate Medical Education of the University of Minnesota announce a course "Recent Advances in Infectious Diseases" to be held at the Mayo Memorial Auditorium on the Minneapolis Campus October 12 to 14, 1972 in honor of Wesley W. Spink, Regents' Professor of Medicine and Comparative Medicine.

The course will offer recent information on detection, management and prevention of serious infectious diseases in man. It will include a broad view of the biology of infectious agents and host responses. Several related clinical problems in each of five general topics will be reviewed in depth. Topics will include Gram-negative Sepsis, Pyogenic Infections, Zoonoses, Respiratory and Streptococcal Disease and Immune Deficiencies. There will be time for questions and several panel discussions. The course is designed for physicians engaged in the practice of general medicine and the clinical management of infections in children and adults. The tuition is $125.00. Residents and fellows-in-training $80.00.

Further information may be obtained from James M. Schless, M.D., Director, Postgraduate Medical Education, University of Minnesota Medical School, Minneapolis, Minnesota 55455.

Minnesota Health Professionals Honor Congressman Ancher Nelsen

CONGRESSMAN ANCHER NELSEN was honored for his efforts and leadership in the area of health legislation by Minnesota health science professionals at a special appreciation dinner on July 31, 1972. About 500 men and women representing medicine and other health related fields attended the bipartisan affair which was held at the Radisson South Hotel in Bloomington.

Speaking at the dinner was HEW Secretary Elliot L. Richardson who praised Congressman Nelsen for his efforts in influencing the passage of sound health care legislation. Richardson stated "his (Nelsen's) influence and prestige on Capitol Hill springs not from headline grabbing flamboyancy, but from patient, constructive and above all tireless work."

Nelsen is currently serving his seventh term in Congress representing Minnesota's Second District, and is the ranking Republican on the Public Health and Environment Subcommittee of the House Interstate and Foreign Commerce Committee.

Another speaker, Congressman Paul G. Rogers (D), Florida, and Chairman of the Public Health and Environment Subcommittee, gave high praise to Nelsen and stated: "he is doing a magnificent job."

Doctor Lyle French, Vice President for Health Sciences, University of Minnesota, served as Dinner Chairman and Doctor Ray Pruitt, Dean of the Mayo Medical School, acted as Master of Ceremonies.

Other headtable guests included: John Zapp, D.D.S., Assistant Secretary, Department of HEW, MSMA President George B. Martin, M.D. and Mrs. Martin and representatives of other sponsoring organizations.

Congressman Nelsen's daughter, two sons and their spouses, and his sister attended as special guests.

Joining the Minnesota State Medical Association in this recognition dinner for Congressman Nelsen was the Minnesota Nurses Association, Minnesota Dental Association, Minnesota State Pharmaceutical Association, Minnesota Hospital Association, Minnesota Veterinary Medical Association, Mayo Medical School, Mayo Foundation and the University of Minnesota Health Sciences.

Harold W. Brun
Executive Secretary
Minnesota State Medical Association

HEW Secretary, Elliot L. Richardson, was a featured speaker at the recognition dinner given Congressman Ancher Nelsen by the Minnesota State Medical Association and other health related organizations. Seated to the right of Secretary Richardson is Mrs. French, wife of Doctor Lyle French, Vice President for Health Sciences, University of Minnesota, who served as Dinner Chairman.

Representative Ancher Nelsen (center), Minnesota's Second District Congressman, is pictured here with MSMA President, Doctor George Martin (left) and MSMA President-elect, Doctor John J. Regan (right), during the social hour preceding the testimonial dinner given Congressman Nelsen on behalf of the Minnesota health science professionals.

Doctor Lyle French (right), Vice President for Health Sciences, University of Minnesota, is shown presenting a special appreciation plaque from the health science professionals to Congressman Ancher Nelsen. Also receiving a special recognition plaque from Doctor French was Congressman Paul G. Rogers (D), Florida, Chairman of the House Public Health and Environment Subcommittee, who spoke at the dinner.

St. Mary's Physician Receives Award

Dr. John Warren, Golden Valley, was named recipient of the first annual Leonard A. Lang Obstetrics and Gynecology Teaching Award. The citation and cash award is given for excellence in teaching obstetrics and gynecology to a practicing physician who is a member of the clinical faculty of the University of Minnesota Ob Gyn Department. Dr. Warren is a member of that faculty, and teaches residents assigned by the University to St. Mary's Hospital for clinical experience in Ob Gyn.

The award is sponsored jointly by the Department of Ob Gyn at the University of Minnesota and by St. Mary's Hospital and was established in honor of Leonard A. Lang, M.D. clinical professor emeritus at the University of Minnesota and chief emeritus of the Ob Gyn service at St. Mary's.

Upstate Minnesota Physician Appointed Associated Editor of Modern Medicine

Dr. Stephen L. Zuckerman, a Diplomate of the American Board of Internal Medicine and a resident of Onamia, Minnesota, has been appointed an associate editor of MODERN MEDICINE.

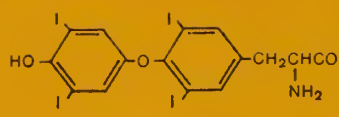
Dr. Zuckerman is co-ordinator of health sciences education for the Tri-Hospital Association, consisting of St. Joseph's Hospital, Brainerd; St. Gabriel's Hospital, Little Falls, and Community Mercy Hospital, Onamia. He serves as consulting internist to all three institutions, and is a clinical assistant professor of medicine at the University of Minnesota.

THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID® (sodium levothyroxine) THERAPY

- No calculations are needed, test interpretation is simple
- P.B.I., T_4 by Column, Murphy-Pattee, Free Thyroxine are all useful in monitoring patients on T_4 because they *all* measure T_4
- SYNTHROID patients are thereby easy to monitor because their test results will fall within predictable, elevated test ranges
- Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T_4 By Column	Less than 3 mcg %	7-9 mcg %
T_3 (Resin)	Less than 25%	27-35%
T_3 (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5* nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

Synthroid®
(sodium levothyroxine)



Choose the Smooth Road ...to thyroid replacement therapy

See reverse side for Prescribing Information.

Synthroid® (sodium levothyroxine)

brand of Sodium Levothyroxine, U.S.P. • Synthroid Tablets—for oral administration • Synthroid for Injection—for parenteral administration

SYNTHROID Tablets and SYNTHROID for Injection contain synthetic crystalline sodium levothyroxine. L-thyroxine is the metabolically active isomer secreted by the thyroid gland and is approximately twice as active as the racemic (DL-) form. For purposes of comparison, 0.1 mg. of SYNTHROID (sodium levothyroxine) elicits a clinical response approximately equal to that produced by one grain (65 mg.) of desiccated Thyroid, U.S.P. SYNTHROID (sodium levothyroxine) simulates endogenous thyroxine in its gradual, sustained effect—an important consideration from the standpoint of maintenance—and in its high specificity for serum-thyroxine-binding protein. In contrast to desiccated thyroid and thyroglobulin, each dose of SYNTHROID (sodium levothyroxine) is uniform in hormone content, thus avoiding fluctuation in biologic potency and consequent treatment problems. SYNTHROID (sodium levothyroxine) permits maximal toleration because of its complete freedom from potentially allergenic protein substances.

Sodium Levothyroxine

Pharmacology: SYNTHROID (sodium levothyroxine) acts, as does endogenous thyroxine, to stimulate metabolism, growth, development and differentiation of tissues. It increases the rate of energy exchange, and increases the maturation rate of the epiphyses. Sodium levothyroxine is absorbed rapidly from the gastrointestinal tract after oral administration; following absorption, the compound becomes bound to the serum alpha globulin fraction. Accurate determination of either the PBI (protein-bound-iodine) or other appropriate tests may serve as a useful index of therapeutic response to SYNTHROID (sodium levothyroxine) therapy because of its affinity for serum proteins. The mean half-time of levothyroxine turnover is reported to be 6.5 days as measured by disappearance of radio-iodine (I^{131}) labeled levothyroxine from the serum in euthyroid subjects.

Indications: SYNTHROID (sodium levothyroxine) is specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or anti-thyroid drugs. Indications for SYNTHROID (sodium levothyroxine) Tablets include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (non-toxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) for Injection is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdosage of SYNTHROID (sodium levothyroxine) may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting, and continued weight loss. While these effects may begin after four to five days, they may not become apparent for one to three weeks. Patients receiving the drug should therefore be kept under close observation for signs of thyrotoxicosis. If indications of overdosage appear, the medication should be discontinued for two to six days and then resumed at a lower level. Signs of optimal thyroid function will establish the proper maintenance dose.

The severity of diabetes may be reduced by hypothyroidism, and the requirement for insulin is often lowered. Therefore, patients with diabetes mellitus should be observed closely for possible changes in insulin or other antidiabetic drug dosage requirements.

If hypothyroidism is accompanied by adrenal insufficiency, such as Addison's disease (chronic adrenocortical insufficiency), Simmond's disease (panhypopituitarism), or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The patient's progress during thyroid treatment must be observed carefully and regularly for evidence of the development of any of these conditions.

Caution must be exercised in the administration of this drug to patients with cardiovascular disease; development of chest pains or other aggravation of the cardiovascular disease requires a reduction of dosage.

Contraindications: SYNTHROID (sodium levothyroxine) therapy is contraindicated in thyrotoxicosis and acute myocardial infarction.

Side effects: The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism: sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction in dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and administration: The importance of careful diagnosis of hypothyroidism must always be considered, despite the fact that symptomatically the condition is one of the most clear-cut of endocrine disorders. Diagnosis should include laboratory testing of basal metabolic rate, serum PBI, and other tests for thyroid function to support clinical signs of thyroid hypofunction.

Treatment of hypothyroidism requires replacement of thyroid hormone in daily amounts adequate for maintaining normal metabolism. Reliable laboratory measurements and good clinical judgment will determine the daily dose required to achieve the goal of therapy. The correct concentration of thyroxine is essential for the health of all tissues; overdosage may lead to thyrotoxicosis medicamentosa, while underdosage permits the continuation of the hormonal deficiency.

Treatment can be guided by the serum PBI level (the normal range in males 4.5 to 7.5 mcg%; in females, 5.5 to 8.5 mcg%) produced after a few weeks the daily dose of thyroxine administered. A PBI level below 5 mcg% may indic the need for a larger dose of thyroxine. PBI levels are not absolute ind cators the thyroid state, however. In patients made euthyroid with SYNTHROID (sodi levothyroxine), it is not unusual to find PBI levels of 8 to 10 mcg% Levothyrox has a high binding capacity for serum proteins in contrast to other thyroid me caments which may contain varying amounts of L-triiodothyronine which ha low binding capacity.

In adult myxedema (when the PBI is often as low as 2.5 mcg% or less), starting dose of SYNTHROID (sodium levothyroxine) should be 0.025 mg da increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second weeks. A serum PBI, ECG, and clinical examination should be made after 30 d on this dosage regimen. In the event of an over-all rapid recovery the 0.1 daily dose should be continued, and the clinical status reviewed after an ac tional 30 days (total treatment period of approximately 90 days). The daily d may then be increased to 0.2 mg. After an additional two months on this regim clinical and PBI evaluations should be repeated. If either appears to be bel normal, the daily dose should be increased to 0.3 mg. Permanent ma intenar doses vary with the individual patient, ranging from 0.1 to 1.0 mg. da ly.

The same starting dose of SYNTHROID (sodium levothyroxine) as adm n ste for adult myxedema may be employed for cretinism or severe hypothyroid sm children, but all intervals of change should be made every two weeks. In growing child, final dosage requirements may be greater than in the adult. cases where cretinism is discovered after the first six weeks of life, overdos of SYNTHROID (sodium levothyroxine) therapy is much preferred to under-tre ment, in order to accelerate growth rate. As with the adult patient, serum may be measured during SYNTHROID (sodium levothyroxine) administration.

In hypothyroidism without myxedema (where the PBI usually ranges from to 4.5 mcg%), the starting dose of SYNTHROID (sodium levothyroxine) may 0.1 mg. daily and may be increased by 0.1 mg. every 30 days. Clinical eval at should be made monthly and PBI measurements about every 90 days. Final ma tenance dosage will usually range from 0.2 to 0.4 mg. daily, although h gl maintenance dosages are sometimes necessary.

In myxedematous stupor or coma, with no evidence of severe heart d sea 200 to 400 mcg. of SYNTHROID (sodium levothyroxine) for Injection may administered intravenously utilizing a solution containing 100 mcg per Detectable effects are usually observed by the sixth hour after injection and fully appreciated during the following day. A repeat injection of 100 to 200 m may be given on the second day if significant improvement has not occ r The intravenous use of sodium levothyroxine in myxedematous coma is edva tageous because it produces a predictable increase in the concentration protein-bound iodine, eliminates the need for multiple doses until oral thera is reinstated, circumvents the uncertainty of oral or intramuscular absorpti and avoids the risk of pulmonary aspiration. SYNTHROID (sodium levothyrox for injection is given by the intramuscular route when the oral route is impra cal and a rapid onset of effect is not desired.

It should be noted that in some patients whose PBI is 4.0 mcg% or e endogenous secretion is reduced when exogenous thyroid hormone is adm n tered. In these patients, the PBI does not increase as would be expected af a few weeks of medication. This may indicate the need for a longer period observation to ascertain the required dosage. In such patients, several mont may be needed to determine the correct maintenance dosage.

How supplied: SYNTHROID (sodium levothyroxine) Tablets are supplied scored, color-coded compressed tablets in seven concentrations 0.025 m (orange), 0.05 mg. (white), 0.1 mg. (yellow), 0.15 mg. (violet), 0.2 mg. (pin 0.3 mg. (green), and 0.5 mg. (blue).

SYNTHROID (sodium levothyroxine) for Injection is supplied in 10 ml. vi containing 500 mcg. of lyophilized active ingredient and 10 mg. of Mannitol N. a 5 ml. vial containing Sodium Chloride Injection, U.S.P., is provided as diluen

Directions for reconstitution: Reconstitute the lyophilized sodium levothyroxi by aseptically adding 5 ml. of the Sodium Chloride Injection, U.S.P., to the vi Shake vial to insure complete mixing.

Use immediately after reconstitution. Discard any unused portion.

Psychiatry

Hysterical Neurosis

Conversion Type

ABRAHAM FLEMENBAUM, M.D.

Conversion hysteria is of clinical interest because of its striking and dramatic manifestations. There has been lack of agreement concerning definition of terms and the criteria for diagnosis; however, in its "classical" form it is a disorder diagnosed in the presence of the following characteristics: The patient is generally a young adult, usually female, with fixation in an early stage of psychosexual development, frequently with a premorbid personality of the "hysterical" kind. These patients, in the presence of a precipitating stress, usually of a sexual nature, "convert" their anxiety into somatic symptoms symbolizing psychological conflict.

Because anxiety is "converted" the patient presents *belle indifference* and this avoidance of anxiety by symbolization provides a very important primary gain. By obtaining attention, care, love, etc., from the family, the hospital personnel, and others, the patient receives also a secondary gain. The symptoms are usually expressed in the voluntary sensori-motor nervous systems, and therefore, originally were thought to be completely different from the psychophysiological reactions which were supposed to be expressed only in the "autonomic" nervous system.

As preferred defense mechanisms these patients use denial and repression.

Somewhat different clinical pictures, however, have evolved, probably related to the increased sophistication of medical knowledge of the patients.

Among these "newer" clinical pictures, some of which are well known and accepted, are the "compensation" neurosis, conversion symptoms "simulating physical illness," and symptoms "complicating physical illness."

There are other discrepancies in the "classical" picture. They stem from observations that patients with conversion hysteria frequently had fixations and personalities other than hysterical. They also stem from the fact that in some patients the symptoms were not clearly voluntary sensori-motor (i.e. nausea, vomiting, abdominal pain, etc.). It has also been found that under hypnosis and other conditions some autonomic functions can be affected. The cleavage between autonomic and voluntary sensori-motor nervous systems then is not so clear. "Conversion hysteria" is not a single disease but a syndrome consisting of at least two different disorders, (not including "compensation neurosis," childhood hysteria, or hysteria "complicating a physical illness"). For lack of a better name these disorders are here called Type I or "classical" and Type II or "reaction formation".

Clinical Observations: Similarities and Differences

The American Psychiatric Association's *Diagnostic and Statistical Manual II* defines hysterical neurosis, conversion type (300.13) as one in which:

> "the special senses or voluntary nervous system are affected, causing such symptoms as blindness, deafness, anosmia, anaesthesias, paraesthesias, paralyses, ataxias, akinesias, and dyskinesias. Often the patient shows an inappropriate lack of concern or belle indifference about these symptoms, which may actually provide secondary gains by winning him sympathy or relieving him of unpleasant responsibilities. This type of hysterical neurosis must be distinguished from psychophysiologic disorders, which are mediated by the autonomic nervous system; from malingering, which is done consciously; and from neurologic lesions, which cause anatomically circumscribed symptoms."[1]

Reports of clinical observations and erratic results obtained with treatment made it obvious that this picture of "classical" hysteria is not satisfactory for most cases of "hysteria". Clinical findings have shown that patients with these types of symptoms may later regress to full blown schizophrenia; this has been well known and has been frequently reported.[3,9,10,17,18,20,21]

Dr. Flemenbaum is a Research Fellow at the Adult Inpatient and Clinical Psychopharmachology Services, Department of Psychiatry, University of Minnesota, Minneapolis.

This report is a modified version of a paper which received an honorable mention in the William C. Menninger Award of 1970, when Dr. Flemenbaum was Senior Resident.

An intriguing fact is the extraordinarily consistent choice of inadequate and frequently abusive husbands. These husbands also show a high incidence of alcoholism and other sociopathy. Both of these facts have been reported by Blinder[2] and Slater.[17] It has also been reported recently by Guze that among relatives of convicted criminals there is an increase of conversion hysteria.[7]

A more sophisticated society does not tolerate "classical" hysteria. There is a decrease in it, but with compensatory increase of pictures characterized by pain, usually in the abdomen or head, and disorders "simulating physical illness".[21] This has changed either the picture of classical clinical conversion or its frequency to such a point that now many patients are referred to psychiatry only after expensive and extensive medical and neurological work-ups, after multiple hospitalizations, often when the patient has had innumerable operations (and abdomens that have been called "battle ground or checker board abdomen"), or is "hooked" on pain medication. The "classical" picture of conversion is infrequently seen now and almost exclusively is related to extreme environmental deprivation, rigid religious education, related to mental retardation, or as symptoms of an incipient schizophrenia.

Several authors tend to consider hysteria conversion as more of a syndrome than a specific disease entity for these reasons: multiple ethiology; neurosis, schizophrenia, endogenous depression; variety of clinical pictures; "classical vs. preschizophrenic vs. polisymptomatic.[12,13,17]

Even with all the differences in clinical manifestations of patients with the "syndrome", most articles and textbooks still recommend making the diagnosis on the basis of positive findings and not only when physical disorder has been ruled out. These positive findings include: a history of symptoms (past or concurrent) that clearly appear conversive, such as paralysis and anesthesias; other psychoneurotic symptoms such as anxiety, depression, obsession phobias; a past history of multiple illness or multiple surgery with no clear cut physical origin; a history of sex disturbances with frigidity and/or distaste for sexuality; behavior manifestations of hysterical personality; the presence of *belle indifference;* a history of recent death of a person important to the patient or similar disturbances in personal relatives temporarily related to the onset of the symptoms.[11]

As can be seen here, even though these diagnostic characteristics of the disorder include "modified" ones, they are still "classical" in that the patient has to have some hysterical personality characteristics or other classical symptoms of conversion (*belle indifference,* neurotic symptoms frigidity and/or distaste for sex, etc.).

The other side of the coin in the problem of definition of hysteria is represented by Robbins, Perley, and Guze. These authors developed a definition of the clinical picture of hysteria after the findings of Purtell, et al.,[13] of a "characteristic clinical picture of women with a diagnosis of hysteria" in which (a) they had at onset an age of less that 35 years; (b) the disorder was seen rarely or not at all in men; (c) it was never monosymptomatic (minimum of 11 symptoms per patient); (d) vague, unclear complaints; (e) a history of excessive hospitalizations and surgery, (f) and sexual frigidity and/or dysmenorrhea, dyspareunia, etc.

With these findings Robbins and O'Neal suggested specific clinical criteria,[16] that, slightly modified by Perley and Guze[12] and then again modified by Guze, et al.,[5,6,7] are presented as follows:

1. The patient has to present a dramatic or complicated medical history before age 35.
2. The patient has to report at least 25 of the following symptoms, in at least nine of the ten groups of symptoms:

   Group 1: feeling sick most of one's life, headache
   Group 2: blindness, paralysis, anaesthesia, aphonia, fits of convulsions, unconsciousness, amensia, deafness, hallucinations (in the absence of psychosis) or urinary retention;
   Group 3: fatigue, lumps in the throat, fainting spells, visual blurring, weakness, dysuria
   Group 4: breathing difficulty, palpitation, anxiety attacks, chest pain, dizziness;
   Group 5: anorexia, weight loss, marked fluctuation in weight, nausea, abdominal bloating, food intolerances, diarrhea or constipation;
   Group 6: abdominal pain or vomiting;
   Group 7: dysmenorrhea, menstrual irregularity including amenorrhea of at least two months excessive menstrual bleeding;
   Group 8: sex indifference or frigidity, dyspareunia or other sex difficulties, hospitalization for hyperhemesis gradivarum or vomiting for all nine months of pregnancy;
   Group 9: back pain, joint pain, extremity pain burning pains of the sex organs, or of the rectum, other bodily pains;
   Group 10: nervousness, fears, depressed feelings

quitting work, inability to carry regular duties, easy crying, hopeless feelings, thinking of suicide and suicide attempts.

All these authors maintain, that not only course nd outcome but also diagnosis are highly unreliible, when using previous definitions contrasting /ith high (90% and higher) reliability of diagnois (and outcome) of hysteria when made with ieir own criteria.

At the University of Minnesota Hospitals, about 0 to 40 percent of the consultations are for "hysria" of a type similar to the patient described by uze, et al. but there are, however some differnces. These differences and similarities are as ollows: The patient is usually a middle aged emale. She has had a 15 to 20 year history of ain with a history of multiple operations and 10 o 20 hospitalizations with very extensive workips. She does *not* show *belle indifference;* on the ontrary, she has complained a great deal for many ears and has manipulated her family and her hysicians so well that she is already, or nearly, rug addicted. (See Table.)

These patients may also have hysteroid prenorbid personalities. Frequently "oral" dependncy is marked, but the patient has used reactionormation extensively, permitting her to appear a ard worker, reliable, and a self-sufficient individal. This continues until the symptoms become so intense, and pain so constant" that she "had o quit working" and stopped taking care of her esponsibilities.

Aside from the satisfaction of oral dependency eeds, no other primary unconscious conflict that ad to be symbolically "converted" can be found; herefore, in this type of patient, primary gain, f existent at all, is completely unimportant. The ttention, care, and love of the family, the hospital personnel, the physician, or the welfare worker, coupled with relief from unpleasant and/or unwanted responsibilities, make the so called secondary gain of the "classical" type become all important, to such a point that we can say that *the secondary gain becomes the primary gain* and vice versa.

Another difference in this type of patient when compared with the classical ones is that it is frequently impossible to find in the anamnesis any specific precipitating stress aside from the finding that responsibilities become too large (or the family stops paying attention to the patient for one reason or another) just before her symptoms flare up. For this reason we can say that another clear difference between these two types of hysteria conversion is in the area of conflict resolution. On the one hand, in the classical type, under stress the unconscious drives are converted by symbolization into physical signs. In the second type a hard working, independent patient, in no acute conflict, can, without losing face, abandon his/her responsibilities and get fulfillment of his/her dependency needs by somatization. This somatization is usually reinforced by the father or the husband who somehow obtains some gain with it.

Examples include a busy stock man who comes home several times during the day due to multiple complaints by his wife. In another case, an elderly husband, who had been ordered to rest after myocardial infarction was not only working in his job but would cook and do all the house chores for his wife was "incapacitated" by multiple pains.

Slater[17] also found some evidence of reinforcement of the somatic symptoms by members of the immediate family (which he was tempted to call a *"follie a deux"*). He noticed four cases in which at least one family figure, the father or the husband, was busily employed fostering the illness.

These patients often have family histories simultaneous in two extremes: some members of the family are either alcoholic or delinquents; others are "pillars of the community". They are the "all-American family" people, hard workers, PTA goers, taxpayers, "law and order" people, football players, which suggests the possibility of reaction formation again.

Another common observation in the psychiatric interview is a family history that is positive for somatization. "Imitation and identification", especially with significant members of the family, has been frequently reported.[11,17,21]

The somatization of these patients can simulate practically any medical disorder. Sydenham observed that "hysteria imitates almost every disease that befalls mankind." Sometimes the symptoms are even "shaped" with time by consultation with different physicians. Symptom patterns change with changing medical knowledge on the part of the patient and with his aculturation and sophistication.[21] Symptoms start relatively early in life but they may not interfere with the activity that the patient really enjoys (in extreme cases they may skate but won't cook).

Other Evidence in the Literature

These findings are consistent with the literature

as mentioned above.

With regard to hysteroid personality, even in the "classical" type, many studies[2,4,9,21] emphasized that hysterical personality is not a condition "sinequa non" for the diagnosis of hysteria conversion. Slater, for example, found in his study that only about one-fourth of the cases had hysterical traits, but some showed sexual interests that were both late and feeble and failure to marry was found in many cases, which can be a sign of hysterical traits.[17]

Referring to precipitating stresses the literature appears confusing. On one hand, are reports like the one by Barham.[1] He states that in a follow up of 100 patients with hysteria "precipitating factors were present in every case even though in a few cases they were fairly difficult to elicit."

On the other hand, Slater[17] found that in about one-half of his cases there was nothing he could "put his finger on"; in some cases the stresses were "banal" and in very few, stresses "could hardly have been effective save for a pre-existing hysterical predisposition."

Slater[18] found that of the final group of patients originally diagnosed as "hysteria" in which no underlying physical pathology could be found (21 patients), the seven patients that had the "typical" (classical?) conversion syndrome all had definite psychogenesis (precipitating factors?) for their disorder. The patients that have definite precipitating factors (which grossly correspond more to a description of the "classical" type than to the nonclassical type or type 2) have a better prognosis.

In Barham's study, 66% were well at the time of the follow up. A total of 83% were still functioning four to six years after discharge, most, without any psychotherapy at all. Slater[18] found that the seven patients that had "typical" conversion syndrome were all well on follow up even though "three of them had shown some tendencies to develop symptoms when stressed" (which was also true for some patients in Barham's study).

This good prognosis on follow up contrasts sharply with that of the patients diagnosed using the stricter diagnostic criteria. Ninety percent or more of these patients had a poor prognosis. In Slater's follow up,[18] for example, he found of the 21 patients in which no underlying physical pathology could be found, there were 14 patients who resembled our type 2; five of these patients were partially disabled, three were totally disabled, and the rest were also considered chronic cases.

It is well accepted that hysterical symptoms can be found in a multiplicity of disorders including schizophrenia.[1,2,3,4,5,6,9,10,12,17,18,20,21] There is however, an alarming, and in some papers almost unbelievable high, frequency of neurologieal disorders (and even death) discovered in the follow up studies.[5,6,12,17,18,20]

Most of these studies were done following patients discharged from *neurological* hospitals. In the study with the worst results,[20] a 25 year follow up was conducted on patients discharged from the Boston Psychopathic Hospital. Out of 66 patients 22 had psychotic diagnoses and 14 patients had died of "organic" disorders. We observed though that the diagnosis of "hysteria" was so freely given that three cases with delusions or hallucinations on admission were still diagnosed as such.

That there are "clinically different 'hysterias'" has been previously noted. Ziegler,[21] for example concludes that there are "four different clinical types of conversion reaction: (a) "classical" with "loss of function" or "hysteroepilepsy"; (b) simulation of known organic entities; (c) those in which body pain is prominent; (d) conversion symptoms intermingled with those of an organic and/or psychophysiological nature.

These four types of hysteria can be summarized in our two types: the classical and the nonclassical.

Guze[5,6] also differentiates between what he calls "hysteria", following his rather strict "medical" diagnostic criteria, and "conversion symptoms."

These "conversion symptoms" are not only monosymptomatic but rather "classical" like: amnesia, paralysis, aphonia, blindness, anesthesia, etc., and he specifies that they are the so-called "pseudoneurological or grand hysterical symptoms" but probably because of anti-analytieal biases no other diagnostic criteria were used. They were referred to as unexplained symptoms suggesting neurological disease."

If diagnosis of "conversion" symptom was not given so freely and if the diagnostic criteria as summarized above (including psychoanalytical concepts of symbolization, primary and secondary gain, *belle indifference*, etc.) were used to make the diagnosis, many patients diagnosed in the follow up as schizophrenic personality disorders, neurological disorders, etc., would probably have been ruled out.

Summary

Two extremely different types of hysteria have been described in the literature; one "classical" using psychoanalytical concepts by the author and Guze et al. using only "medical" concepts. The author proposes a third type in middle ground using both psychoanalytical and medical concepts (probably includes Guze's type) and the diagnostic characteristics are summarized in the Table.

TABLE
Hysteria Conversion

Characteristic	Type I "Classical"	Type II "Reaction-Formation" Hysteria
Age	Adolescent-young adult	Usually middle aged
Sex	More frequently female	Almost always female
Premorbid Personality	Hysteroid?	Oral dependent
Psychosexual Dynamics	Oedipal fixation	Pre-genital fixation—Oral?
Environmental Precipitating Factors	Present - sexual?	Not present—satisfaction of dependency needs
Family History	Hysteria may or may not be present—family is usually religious, unsophisticated, from small towns, etc.	Hysteria frequently present—alcoholism and delinquency are frequent or the family is extremely conventional, rigid (a reaction formation?)
Conflict Resolution	By symbolization "conversion"	Satisfaction of dependency needs—relief from responsibilities
Most Used Defense Mechanism	Denial—repression	Reaction-formation?
Primary Gain	Most important	Minimal—may not be present
Secondary Gain	Secondary	Becomes the primary (most important)
Belle Indifference	Present "obvious clinically"	Not present or weak "You have to search for it"
Symptom Expressed Through . . .	Voluntary sensori-motor plus nausea, vomiting hiccups, etc.	Abdominal pain, back ache, headache, bizarre disease picture
Frigidity	Present	May be totally absent
Number of Symptoms	Monosymptomatic	Multiple
Complaint	Localized, precise	Vague, multiple
Polisurgery Polihospitalization	Not present	Present
Response to "Suggestion"	Fair to very good	Very poor

GENERAL PRACTITIONER to join 2 man group, family practice. Busy, well established location in town of 2000 with drawing area 10,000. Excellent schools, churches, golf club, hunting and fishing, 65 miles from Twin Cities. Completely equipped and staffed clinic. New 40-bed hospital, accredited. Salary arrangements to start and early partnership. Write MINNESOTA MEDICINE, Box 465, 375 Jackson St., St. Paul 55101.

BAYPORT, MINNESOTA—Ideal location for general practitioner. Partially equipped office, two blocks from St. Croix River. Fully accredited hospital three miles away. Site of Andersen Corp., largest wood window manufacturer employing 1600. Retired physician practiced 48 years in Bayport. Physicians in nearby community will backup physician for any vacation time or attendance at meetings, etc. Excellent potential for one or two physicians. Contact: Keith R. Clements (612) 439-5195.

GENERAL PRACTITIONER—County seat community of 2000. Modern 35 bed hospital 4 blocks from fully equipped clinic. Present associate retiring January 1, 1973. Early partnership. Contact H. A. Knoche, M.D., Gaylord, Minnesota 55334. Telephone 612-237-2528.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

GENERAL PRACTITIONER to join young 5 man family practice group. College town of 7,000 serving approximately 20,000 population. Accredited hospital with specialist consulting staff. 30 miles from St. Paul-Minneapolis, Minnesota. Contact R. M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone (715) 425-5322.

GENERAL PRACTITIONER needed for an extremely busy rural practice in Northern Minnesota. Excellent hospital and clinic facilities. Starting salary of $25,000.00 with possible early partnership. Write MINNESOTA MEDICINE, Box 466, 375 Jackson, St. Paul, Minn. 55101.

PSYCHIATRIC RESIDENCIES—Excellent, approved psychiatric education; intellectually demanding and clinically diversified in a stimulating, well-balanced program. Affiliated with Michigan State University's College of Human Medicine. The setting is in a culturally rich community; the serene, scenic Grand Traverse Bay area. Three year plan: $12,820 to $14,574; Five year plan: $14,637 to $27,436. Contact Dr. Paul E. Kauffman, Director of Psychiatric Training, Room 166, Traverse City Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

GENERAL PRACTITIONER—Excellent location in the Lost Pines of Texas area, growing community of 3,500 along the beautiful Colorado River. Has an excellent opportunity for a good family General Practitioner. Excellent small hospital (25 beds) and Nursing Home (65 beds) complex, guaranteed salary if desired, clinic, ancillary services and other fringe benefits will make this difficult to turn down if interested in working in a progressive rural community only 40 miles from a metropolitan area. Smithville Hospital Authority; Irvin Row, Administrator, Box 89, Smithville, Texas 78957. AC 512, 237-2441.

3 EMERGENCY ROOM Physicians wanted to staff new E.R. facilities of 200 Bed Hospital. 50 man multispecialty Clinic physically adjacent provides immediate consultation and support. No pediatric responsibility. Michigan Resort City on Lake Michigan. Salary negotiable. Many fringe benefits. Reply to: John Rasmussen, Administrator, Burns Clinic Medical Center, P.C., Petoskey, Michigan 49770.

PHYSICIAN NEEDED—Orthopedic and General Surgeons, Urologists, Internists, OB—Gynecologists, and General Practitioners to establish independent practice in Petoskey, Michigan.—The Midwest's Skiing Mecca and world famous summer resort community. Local college, excellent schools, seasonal sports, summer and winter concerts. A great selection of restaurants, theatre, hunting, fishing, golfing, sailing, unique and unusual summer shops, and frequent airline service make this an unrivaled living area. New acute care general hospital will provide one year's rental on adjacent luxurious office suites, moving stipened, and negotiate other financial arrangements. Contact—Milton R. Rasmussen, Administrator or Wendell C. Trent, Asst. Administrator, Area 616-347-3985.

GENERAL PRACTITIONER wanted to join one man clinic. Excellent location. No investment. Early partnership. Laboratory and Xray in office. New local hospital. M. R. Williams, M.D., Box 98, Cannon Falls, Minn. 55009. Tel. 507-263-2511.

SEVEN MAN GROUP badly in need of a general surgeon, certified or board eligible. Prefer subspecialty thoracic and vascular, not mandatory. Excellent clinic facilities. Located in a city of 80,000 in Northeastern Iowa with university in metropolitan area. Salary negotiable, partnership at the end of second year. Contact Dr. Richard D. Waldorf or Mr. G. W. Glenn, Business Manager, Waterloo Surgical and Medical Group. 319-234-1541.

HURRY—Our Wilderness Season extended for 1972. So we can book additional elk and deer hunters. Sept. 15-Nov. 29. Call or write today. John W. McMahon, M.D. 2225 11th Ave., Suite 22, Helena, Mt. 59601. 406-442-0671.

GIERE CLINIC FOR SALE—Established 1921. New offices. All walls panelled. All rooms carpeted. Reception room for 16 patients. Private and examing room for two doctors. Rooms—Receptionist. Therapy. Laboratory. Minor Surgery. Storage. Equipment and files included. Efficient technician and receptionist. Two entrances. One for patients and one for doctors. First floor. Air-conditioned. Good parking. Present rent $4 per sq. ft. Address 104 Wesley Temple Bldg., 123 E. Grant St., Mpls., Mn. 55403. Next to Minneapolis Auditorium. Call Dr. J. C. Giere—Home 929-9089. Office 335-7671.

ORTHOPEDIC SURGEON, certified or board eligible to join a seven man group in Northeastern Iowa. Excellent clinic facilities complete with Xray suites, physical therapy department, and laboratory department. Good hospital facilities available in the area. This is an excellent opportunity for the right man. Partnership after the second year. Contact Mr. George W. Glenn, Business Manager, Waterloo Surgical and Medical Group—319-234-1541.

ESTABLISHED—General Practice for sale. Excellent medical and business equipment. Rent new ground floor office space. Open staff hospital. Will sell all or part of equipment. Leaving for institutional work. Write or call: W. B. Halme, M.D., 407 7th St. SW, Wadena, Minnesota. 218-631-2252.

PRISON PHYSICIAN 17—To fill immediate vacancies. Salary range $26,370 to 32,280 annually. All Michigan civil service benefits. Must possess a license to practice medicine or osteopathic medicine and surgery in Michigan, plus five years of such experience. Send resume to Mr. Richard D. Crable, Chief Recruitment and Placement, Michigan Department of Civil Service, Lansing, Michigan 48913. (Minm) An equal opportunity employer.

GENERAL PRACTITIONERS WANTED—Positions available for 2 Generalists to join well established 5 man group in Northern Minn. resort area. Active association with Dept. of Family Practice at U. of Minn. New Clinic building. Modern 50 bed hospital 5 blocks from Clinic; well staffed new 5 bed ICU. Liberal education and vacation benefits, partnership available after 1 year. 200 nearby lakes, excellent fishing, deer hunting; winter skiing, superb snowmobiling. 18 hole golf course and archery range. Good school system. Phone 218-732-3325 or 218-732 4670. Park Rapids Clinic, Park Rapids, MN 56470.

FOR SALE—Doctor's examining table, surgical instruments, gause and plastic bandages and syringes. Phone: 824-2828-Minneapolis.

INTERNIST with subspecialty—10 years solo—wishes to be much busier—will buy practice, form group, join existing group—Minneapolis area. Write: MINNESOTA MEDICINE-471, 375 Jackson St., St. Paul 55101.

Meeting

The District Six Meeting of the American Medical Society on Alcoholism will be held at the Kahler Hotel in Rochester, Minnesota from 2 to 4 p.m. on November 27, 1972.

The meeting will be in conjunction with the Minnesota School on Alcohol and Drug Problems.

The papers that will be presented at this meeting are as follows:

Paper I—Dr. Jose Pozeulo, Mayo Clinic
Title—Supression of Craving and Other Signs of Morphine Dependence in Addicted Monkies by Using AMPT.

Paper II—Dr. Richard Heilman, Veterans Administration Hospital, Minneapolis, Minnesota
Title—Experience in the Treatment of Vietnam Veterans.

Paper III—Dr. Robert Morse and Dr. W. M. Swenson, Mayo Clinic
Title—Experience With an Alcoholism Screening Test on an Alcoholism Treatment Unit.

OCTOBER, 1972

Mayo Medical School Special Issue

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment with, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

To help you manage excessive psychic tension

99% allergen-free air is here

If you wrote a prescription for 100% allergen-free air, we'd come within 1% of filling it. We're the ultra-clean air people. We're Dexon, Inc. — makers of Prime-Aire® Purifiers.*

Man's most efficient air filtering method

Heart of the Dexon Prime-Aire is a HEPA (High Efficiency Particulate Air) filter six inches thick. This is the absolute filter. The most efficient ever developed. It's structured from a dense, sophisticated glass fiber media developed originally for the Atomic Energy Commission to remove airborne radioactive contaminants.

Effectiveness

Prime-Aire's HEPA filter has an efficiency of 99 percent in removing particles 0.5 micron (one micron equals 1/25,000 of an inch) and larger. This includes bacteria, smoke, and fumes. It has even greater efficiency for larger particles, removing essentially 100% of such airborne allergens as dust, pollen, molds and yeast cells.

Operating mode

Prime-Aire's two-speed blower system draws in ambient air through the Dexon-designed pre-filter. This removes large airborne contaminants. Virtually all remaining airborne microorganisms are trapped in the HEPA filter's convoluted folds. Air flowing from the front of the unit is now in excess of 99% allergen-free. A controlled air velocity of 100 feet per minute assures quiet, draft-free operation.

Choice of Units

Two portable models are available. The illustrated Prime-Aire console model purifies the air in an average 1200 square foot home at least once an hour. This model is 18″ x 18″ x 22″ high and weighs 35 lbs.

Our table model (not shown) filters the air in a 12′ x 12′ room five times an hour. It is 18″ wide by 14″ deep by 9″ high, and weighs only 18 lbs. Both models are UL listed.

Easy care

The HEPA filter needs no washing. It's replaced about once a year if used continually. And less often if used seasonally. The pre-filter is replaced monthly during continuous use.

Ordinary purifiers can't compare

Prime-Aire must not be confused with electrostatic devices. The Dexon HEPA filter never needs cleaning. Electrostatic filters require frequent removal and washing. Prime-Aire's filtering efficiency is rated at 99% and beyond. Average reported efficiency of electrostatic devices is 85%. Prime-Aire provides whisper-quiet operation. There's no arcing, snapping or ozone gas as generated by electrostatic methods.

Dexon's history of contamination control

Purifying air is nothing new to Dexon. Nor is it a sideline with us. We've been at it for nearly 12 years. Dexon ultra-clean air work stations are on the job in hospitals. Also pharmaceutical labs, food processing plants, microelectronic component firms and wherever contamination-free air zones are required. There's a reason: Dexon systems consistently meet or exceed Class 100 conditions of Federal Standard 209a for clean room and work station requirements.

Allergy sufferers breathe something rare

With Prime-Aire, many allergy patients have a proven weapon to fight — and often prevent — their suffering and discomfort. When breathing Dexon's ultra-clean air, many of these people report a degree of relief they never before thought possible.

An aid in many places

In promoting a healthful environment, Prime-Aire has uses that go beyond the home. It's also ideal for doctor's offices, consulting rooms, nursing homes — to name just a few places.

Medical data

General Information

Authors: Send manuscripts, subscriptions and communications for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minn. 55101. Telephone (612) 222-6366.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE.

Readers and Reviewers: The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers: Display advertising rates on request. Classified advertising rates appear on classified page.

Annual Subscription—$10.00. Single copies—$1.00. Foreign and Canadian—$12.00.

Copyright and Post Office Entry

Copies of this issue of MINNESOTA MEDICINE copyrighted by the Minnesota State Medical Association © 1972. Published on the first of each month. Permission is hereby granted to reproduce any of the editorial material in this magazine contingent upon customary recognition to MINNESOTA MEDICINE.

Second class postage paid at St. Paul, Minnesota and additional mailing offices. POSTMASTER: Send P.O. Form 3579 to: Minnesota Medicine 375 Jackson St. St. Paul, Mn. 55101.

rheumatoid arthritic blowup...

Tandearil® Geigy

oxyphenbutazone NF

tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, adding those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Patients should discontinue the drug and report immediately any sign of: fever, sore throat, oral lesions (symptoms of blood dyscrasia); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.

Contraindications: Children 14 years or less; senile patients; history or symptoms of G.I. inflammation or ulceration including severe, recurrent or persistent dyspepsia; history or presence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypertension; thyroid disease; systemic edema; stomatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent chemotherapeutic agents, or long-term anticoagulant therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh initially unpredictable benefits against potential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angiitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

a new outlook in chronic pain

of moderate to severe intensity

Though Talwin® Tablets, brand of pentazocine (as hydrochloride), can be compared to codeine in analgesic efficacy, Talwin is not subject to narcotic controls. Patients receiving Talwin Tablets for prolonged periods face fewer of the consequences you've come to expect with meperidine or codeine. And that, in the long run, can mean a better outlook for your chronic-pain patient.

Talwin Tablets are:

- **Comparable to codeine in analgesic efficacy:** one 50 mg. Talwin Tablet appears equivalent in analgesic effect to 60 mg. (1 gr.) of codeine. Onset of significant analgesia usually occurs within 15 to 30 minutes. Analgesia is usually maintained for 3 hours or longer.
- **Tolerance not a problem:** tolerance to the analgesic effect of Talwin Tablets has not been reported, and no significant changes in clinical laboratory parameters attributable to the drug have been reported.
- **Dependence rarely a problem:** during three years of wide clinical use, only a few cases of dependence have been reported. In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.
- **Not subject to narcotic controls:** convenient to prescribe – day or night – even by phone.
- **Generally well tolerated by most patients:** infrequently cause decrease in blood pressure or tachycardia; rarely cause respiratory depression or urinary retention; seldom cause diarrhea or constipation. If dizziness, lightheadedness, nausea or vomiting are encountered, these effects tend to be self-limiting and to decrease after the first few doses. (See last page of this advertisement for a complete discussion of adverse reactions and a brief discussion of other Prescribing Information.)

50 mg. Tablets

Talwin®

brand of

pentazocine (as hydrochloride)

the long-range analgesic

a new outlook in chronic pain

of moderate to severe intensity

Contraindications: Talwin, brand of pentazocine (as hydrochloride), should not be administered to patients who are hypersensitive to it.

Warnings: *Head Injury and Increased Intracranial Pressure.* The respiratory depressant effects of Talwin and its potential for elevating cerebrospinal fluid pressure may be markedly exaggerated in the presence of head injury, other intracranial lesions, or a preexisting increase in intracranial pressure. Furthermore, Talwin can produce effects which may obscure the clinical course of patients with head injuries. In such patients, Talwin must be used with extreme caution and only if its use is deemed essential.

Usage in Pregnancy. Safe use of Talwin during pregnancy (other than labor) has not been established. Animal reproduction studies have not demonstrated teratogenic or embryotoxic effects. However, Talwin should be administered to pregnant patients (other than labor) only when, in the judgment of the physician, the potential benefits outweigh the possible hazards. Patients receiving Talwin during labor have experienced no adverse effects other than those that occur with commonly used analgesics. Talwin should be used with caution in women delivering premature infants.

Drug Dependence. There have been instances of psychological and physical dependence on parenteral Talwin in patients with a history of drug abuse and, rarely, in patients without such a history. Abrupt discontinuance following the extended use of parenteral Talwin has resulted in withdrawal symptoms. There have been a few reports of dependence and of withdrawal symptoms with orally administered Talwin. Patients with a history of drug dependence should be under close supervision while receiving Talwin orally.

In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.

Acute CNS Manifestations. Patients receiving therapeutic doses of Talwin have experienced, in rare instances, hallucinations (usually visual), disorientation, and confusion which have cleared spontaneously within a period of hours. The mechanism of this reaction is not known. Such patients should be very closely observed and vital signs checked. If the drug is reinstituted it should be done with caution since the acute CNS manifestations may recur.

Usage in Children. Because clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Ambulatory Patients. Since sedation, dizziness, and occasional euphoria have been noted, ambulatory patients should be warned not to operate machinery, drive cars, or unnecessarily expose themselves to hazards.

Precautions: *Certain Respiratory Conditions.* Although respiratory depression has rarely been reported after oral administration of Talwin, the drug should be administered with caution to patients with respiratory depression from any cause, severe bronchial asthma and other obstructive respiratory conditions, or cyanosis.

Impaired Renal or Hepatic Function. Decreased metabolism of the drug by the liver in extensive liver disease may predispose to accentuation of side effects. Although laboratory tests have not indicated that Talwin causes or increases renal or hepatic impairment, the drug should be administered with caution to patients with such impairment.

Myocardial Infarction. As with all drugs, Talwin should be used with caution in patients with myocardial infarction who have nausea or vomiting.

Biliary Surgery. Until further experience is gained with the effects of Talwin on the sphincter of Oddi, the drug should be used with caution in patients about to undergo surgery of the biliary tract.

Patients Receiving Narcotics. Talwin is a mild narcotic antagonist. Some patients previously receiving narcotics have experienced withdrawal symptoms after receiving Talwin.

CNS Effect. Caution should be used when Talwin is administered to patients prone to seizures; seizures have occurred in a few patients in association with the use of Talwin although no causal effect relationship has been established.

Adverse Reactions: Reactions reported after oral administration of Talwin include *gastrointestinal:* nausea, vomiting; infrequently constipation; and rarely abdominal distress, anorexia, diarrhea. *CNS effects:* dizziness, lightheadedness, sedation, euphoria, headache; infrequently weakness, disturbed dreams, insomnia, syncope, visual blurring and focusing difficulty, hallucinations (see *CNS Manifestations* under WARNINGS); and rarely tremor, irritability, excitement, tinnitus. *Autonomic:* sweating; infrequently flushing; and rarely chills. *Allergic:* infrequently rash; and rarely urticaria, edema of the face. *Cardiovascular:* infrequently decrease in blood pressure, tachycardia. *Other:* rarely respiratory depression, urinary retention.

Dosage and Administration: *Adults.* The usual initial adult dose is 1 tablet (50 mg.) every three or four hours. This may be increased to 2 tablets (100 mg.) when needed. Total daily dosage should not exceed 600 mg.

When antiinflammatory or antipyretic effects are desired in addition to analgesia, aspirin can be administered concomitantly with Talwin.

Children Under 12 Years of Age. Since clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Duration of Therapy. Patients with chronic pain who have received Talwin orally for prolonged periods have not experienced withdrawal symptoms even when administration was abruptly discontinued (see WARNINGS). No tolerance to the analgesic effect has been observed. Laboratory tests of blood and urine and of liver and kidney function have revealed no significant abnormalities after prolonged administration of Talwin.

Overdosage: *Manifestations.* Clinical experience with Talwin overdosage has been insufficient to define the signs of this condition. *Treatment.* Oxygen, intravenous fluids, vasopressors, and other supportive measures should be employed as indicated. Assisted or controlled ventilation should also be considered. Although nalorphine and levallorphan are *not* effective antidotes for respiratory depression due to overdosage or unusual sensitivity to Talwin, parenteral naloxone (Narcan®, available through Endo Laboratories) is a specific and effective antagonist. If naloxone is not available, parenteral administration of the analeptic, methylphenidate (Ritalin), may be of value if respiratory depression occurs.

Talwin is not subject to narcotic controls.

How Supplied: Tablets, peach color, scored. Each tablet contains Talwin (brand of pentazocine) as hydrochloride equivalent to 50 mg. base. Bottles of 100.

Winthrop Winthrop Laboratories, New York, N. Y. 10016 (15

President's Letter

Growth

To be aware of Minnesota's changing health profession education is exciting and awesome. It reflects the increasing awareness on the part of medicine and lay groups, that cooperative endeavor is needed to solve our health care problems.

To become a physician one must learn to solve a problem by diagnosis, prognosis and then management. In Minnesota today medical educators, physicians, legislators, governing boards of educational and health institutions are struggling to learn these same skills and mastering them with evident progress and further plans to improve health care for our State and its neighbors. The development of the University of Minnesota Health Sciences as an integral unit is one example. The new University curricula and the establishment of the Duluth Branch School of Medicine are other examples. This issue of Minnesota Medicine is dedicated to the new Mayo School of Medicine and it's first class of 40 students. That event is the result of arduous labor by many dedicated people. Dr. Emmerson Ward, Chairman of the Mayo Board of Governors, Dr. Raymond Pruitt, Dean of the Mayo Medical School, and their staffs, as well as the Mayo Foundation, deserve not only our congratulations but active support.

There has never been a time when the practicing physician and the health educator are as important to each other. From acceptance to medical school 'til cessation of all medical activity, each physician is student, practitioner, teacher. To disavow part of this continuum jeopardizes our ability to diagnose, prognose, and manage an individual's health problems or society's health problems.

I am confident that Minnesota physicians join with me in applause for what is being done and active support for continuing exploration of what is yet to be done.

George B. Grantin

President
Minnesota State Medical Association

Not too little, not too much... but just right!

"Just right" amounts of Ilosone Liquid 250 can be dispensed easily from the pint bottle in *any* quantity you specify to meet your patients' precise needs—without regard to package size.

Pulmonary Vasculitides

Importance of the Clinical and Pathologic Differentiation

RICHARD A. ARMS, M.D., DAVID E. DINES, M.D. AND RICHARD A. DeREMEE, M.D.

Several classifications of the vasculitides have been described in the literature.[1-3] Some authors[4,5] have postulated that the necrotizing vasculitides represent a continuum of tissue changes ranging from pure necrosis and granuloma formation to pure angiitis. The diseases that should be considered as pulmonary vasculitides include Churg-Strauss vasculitis, periarteritis nodosa, allergic angiitis, Wegener's granulomatosis, and the pulmonary infiltration with eosinophilia (P.I.E.) syndromes. The pulmonary vasculitides have been classified pathologically by Alarcón-Segovia and Brown.[6] The clinical classification that we have found workable is shown in the Table.*

Goodpasture's syndrome (lung purpura and nephritis) is a pulmonary-renal syndrome usually occurring in young males, commonly with a fulminating and fatal outcome.[7] Recent evidence has suggested that an auto-immune mechanism is operative,[8] but Goodpasture's syndrome and idiopathic pulmonary hemosiderosis are not included in a classification of pulmonary vasculitis because, pathologically, they do not show true vasculitis.[9]

By considering both the clinical and the pathologic features, one can usually make an accurate diagnosis. However, the vasculitides should be differentiated among themselves because the prognosis is different for each and because corticosteroids and immunosuppressive agents may be of value for the treatment of some.

Churg-Strauss Vasculitis

Churg-Strauss vasculitis, also called angiitis granulomatosis, was first described in a retrospective study in 1951.[10] All 13 patients in the study had a syndrome characterized by asthma, marked eosinophilia (eosinophils as high as 84%), and extravascular granuloma formation. Eleven of the 13 patients had died at the time of the study, the chief cause of death being heart failure secondary to myocardial damage and intracerebral bleeding. Typically, the asthma abated and often completely disappeared during the course of the terminal illness. Asthma preceded the terminal illness by an average of three years. Pulmonary involvement resembling Loeffler's pneumonia was noted on the chest roentgenograms in about 70% of patients.

Multisystem disease similar to periarteritis nodosa is characteristic of Churg-Strauss vasculitis and, on pathologic examination, nodular swellings along the course of small arteries can be seen grossly. All stages of necrotizing arteritis with invasion predominantly by eosinophils are usually found. The main difference from periarteritis the presence of the characteristic extravascular granulomatous nodules. Similar nodules have been observed in the lungs of patients with Loeffler's syndrome and Wegener's granulomatosis. In Churg-Strauss vasculitis, these lesions are seen in the lung parenchyma of half of the patients, and in the pulmonary arteries of about 70%.

Since the original description of this entity, very few cases have been published. Inclusion of this disease in other categories of vasculitis partially accounts for its apparent low incidence. A recent case of Churg-Strauss vasculitis is herein presented to describe the clinical and histologic factors that help differentiate it from the other pulmonary vasculitides.

Case Report

A 55-year-old man was seen initially at the Mayo Clinic in 1967 for evaluation of bronchial asthma. He had a three-year history of symptoms compatible with typical nonseasonal asthma of progressing severity. Of significance was a past history of vasomotor rhinitis, nasal polyps, and multiple allergies.

Physical examination revealed no abnormalities except for inspiratory and expiratory wheezing and a prolonged expiratory phase. The chest roentgenogram was normal. Pulmonary function studies showed airway obstruction

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

*See page 874.

with good reversibility after the use of nebulized isoproterenol. Results of all other laboratory studies were normal except for 8% eosinophils. The patient was instructed to reduce the dose of cortisone that he had been taking and to continue with hyposensitization and various bronchodilators.

The patient returned in November 1971 for re-evaluation. He had had no further bronchospasm since the previous summer. However, a spasmodic cough with occasional hemoptysis had developed. During this time, he also had developed recurrent asymptomatic skin lesions resembling "blisters"; these were especially severe on the tongue, lips, and hands. Physical examination showed a small ulcerating lesion of the hard palate and vesicular lesions of the hands and arms. The lungs were clear and were without evidence of bronchospasm. Laboratory studies included a leukocyte count of 34,600/cu mm. with 85.5% eosinophils. Urinalysis showed hematuria of grade 2; creatinine clearance was 80 ml/min. The chest roentgenogram revealed an ill-defined density in the left lower lobe. Results of pulmonary function tests were essentially normal, with only a slight decrease in the maximal midexpiratory flow rate. Bone marrow examination indicated severe marrow eosinophilia. Biopsy of one of the skin lesions revealed fibrinoid necrosis of vessel walls and an extravascular granulomatous reaction compatible with Churg-Strauss vasculitis.

Periarteritis Nodosa

Periarteritis nodosa was originally described in 1866 by Kussmaul and Maier,[11] and was considered to be rare until 1923, when Ophuls[12] described the second case—one with pulmonary artery involvement. He enumerated nine features that differed from the original description; and after his publication, the term "periarteritis nodosa" included many vasculitides, making the incidence of pulmonary involvement with this entity difficult to ascertain. Rose and Spencer[13] reviewed 111 cases of periarteritis nodosa and found that 28% of the patients had pulmonary involvement; however, some of these may have had Wegener's granulomatosis, Churg-Strauss vasculitis, or allergic angiitis because the pulmonary vasculitides were not as well defined in 1957. The incidence of pulmonary involvement in pure periarteritis nodosa is probably less than 10%.

Periarteritis nodosa can occur at any age and affects males more often than females. It frequently presents as a multisystem disease, although selective involvement such as mononeuritis multiplex may be the only presenting feature. Typically, the disease has an intermittent course and is uniformly fatal in a few months to several years. Renal involvement is the most striking abnormality. In 52 of 66 patients studied by Rose and Spencer,[13] hematuria and early renal failure occurred. Hypertension often occurs late in t disease. The pulmonary involvement that is se probably occurs more frequently in the bronch arteries. The findings on the chest roentgenogra are nonspecific and consist primarily of patc parenchymal infiltration; pleural and pericard effusion as well as infarction with cavitation c be seen occasionally.

On pathologic examination, the lesions a often visible grossly and occur in small a medium-sized muscular arteries, particularly their bifurcations. Microscopically, focal lesio in several stages of development are characterist the initial manifestation being fibrinoid necro with infiltration of polymorphonuclear leukocyt Eosinophilia is not necessary for the diagnos and giant cells and granulomas are usually n seen.

Allergic Angiitis

Allergic angiitis is typically an acute vascul reaction largely attributed to exposure to scru or drugs, resembling the Arthus type of reaction Clinically, either the course is fulminating and u remitting or the patient recovers without recu rence once the offending agent has been remove Cutaneous involvement is prominent and syn metric, particularly in the dependent portions the body. The lungs are frequently affected, a the chest roentgenogram may show nonspecif features similar to those seen in periarteriti Chronic renal disease, hypertension, and peripl eral neuropathy are usually not part of the fin ings of allergic angiitis.

Pathologically, only small arteries and veins a affected. In contrast to periarteritis nodosa, a lesions appear to be at the same stage of inflan mation; there is no predilection for bifurcations aneurysmal formation. The vessels show an i tense cellular response, with prominence of eosin phils.

Wegener's Granulomatosis

Three related entities can be categorized Wegener's granulomatosis: (1) Wegener's granul matosis with renal disease, (2) limited Wegener granulomatosis and (3) midline granuloma.

Wegener's granulomatosis is classically con posed of the triad of necrotizing granulomas the upper respiratory tract, disseminated angiiti and focal glomerulitis. In most series, two thir of the patients have destructive granulomas of th upper respiratory tract, and an even greater pe

ntage have pulmonary infiltration. Clinically, e disease is characterized by a severe and pro- essive sinusitis, cough, and finally, in most ses, renal failure.[15,16] On microscopic examina- n,[17] arteritis and phlebitis are generally separate m the areas of necrosis. This can be difficult prove, however, because necrosis may destroy e evidence of vasculitis. Treatment of Wegen- 's granulomatosis with immunosuppressive ugs (azathioprine, 150 mg/24 hr, or chloram- cil, 2.0 mg/24 hr) has brought about a 1-year rvival rate of 80% as compared to 34% with roids and 18% for patients who are not treat- l.[18] In one series, cyclophosphamide, in a dose 50 to 125 mg/24 hr, has resulted in a partial or mplete remission in seven of nine patients with Vegener's granulomatosis.[19]

Lethal midline granuloma is an invariably fatal lness characterized by progressive destruction of e facial structures by an inflammatory process. lthough granulomatosis accompanies the necro- s, true vasculitis does not occur. This entity, owever, should be included within the classifica- on of disorders under discussion.

Recently, a limited form of Wegener's granu- matosis has been described in which only the ungs apparently are involved. Carrington and Liebow[20] have described 16 patients who had the linical features and pulmonary lesions identical o those of Wegener's granulomatosis, but without he characteristic renal involvement. The chest oentgenogram in the limited form shows multiple, ilateral, frequently cavitating, thin-walled lesions rimarily in the lower lung fields,[21] which clini- ally may simulate neoplasm or infectious caseous granuloma. For the diagnosis of limited Wegener's granulomatosis, there must be microscopic evi- dence of vasculitis and separate necrotizing granulomas in the pulmonary biopsy specimen. There is no specific pattern of response to therapy, but there may be longer survival in the limited form.

Case Report

A 74-year-old white woman presented with the chief complaint of shortness of breath. Approximately four months before admission, she noted a gradual onset of dyspnea on exertion and easy fatigability. This was subsequently accompanied by a loss of 18 pounds in spite of a good appetite and apparently adequate food intake. She was hospitalized, where she was treated for congestive heart failure and depression with digitalis and Triavil, a tranquilizer-antidepressant, with little or no change in her status. Shortly before referral to the Mayo Clinic, a chest roentgenogram revealed multiple bilateral ill-defined nodular lesions suggestive of metastatic carcinoma.

On physical examination, the temperature and pulse were normal. The blood pressure was 170/106 mm Hg. She appeared pale and chronically ill. A few scattered nonspecific basilar rales were heard on auscultation of the chest. There was a grade 2/6 ejection systolic murmur heard best in the aortic area and transmitted along the left sternal border. There were no gallops and the jugular venous pressure was normal.

Results of urinalysis and routine blood counts were normal. The serum creatinine level was 0.85 mg/100 ml, and the 12-hour creatinine clearance was 78 mm/min/1.73 sq m. An induced sputum for malignant cells was negative. Sputum cultures and serologic tests for fungi also were negative.

A chest roentgenogram four weeks later showed that some areas had improved and others had worsened. Because of this changed pattern, the diagnosis of vasculitis was considered and open-lung biopsy was undertaken. The open-lung biopsy revealed a necrotizing granulomatous lesion consistent with the localized form of Wegener's granulomatosis.

Therapy with cyclophosphamide, 50 mg twice a day, was started. Approximately two weeks after therapy was begun, the patient noted an increased sense of well-being and a chest roentgenogram revealed improvement.

Pulmonary Infiltration with Eosinophilia Syndromes (P.I.E.)

Loeffler's syndrome[22,23] is a typically benign condition characterized by eosinophilia and migrating lung infiltrates that may be unilateral or bilateral and located in any part of the lung. Clincially, the symptoms may include mild to high fever, severe bronchospasm, and shortness of breath. The percentage of eosinophils in the blood may range from 10% to 80%. In only a few cases of Loeffler's syndrome has biopsy been done; the usual finding is interstitial and alveolar edema with eosinophil infiltration.

Carrington and co-workers[24] have described nine patients with chronic eosinophilic pneumonitis who had a chronic life-threatening illness with high fever, night sweats, loss of weight, and severe dyspnea. Most patients had tuberculosis as the initial diagnosis. Six patients had asthma. The roentgenogram of the chest showed characteristic rapidly progressive dense infiltrates. Lung biopsies showed chronic interstitial pneumonitis with fibrosis. Corticosteroid therapy resulted in complete clinical recovery and roentgenographic clearing in five days.

Because Loeffler's pneumonia has terminated in fatal periarteritis nodosa,[25] Loeffler's syndrome

and chronic eosinophilic pneumonitis must not be considered invariably benign disorders but rather a spectrum of a disorder in the vasculitides classification.

In Loeffler's syndrome, treatment can be based on the acuteness and severity of the illness; not all patients with Loeffler's syndrome need to be treated. The acutely ill patient with Loeffler's syndrome and the patient with chronic eosinophilic pneumonitis presenting with fever, loss of weight, night sweats, and dyspnea should be treated with corticosteroids—prednisone, 40 mg/day or 60 mg every other day. The dose should be tapered to a maintenance dose or be discontinued, depending on the clinical response. All patients with positive tuberculin test reactions should be treated prophylactically with isoniazid, 300 mg/day, while on the corticosteroid regimen.

TABLE
Clinical Classification of the Pulmonary Vasculitide

- **Churg-Strauss vasculitis**
- **Periarteritis nodosa**
- **Allergic angiitis**
- **Wegener's granulomatosis**
  - **Wegener's granulomatosis with renal involvement**
  - **Limited Wegener's granulomatosis**
  - **Midline granuloma**
- **P.I.E. (pulmonary infiltration with eosinophilia) syndromes**
  - **Loeffler's syndrome**
  - **Chronic eosinophilic pneumonitis**

Conclusions

The pulmonary vasculitides include a wi range of disorders. By considering both the clin cal and the pathologic features one can usual make the diagnosis. The disorders must be di tinguished among themselves because the progn sis is different and because corticosteroids an immunosuppressive agents may be of value i the treatment.

Surgical Treatment of Thyroid Nodules

OLIVER H. BEAHRS, M.D. AND CLARENCE R. PETRIE, M.B., Ch.B.

Nodular goiter occurs frequently and is cognized in possibly as high as 50% of the ases. In a recent study of approximately 150,000 atients at the Mayo Clinic (200,000 effective egistrations), 3,000 patients were seen who were oted to have significant goiters of various types. ome patients were observed only; some received edical treatment (radioactive iodine, usually for xophthalmic goiter, thyroid replacement therapy or Hashimoto's thyroiditis, and symptomatic reatment for subacute thyroiditis), and the remainder were treated surgically. Thyroidectomy vas performed on 365 patients. Of the operations erformed, 347 were for nodular goiter: 14 for yperthyroidism, 18 for known cancer, and the thers for factors leading to an increased suspicion f cancer (or for other symptoms). Fifteen per- ent of the nodular goiters proved to be carcinoma.

It is neither practical nor feasible to resect all linically apparent nodular goiters. Selection for hyroidectomy must be made on the basis of the istory, the physical findings, and the laboratory nformation. Also the decision is based on the udgment of the physician regarding significant risk to the patient if the goiter is left untreated as opposed to the risk, inconvenience, and cost of removal. Indications for removal include the objectionable cosmetic appearance of obvious goiters, pressure symptoms or compression of other anatomic structures of the neck (trachea and esophagus) and thoracic inlet (including major vessels), hyperthyroidism or the risk of its development if the goiter is of considerable bulk (possibly 10% or more of nodular goiters), and, lastly, known or suspected underlying cancer. The decision to remove a nodular goiter for cosmetic appearance or pressure symptoms is easily reached. If there is no contraindication to surgery (cardiac, pulmonary, or other significant disease), thyroidectomy is the most immediately effective treatment for an adenomatous goiter with hyperthyroidism. The decision as to treatment of nodular goiters that are obviously cancerous is not difficult. Controversy and difference in selection of treatment result when a nodular goiter is present, when it is not suspected of being a cancer, and when the patient is asymptomatic. The decision is complicated further by the fact that there are some investigators who think that cancer of the thyroid gland either does not exist or is of such a "benign" nature that it does not require treatment; there are others who think that cancer of the thyroid should always be treated radically. Treatment lies between these extremes and the differing biological behavior of thyroid cancers must be recognized. At one extreme is the papillary adenocarcinoma, which is slow growing with the patient living many years before the lesion causes symptoms or death; at the other extreme is the anaplastic cancer, which grows rapidly and kills in a matter of months.

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

Contributing Factors

Brief comments follow on the many factors that contribute to the judgment to remove a nodular goiter.

Age of Patient

The risk of cancer in a nodular goiter in a child is approximately 50%. In the adult, probably an incidence of 5 to 10% in surgically removed goiters is reasonable to expect. Our previously reported figures were 7.5% in all nodular goiters and 3.8% in asymptomatic nodular goiters not suspected of being cancer. More recently, the overall figure has been 12 to 14%.

Sex

Goiters are more frequent in women than in men. However, the incidence of cancer in nodular goiter is greater in men. On this basis, a man with a nodule in the thyroid gland is more often a candidate for thyroidectomy than is the opposite sex.

History

If a goiter has been present for many years without significant change in size, the risk of cancer is less than if the lesion is new or has recently shown an increase in size. Sudden enlargement and pain in a nodule are likely indications of hemorrhage into a pre-existing adenoma. Cancers are rarely painful. History of radiation exposure to the neck during childhood is significant in a patient with a recently noticed nodule in the thyroid in that it increases the risk of malignancy. Medullary cancer (Sipple's syndrome) is familial in many cases, and a history of thyroid cancer in family members must be given consideration.

Physical Findings

A discrete solitary lesion is considered more likely to be cancer than a multinodular goiter. "Single" is a term not used to describe nodules of the goiter because often what is considered to be a "single" nodule clinically proves to be a multinodular goiter on surgical removal. In a multinodular goiter, a discrete nodule within it might be a cancer or a cancer might co-exist without being evident on palpation. The consistency of the lesion is important; if it is firm but not hard like calcium, cancer is more likely than if the tumor is soft and cystic. However, a follicular cancer can be relatively soft. If fixation to overlying tissue is evident, cancer should be suspected, but it must be remembered that Riedel's struma and granulomatous thyroiditis might also be somewhat fixed to adjacent tissues. When cervical lymphadenopathy is present the thyroid gland should always be carefully palpated. In our experience 22% of papillary adenocarcinomas of the thyroid are first diagnosed by excision of an abnormal cervical lymph node. Venous congestion of the veins of the neck leads one to suspect pressure within the thoracic inlet, possibly by a goiter projecting into the chest.

Laboratory Findings

Laboratory function tests contribute little to the diagnosis of cancer except for the determination of thyrocalcitonin in suspected medullary adenocarcinoma. Levels above 800 picograms per milliliter (800 pg/ml) are diagnostic of the tumor even though no goiter can be palpated. In questionable hyperthyroidism, the results of thyroxine and radioactive iodine uptake studies are of value. In nodular goiters suspected of being Hashimoto's thyroiditis, thyroxine levels may b normal or high. For granulomatous thyroiditis th sedimentation rate is high (about 100 mm/hr The radioactive iodine scan will determine wheth the nodule takes up little or no iodine (col nodule), in which case cancer is more likely pre ent, or whether it takes up an increased amou (hot nodule), in which cancer is much less likel Findings on scanning are not absolute. In a grou of patients with cancer of the thyroid, 60% ha cold nodules; in 34% the scans were norma and in 6% the area of the nodule or the nodul itself was hot. Therefore, the result of the sca itself must not dictate the management of th goiter. X-ray examination of the chest will aid i determining whether there is deviation or com pression of the trachea and the substernal pres ence of the goiter. Barium swallow will sho displacement of the esophagus. Needle biopsy o the thyroid is not recommended unless Hashi moto's thyroiditis is suspected.

Surgical Experience

The surgical experience of the surgeon or th institution is to be considered in deciding fo elective thyroidectomy. In our experience th mortality rate for thyroidectomy is 0.1% and th morbidity rate is low (permanent tetany 0.3% and unilateral vocal cord paralysis less than 1%) These figures are sufficiently low to justify elec tive surgery. On the other hand, with morbidity rates significantly higher, selection of goiter fo thyroidectomy must be stricter and less frequently recommended.

The extent of surgery is based on the pathologic findings. For a discrete nodule confined to one lobe and proved to be benign on gross inspection and study of frozen sections, partial lobectomy is sufficient on the side of the lesion if the opposite side is normal. For bilateral benign lesions or for thyroiditis, bilateral subtotal resection with removal of the isthmus is indicated, leaving a thyroid remnant of 1 to 2 gm of tissue on each side of the trachea. When papillary adenocarcinoma is found, total lobectomy on the side of the tumor should be done as well as partial lobectomy on the opposite side since 20% of these cancers are multicentric. For extensive papillary lesions (extrathyroidal or multicentric cancer invading both lobes), total thyroidectomy should be considered. About half of these lesions will metastasize to cervical lymph nodes; modified neck dissection should then be done. Radical neck

dissection is indicated only when metastatic nodes are extensive (10% of cases with positive nodes).

For follicular adenocarcinoma, total lobectomy on the side of the lesion is indicated, and if there is evidence of blood vessel invasion or distant metastasis, total thyroidectomy should be done to prepare the patient better for radioactive iodine therapy, if and when it is necessary. Lateral neck surgery is infrequently indicated, since this tumor rarely spreads to the regional lymphatics. Medullary adenocarcinoma is multicentric in origin in a high incidence of cases and is more aggressive as cancer. For these reasons total thyroidectomy should be done. Prognosis for this tumor is related to the presence or absence of regional lymph node metastasis. Therefore, radical neck dissection should be done if nodes are considered positive for metastasis or if the primary lesion is considered aggressive. Anaplastic cancer of the thyroid is best treated aggressively although cure is infrequent. An adequate airway should be established if at all possible.

Summary

Nodular goiter should be selected for thyroidectomy on the basis of many factors, including history, physical findings, laboratory results, and the experience of the surgical practice. With careful selection, approximately 20% of nodular goiters recognized clinically will require surgical treatment. About 10 to 15% of these goiters will prove to be cancer. The extent of the surgical procedure should be tailored to the pathologic findings of the goiter and, in the case of cancer, to the known biological behavior of the particular cell type.

Meeting

Hennepin County Academy of Family Physicians

The Annual Invitational Banquet of the Hennepin County Academy of Family Physicians will be held on Monday evening, November 20, 1972, at the Sheraton Ritz Hotel in downtown Minneapolis. A social hour will begin at 6:00 p.m. with dinner scheduled for 7:30 p.m. The Speaker will be Dr. Murray Banks, Adjunct Professor of Psychology at Northwood Institute, Midland, Michigan. His speech is entitled 'What to Do Until the Psychiatrist Comes!" and you won't want to miss his "witty, wise, rare magic." We invite, and encourage to attend, any physicians and their guests, both from the metropolitan and out-of-state areas, to an enjoyable evening at the Sheraton Ritz. Those wishing information or tickets, please contact Donald L. Wright, M.D., 3620 Central Avenue N.E., Minneapolis, Minnesota 55418, telephone 780-1151.

Dr. Stirling . . . was liked being a man of broad sympathies. In his rich Scotch accent, he could discuss with equal ability the flavour of whisky or of a sermon, and he had more than sufficient tact never to discuss either whiskies or sermons in the wrong place. . . . He listened very seriously to all that [his patients] said; he seemed to regard [every] case as the one case that had ever aroused his genuine professional interest; but as it unfolded itself in all its difficulty and urgency, so he seemed, in his mind, to be discovering wondrous ways of dealing with it; these mysterious discoveries seemed to give him confidence and his confidence was communicated to the patient by means of faint sallies of humour. He was a highly skilled doctor. This fact, however, had no share in his popularity, which was due solely to his rare gift of taking a case very seriously while remaining cheerful.*

Dementia

A Clinical Approach

BURTON A. SANDOK, M.D.

THE PATIENT WITH failing mental function poses for the physician a wide array of diagnostic considerations. If the patient is elderly and his symptoms have progressed slowly, frequently the tendency is to assume that the problem is one of a group of presenile or senile dementias[1] and to limit diagnostic evaluation. There are, however, potentially treatable forms of dementia; and this approach precludes the possibility of restoring mental function in these instances of reversible disease.

Clinical Approach

Seldom do patients with a dementia present complaining of mental change. Other family members note some change in the patient's behavior and persuade him to seek medical aid.

The patient often comes to the physician with somatic problems that poorly fit the more typical patterns of physical disease. In eliciting the history, which at times is vague, unclear, and imprecise, the clinician may suspect mental alteration. He should always try to confirm this impression by consulting other family members.

Faced with such a problem, the physician must plan his evaluation to answer two basic questions: (1) Does the patient have a dementing process? and (2) If so, what is the cause? That is, is it a potentially treatable (arrestable or reversible) form of dementia or one not likely to respond to specific therapy?

Initial Clinical Classification

A useful clinical classification is outlined in Table 1.

Several functional alterations in mental processes may superficially resemble a dementia.[2] Depression is the most frequent in this category because the accompanying mental lethargy and psychomotor retardation are often construed as diminished mental capacity. Patients with focal neurologic disorders, especially those who are unable to cope with their environment owing to faulty processing of language (dominant hemisphere disease) or faulty perceptual orientation (nondominant hemisphere disease), may seem perplexed and confused; the difficulty is often interpreted as a dementing process. Such deficits may be prominent in a diffuse dementia, but when such abnormalities exist in isolation, one must be alert to the possibility of a focal structural lesion.

The patient may notice the subtle changes and failing mental processes associated with an early dementing process and react to these changes in accord with the dictates of his own personality. Although depression is common, other behavioral aberrations may be seen. Though the presenting symptoms seem appropriate to a functional disorder, these may merely be reactions to an organic deficit. The clinician should seek evidence of a dementing process in any patient with recent personality change, regardless of the superficial symptoms.

In some patients dementia is merely one aspect of a more obvious systemic or neurologic disease. In such patients differential diagnosis or management is seldom difficult.

There remains, however, a significant number of patients in whom, after careful clinical examination, no evidence of underlying disease can be

TABLE 1
Dementia: Initial Clinical Classification

Pseudodementia: disorders that may mimic dementia
- **Functional states: depression, dissociative states, anxiety, hysteria, etc.**
- **Focal neurologic disease: specific language deficits (dominant hemisphere disease), disorders of visual-spatial orientation (nondominant hemisphere disease)**

Pseudo-pseudodementia: disorders presenting primarily as functional states, but which are merely a reaction to an underlying organic process

Dementia with obvious associated disease

Dementia without obvious associated disease
- **Potentially treatable disorders**
- **"The rest"**

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
See editorial, page 913.

detected. In most of these patients change is irreversible; and there is a tendency, in the elderly patient, to accept arteriosclerotic cerebrovascular disease as the usual cause. It must be pointed out that current studies suggest that there is no precise relationship between dementia and underlying vascular disease.[3] In some patients the mental change can reflect an underlying, potentially treatable disease, which can benefit from specific therapy. The clinician is obligated to ascertain whether such a disorder is present before committing the patient to live out his years with significant disability.

Clinical Examination

No specific test enables the physician to diagnose a dementia. While talking to the patient he must be able to recognize those features of an organic brain syndrome which seem to be common to all patients with a dementia, regardless of specific cause (Table 2). These symptoms are superimposed upon the patient's previous personality, environmental situation, current emotional stresses, and those symptoms attributable to the specific etiologic agent responsible for the impairment of brain function.[4]

TABLE 2
Dementia: Clinical Features

Common basic features (mnemonic = JOMAC)
- **Impairment of**
  - **Judgment**
  - **Orientation**
  - **Memory**
  - **Affect (and abstraction ability)**
  - **Calculation (and comprehension, concentration, and other intellectual functions)**

Impairment superimposed on symptoms relating to
- **Previous personality**
- **Environmental factors**
- **Current emotional stresses**
- **Specific etiologic agent**

The clinical examination differs little from that required for any patient presenting for a general physical examination. But the ease with which a mildly demented patient can relate the history and appear to be mentally quite intact is deceptive. The defect of mental functioning becomes apparent only when the patient is stressed with the unfamiliar or the uncommon. Therefore the answers to simple questions directed at testing speech and language ability, recent memory, judgment, calculation, orientation, and fund of knowledge are likely to be revealing. A complete general physical examination, including a survey of neurologic functioning, should be made.

Clinical Diagnostic Considerations

Table 3 outlines the management based on diagnosis. For those patients with a dementia, but who also show symptoms and signs of systemic disease (group C), the approach is that of evaluating the underlying disorder. For those with abnormalities in both the neurologic examination and mental function (group D), appropriate neurologic referral seems indicated. If there is no obvious associated disease and there is still a question as to whether a dementing process is present (group B), psychologic testing should be done. If there is no evidence of a dementia (group A), reassurance and understanding are frequently beneficial; however, psychiatric referral is warranted if significant psychopathology is evident.

TABLE 3
Dementia: Diagnostic Conclusions and Approaches to Management

Group	Diagnostic Conclusion	Management Approach
A	No dementia present; functional disorder likely	Reassurance; psychiatric referral if indicated
B	Dementia possibly present	Formal psychologic testing should be obtained to confirm or deny the presence of a dementia
C	Dementia present, but secondary to obvious systemic disease	Evaluation and treatment of the primary disorder
D	Dementia present; possibly secondary to a focal cerebral lesion	Appropriate neurologic evaluation
E	Dementia present; no obvious evidence of underlying systemic or focal neurologic disorder	Obtain screening tests, for occult, but possibly treatable cause Consider further diagnostic study if indicated

The remainder of patients consist of those with an obvious dementia, but in whom there seems to be no significant associated systemic or neurologic disease. Table 4 lists some of those disorders in which dementia may be the initial (or most prominent) manifestation, and in which specific therapy can effect remission of some of the mental symptoms. Review of this listing suggests that most of these diseases can be detected (or at least suspected) by a careful history and clinical examination supplemented by selection of basic laboratory tests aimed at uncovering these disorders.

Roentgenography of the head supplemented by electroencephalography and radioisotope scanning occasionally reveal *focal brain lesions* not evident after neurologic examination. A hematologic survey, tests of metabolic function, and chest Xray should also be obtained.

The association between *thyroid dysfunction*

and mental change is well recognized.[5] Since these mental changes may develop in the absence of other obvious clinical signs of myxedema or thyrotoxicosis, evaluation of thyroid function is important in an unexplained dementia.

TABLE 4

Dementia: Potentially Treatable Causes*

Neoplastic disorders	Brain tumor (frontal lobe, intraventricular, etc.)
Endocrine disorders	Thyroid, parathyroid, and adrenal; dysfunction; hypoglycemia
Other metabolic disorders	Hepatic, renal, pulmonary insufficiency
	Hyponatremia
	Porphyria
	Wilson's disease
Exogenous toxins	Drugs (barbiturates, bromides); heavy metals
Deficiency states	Hypovitaminosis B_{12}
	Wernicke-Korsakoff syndrome
	Pellagra, etc.
Vascular disorders	Post-subarachnoid hemorrhage with hydrocephalus
	Secondary to sustained hypertension
	Systemic lupus erythematosus
Post-traumatic disorders	Subdural hematoma
	Communicating hydrocephalus
Inflammatory disorders	General paresis
	Brain abscess
	Meningoencephalitis, chronic
	Postinflammatory arachnoiditis with hydrocephalus
Miscellaneous conditions	Recurrent seizures
	Hematologic disorders
	Remote effect of carcinoma

*Partial listing only.

Mental change has long been known to be a common accompaniment of *pernicious anemia.*[6] Patients with B_{12} deficiency having dementia but having no other signs of the classic disorder nor evidence of anemia have been reported.[7] Neither the absence of anemia nor obvious morphologic change in the blood smear appears sufficient to rule out this disorder, and specific testing (Schilling test, serum B_{12} assay) seems indicated.

Central nervous system *syphilis,* once a prominent cause of dementia, is still encountered; appropriate serologic testing is mandatory.

Dementia, associated with communicating *hydrocephalus,* is a potentially treatable disorder[8] which may follow conditions such as subarachnoid hemorrhage, trauma, and chronic meningitis or may arise without apparent antecedent cause. The characteristic picture includes dementia, apathy, gait disturbance, and urinary incontinence.[9] The differential diagnosis of this disorder involves other considerations including that of an intracranial space-occupying lesion.

Examination of cerebrospinal fluid may prove necessary; however it should be deferred in most patients with evidence of focal neurologic abnormality for it may interfere with other tests, such as radioactive cisternography and pneumoencephalography.

Conclusions

A patient presenting with symptoms suggestive of a dementia may have one of a variety of disorders. Frequently one is inclined to regard the dysfunction as symptomatic of a group of ill-defined diseases of the senium and presenium and to limit evaluation. There are several not uncommon disorders that may present as a dementia and that may be reversed once appropriate therapy is instituted.

A systematic approach to the investigation of a patient presenting with a dementia enables the clinician to discover potentially reversible causes of dementia and to administer specific therapy.

Injuries of Knee in Athletes

FRANKLIN H. SIM, M.D. AND LEE C. DETENBECK, M.D.

PHYSICIANS ARE TAKING increasing interest in sports medicine. Many are actively engaged in the prevention, diagnosis, and care of injuries of athletes. Because the knee is the joint most easily injured, a sound understanding of its functional anatomy[1] and the associated clinical problems is important.

Stability of the knee depends on static and dynamic elements. The static support includes the medial and lateral collateral ligaments, the posterior capsule with its ligamentous thickenings, and the strong fan-shaped cruciate ligaments. All act synergistically to prevent abnormal lateral, rotatory, and anteroposterior motion. The most important dynamic stabilizer is the powerful quadriceps extensor mechanism. Other dynamic stabilizers are the hamstring muscles, the two heads of the gastrocnemius, and the popliteal muscle. In addition, the medial and lateral menisci and the joint articular surfaces must be intact to allow stable, smooth knee motion.

Proper physical conditioning and muscle strengthening prior to participation in strenuous sports are of paramount importance in preventing injuries. Knee injuries may present to the physician early or late. Diagnosis is much easier if the knee can be examined immediately after injury, before significant pain, spasm, and swelling develop. If the ligaments, menisci, articular cartilage, and quadriceps extensor mechanism are remembered when examining the knee, most traumatic lesions can be diagnosed clinically.

Ligamentous Injuries

The most disabling knee injury is rupture of the medial collateral ligament. The medial ligament consists of a long superficial portion and a shorter deep capsular portion that is attached to the medial meniscus. Brantigan and Voshell,[2,3] and more recently Slocum and Larson,[4] have contributed most to our understanding of this functionally important structure. The latter authors also stressed the importance of the entire medial capsule of the knee, extending from the popliteal space posteriorly to the patellar tendon anteriorly.

The position of the knee at the time of injury determines the anatomic defect. In extension the posteromedial capsule becomes taut and the superficial portion of the tibial collateral ligament moves forward and tightens. With 30° to 60° flexion these structures are relaxed and stress is applied to the taut meniscofemoral and meniscotibial portions of the deep medial capsular ligament. The anterior third of the capsule, which is reinforced by the retinaculum of the vastus medialis, is tightened passively when the knee is flexed. Combined rotatory and abduction stress, when severe, gives rise to concomitant injury to the medial meniscus and anterior cruciate ligament completing O'Donoghue's unhappy triad.

As stated previously, the most important factor is early examination, for it is then that the physician can best determine the integrity of each of these structures in the knee. Determination of the exact sequence of events leading to the injury will give some idea about its severity, especially if the athlete can give an accurate description of how the injury occurred. Most frequently the foot is fixed to the ground. The thigh rotates inward, the foreleg outward, and the knee is forced medially with primary stress on the medial ligaments and capsule. This is commonly caused by the lateral blocking maneuver in football or when a player falls on the outstretched leg. These injuries also may occur in noncontact activities such as running, where the foot is forced into external rotation and stress is exerted against the medial ligament. If an athlete has immediate pain but is not disabled, can bear weight, and walks off the field, the symptoms are suggestive of partial rupture of the ligament. Gradual progression of pain, swelling, and restriction of motion may follow. The sequence of events suggestive of more extensive ligament damage includes inability of the patient to bear weight and the development of early severe pain, swelling, and ecchymoses.

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

Treatment of the ligament injuries depends on the severity.[5] With a mild injury and no loss of ligament strength, prompt resumption of activity may be allowed after the local reaction subsides. If the sprain is of moderate severity, that is, the ligament is partially torn but no lateral instability is noted, treatment includes: compression, ice packs, aspiration and local injection, protection in a cylinder cast, and rehabilitation. In complete ligamentous disruption, lateral instability is evident (Figure 1 A). A palpable defect in the ligament may be present and often a "vacuum sign" or local invagination of the skin which is caused by negative intra-articular pressure as the joint is sprung open. When the integrity of the ligament is in doubt, we do not hesitate to examine it under general anesthesia.

When ligamentous disruption is ascertained, exploration of the knee with repair of the ligaments and excision of a torn meniscus is done to prevent residual instability[6,7] (Figure 1 B). Management of the torn anterior cruciate ligament is more controversial. If it is detached from the tibia or femur, it should be repaired through drill holes in the bone. If it is torn and attenuated in its midportion, repair is difficult and often unrewarding. In these instances, we frequently excise the ligament and repair only the medial collateral ligament. With adequate strengthening of the quadriceps, few patients note any disability but resumption of *strenuous athletics* is often impossible. Primary ligament repair, when feasible, is always preferable.

Rotary instability[8] or abnormal increased outward rotation of the tibia on the femur may be disabling to the athlete. The basic lesion that permits this external rotation of the tibia is injury to the deep medial capsular ligament. Instability in lateral movement is noted especially when cutting away from the supporting foot. In order to control this rotary instability, the muscles of the pes anserinus tendon (sartorius, gracilis, and semitendinosus muscles) are transplanted along the medial aspect of the patellar tendon and medial flare of the tibia, converting these muscles from primary knee flexors to internal rotators of the tibia (Figure 2).

Injuries to the Menisci

The term "internal derangement" describes a

Fig. 2—The inferior two thirds of the pes tendon has been detached, reflected, and re-attached to the tibial tubercle and margin of the tibia.

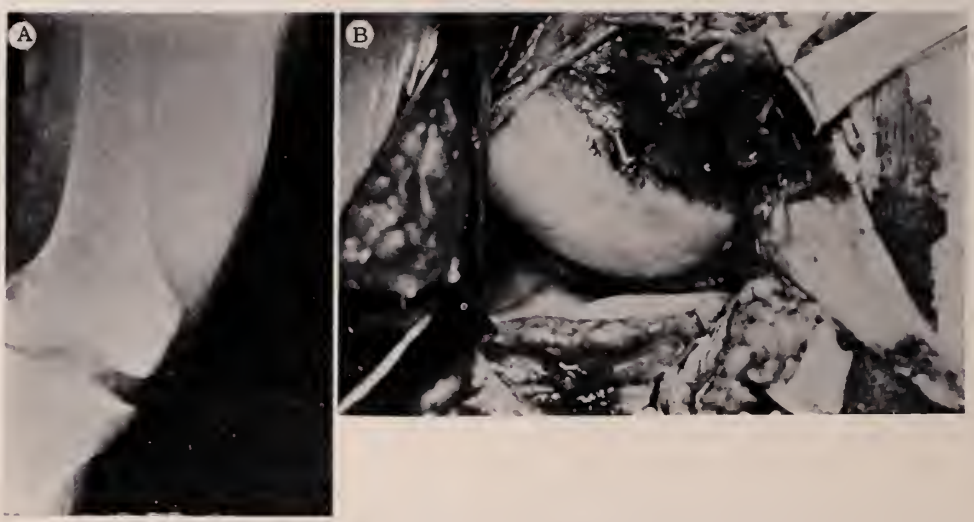

Fig. 1—(*A*) Anteroposterior view of knee under stress showing lateral instability. (*B*) Torn medial collateral ligament showing superficial and deep portion of ligaments torn at joint line and held by retractor. The layers were repaired separately with anatomic approximation.

broad syndrome in which normal motion of the knee is impeded. Injuries of the menisci are common among athletes whose knees are subjected to strong rotational forces, especially when the foot is fixed to the ground and the knee is flexed. A portion of either the medial or lateral meniscus becomes displaced beneath the corresponding femoral condyle; and, as the knee extends, the meniscus is impaled and torn. Clinically, injuries to the meniscus may vary depending on the extent

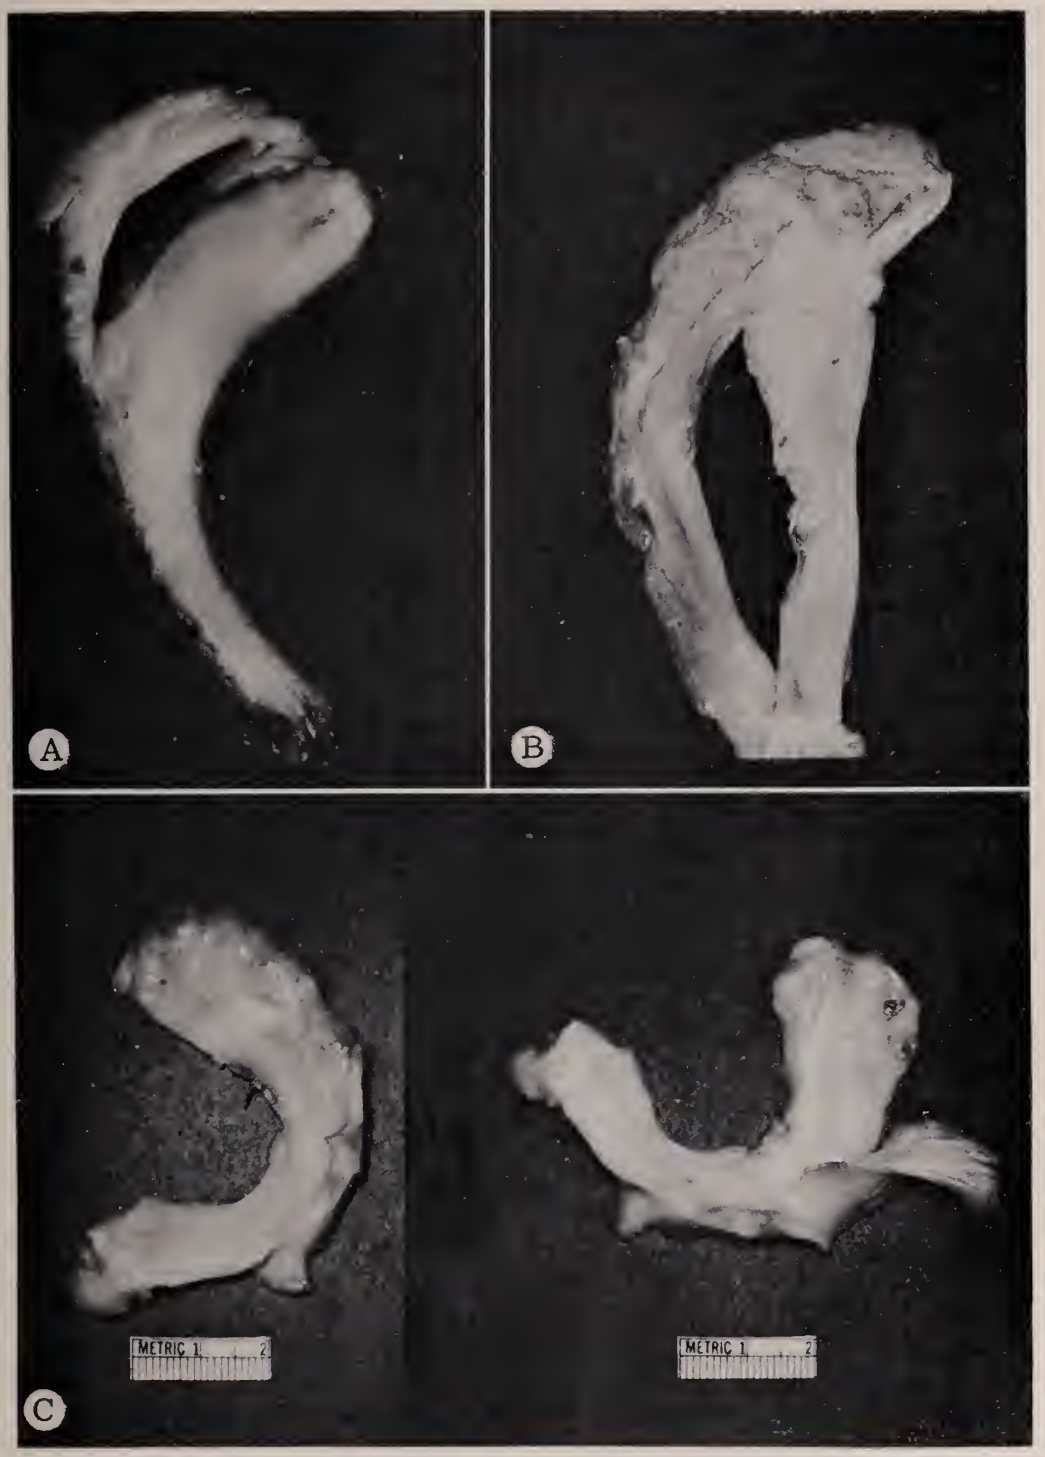

Fig. 3—*(A)* Longitudinal tear of posterior horn, medial meniscus. *(B)* Bucket-handle tear, medial meniscus. *(C)* Degenerative horizontal tear, posterior horn, medial meniscus.

and location of the tear. A description of the mechanism of injury may be helpful because symptoms often are manifested only during increased activity, such as cutting and pivoting maneuvers. With a longitudinal posterior horn tear (Figure 3 A), recurrent episodes of "giving way" associated with pain and effusion develop. Jointline tenderness and a palpable click may be detected in the various flexion and rotation maneuvers described by McMurray.[9] No locking occurs unless the tear extends anteriorly beyond the collateral ligament. When this occurs (Figure 3 B), the medial torn segment may become caught by the condyle which prevents it from returning to its normal position and gives the clinical picture of locking short of full extension.

The older athlete engaged in skiing or jogging often will present with a painful grinding sensation suggestive of a degenerative horizontal cartilage tear (Figure 3 C). A tear of the anterior horn is commoner among older patients than among younger persons. Locking is absent and the diagnostic maneuvers of McMurray[9] are negative. Disruption of the meniscus is the commonest cause of a traumatic knee effusion, and medial tears of the meniscus are approximately five times commoner than lateral tears.

Injuries to the Articular Cartilage

Injuries to the articular cartilage of the knee[10] comprise an important segment of injuries under the broad diagnosis of internal derangement. Frequently, arthrotomy for a disrupted meniscus will reveal an articular cartilage lesion as the true source of symptoms. The femur, tibia, or patella may be involved as a result of rotational stress, patellar subluxation, or direct violence. Lesions in this group consist of chondral fracture, osteochondral fracture, avulsion fracture, osteochondritis dissecans, or chondromalacia. Unlike a chondral fracture, an osteochondral fracture has a segment of underlying subchondral bone which is visible on ordinary roentgenograms. If the situation warrants, an osteochondral fracture may be reduced and fixed with a nail, K-wire, or screw (Figure 4). Osteochondritis dissecans should be considered in younger athletes who complain of aching in the knee with use and less often at rest. Recurrent effusion with activity may be noted and in some cases the fragment may fall in and out of the crater producing symptoms of intermittent locking.

Fig. 4—Osteochondral fracture of medial femoral condyle (left knee); fracture fragment repaired and held with Smiley nails.

Injuries to the Quadriceps Extensor Mechanism

In evaluating athletic injury to the knee, the quadriceps extensor mechanism must not be overlooked.[11] Lateral dislocation or subluxation of the patella occurs when the knee is flexed, externally rotated, and subjected to valgus stress. The line of action of the quadriceps is then lateral to the patella causing it to slide tangentially across the lateral femoral condyle. The misconception that patellar dislocation or subluxation occurs primarily in young women with "knock knees" or with a hereditary disposition has frequently caused this condition to be overlooked in male athletes. Symptoms and signs of patellar subluxation closely simulate lesions of the meniscus and many patients have undergone meniscectomy only to have continued disability until the correct diagnosis was made. Vague symptoms of pain or swelling or sensations of giving way or locking may be present. Often symptoms develop at the beginning of a game, before the athlete is limbered up, or the day after strenuous competition. On examination with the knee flexed, a lateral position of the patella in the groove of the anterior femur is seen. When bilateral, Hughston[11] refers to this as the "owl's eye" sign. A deficiency of the vastus medialis is usually obvious in knees with recurrent patellar subluxation. Lateral displacement of the patella with the quadriceps relaxed gives the patient a feeling of acute anxiety and he resists this maneuver. This is referred to as the "apprehension sign." Symptoms of patellar chondromalacia

lso may develop. Tangential views often will ıow the lateral position of the patella in the roove and a deficiency of the lateral femoral ondyle. Initial treatment is progressive resistive xercises for the quadriceps muscle. If symptoıatic subluxations persist, surgical procedures are ecessary to restore proper alignment of the exensor mechanism. The tight lateral retinaculum s released, the medial retinaculum is imbricated, nd often the patellar attachment is transferred ıedially.

In any injury of the knee, proper treatment includes a carefully supervised rehabilitation program until maximal recovery is attained. Return to strenuous athletics should not be allowed until the physician and patient are both satisfied that recovery is complete.

Summary

Knee injuries in the athlete are common. Early and proper diagnosis followed by adequate treatment and rehabilitation are necessary for maximal recovery. The commonest injuries are those of the ligaments, menisci, articular cartilage, and quadricep extensor mechanism.

"Mayowood"

The original land in the estate of Dr. and Mrs. Charles H. Mayo was purchased shortly after 1900 as a small acreage and the area gradually grew to more than three thousand acres which became known as Mayowood.

Construction of the house was started in 1910 and completed in the fall of 1911. The general architectural design of the house was largely the work of Dr. Charlie himself and the site was chosen because the present courtyard area was a favorite woods picnic spot for the family. The poured reinforced concrete construction necessitated the bringing to Rochester from Chicago one of the largest concrete mixers ever seen in this area.

For all the years since 1911, Mayowood has been a cultural and social center of the area. During the early years Dr. and Mrs. Charlie were the hosts and after 1940 Dr. C. W. and his wife Alice welcomed the many guests. Thirty-eight rooms are furnished with many lovely French, Spanish, English and American antiques.

In December 1965 the late Dr. and Mrs. C. W. Mayo gave their home and ten surrounding acres to the Olmsted County Historical Society. Since 1966 regular tours of the house have been scheduled. In June 1968 Mayowood was dedicated as a Minnesota State Historic Site by act of the 1967 session of the Minnesota Legislature. In 1970 Mayowood was named to the National Register of Historic Places.

Cryosurgery for Tumors of the Head and Neck

Experimental and Clinical Considerations

H. BRYAN NEEL III, M.D. AND L. W. DeSANTO, M.D.

Cryosurgery is an acceptable alternative to extirpative surgery, particularly in patients with neoplasms of the head and neck where classic resections produce losses of large portions of mandible or maxilla.[1-5] Profound cold predictably destroys benign or malignant neoplasms that are readily accessible, induces local anesthesia by rapid destruction of sensory nerve fibers, and produces hemostasis by injury to small blood vessels and capillaries.

Although cryosurgical techniques are applicable in all surgical specialties, little is known about the temporal and physical requisites for cryogenic control of cancer. Thus, we analyzed the clinical results and laboratory findings to determine the conditions of freezing required to consistently produce cell death in a target area. These data constitute the rationale for modern clinical cryotherapy.

Experimental Work

Cell Death by Freezing

Biologists have known for many years that repeated cycles of freezing and thawing produce a series of events that are lethal to cell suspensions in vitro. These events are: (1) temperature change (thermal shock), (2) formation of extracellular and intracellular ice crystals, (3) concentration of extracellular and intracellular solutes, and (4) cell shrinkage. Cells in vivo respond similarly to profound cold, but the circulation of blood, a continuous source of heat to the target area, variably and inconsistently changes the amount of cold required for cell death.

In clinical cryosurgery for cancer, the time required to destroy tumor is determined by its size. The iceball must extend at least one cm beyond the tumor into grossly normal tissues if all of the tumor is to be destroyed.[3] Tumor margins mus be accurately estimated to ensure that temperatur sensors are placed beyond the tumor, includin the deep side. A wide margin of normal tissu must be included within the area, just as a wid margin of normal tissue must be included in th specimen in the classic excision.

Temperatures Required for Cryonecrosis

It has often been stated that freezing to abou −20° C is adequate for complete necrosis of al tissues within the target area, but differential cel sensitivities to cold or variations in blood supply (or both) make that a marginal temperature a best.[6] This has been demonstrated repeatedly i several syngenic animal systems using viral an chemically induced tumors.[6,7] In these studies tumors of 1 cm in diameter and 0.5 cm of grossly normal adjacent tissues were included in the ice ball, thus eliminating variations in extent of freez ing. Because size of tumor, size of probe tip, an temperature remained constant, any differenees i tumor control would be due to other faetors depth of freeze, duration of freeze, rates of freez ing, and duration of thawing. In addition, when a large (80 sq mm) probe tip was employed, th possibility that changes in tumor boundary wer induced by movement of tumor cells in the ad vancing ice front was excluded because the tip-to tumor ratio was approximately 1:1. (Whether o not tumor cells move with the advancing ice fron is speculative.)

Freezing to tumor temperatures of −18° C an −44° C generally failed to control the tumor, bu freezing to below −44° C controlled the tumor i more than 90%* of animals studied. Similarly whether the tumor was frozen very rapidly (260 C/min) or less rapidly (100°C/min), one freez to −90°C was far more effective than one freez to −20° C. Duration of probe application prob ably has little bearing on tumor control becaus

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

*Tumor control refers to cure. Each group for which tumor control in percentage is cited consisted of 15 mice or more.

th time required to freeze to either terminal tumor tc perature at the slower rate was two to four ti es that at the more rapid rate. Optimally, these tuors should be frozen rapidly to well below -44° C and probably to temperatures of —60° C. In clinical cryotherapy, when a choice is re- q red between rapid freezing and low tumor tem- r ature (as with large tumors), the latter is the b ter alternative. Because freezing time increases v h tumor size, the freeze rate is reduced. Longer a lications of the probe will eventually reduce t temperature to the desired level.

Two and three freezes (repetitive cycles of f ezing and spontaneous thawing) of the same tumor are far more effective than one freeze. If t temperature of the probe tip approaches the b iling point of liquid nitrogen (−196° C), tu- r control increases from 50% after one freeze t between 83% and 100% after three freezes, d pending on the tumor-host system. With the s me probe tip at —60° C, one freeze cures 7% a animals whereas three freezes cure 42%. T erefore, cryosurgical systems that employ cool- g agents other than liquid nitrogen probably w uld be ineffective for cancer control.

ffects of Repeated Freezing and pontaneous Thawing

Repetitive freezing can simply enlarge the ice- all.[8] However, in the mouse-tumor studies the end oint of freezing was determined by extension of e visible iceball 0.5 cm beyond the margins of e tumor into grossly normal tissues. Hence, the ze of the iceball was constant and determined the uration of freezing. Tumor control was dependent ot on the size of the iceball but on the conditions f freezing within the frozen mass. In studies of ormal liver, local temperature measurements ere obtained, and depth of freezing and duration f thawing were both increased by repetitive freez- g. Rapid freezing and slow thawing encourage ecrystallization and formation of larger, more table ice crystals. These effect cell destruction nd ischemia, resulting in necrosis.

Probe Contact with the Tumor

When the surface of the probe tip makes con- act with most of the exposed surface of the umor, all other conditions of freezing being equal, umor control is most effective. At —180° C, a probe tip with a tip-tumor contact ratio of about 1:1 produced cures in 82% of animals studied, whereas a tip-tumor ratio of one fourth that size produced cures in only 54%.

The Effects of Ischemia in Cryosurgery

Because blood is a continuous source of heat to the target area, limitation or exclusion of blood flow should potentiate cryonecrosis. Temporary ischemia, induced in the liver by clamping the porta hepatis, quadruples the volume of cryonecrosis and assures death of all cell types within the target.[9] With temporary ischemia, tumor implants in the livers of syngenic rats were successfully eradicated by repetitive cryoprobe applications.[10]

Clamping is impractical and often not feasible in many anatomic regions. Therefore, we evaluated tumor control after local injection of pharmacologic doses of epinephrine.[7] Subcutaneous fibrosarcomas in a syngenic murine system were frozen after local infiltration of epinephrine and clamping of the tumor vascular pedicle during freeze-thaw cycles. Tumor control in these two groups was compared with controls. No significant differences were observed between the two groups that underwent ischemia. Two freezes in the presence of ischemia were equivalent to three freezes without ischemia, producing tumor control in 95% of 40 mice. This represents not only a significant conservation of effort but also a marked potentiation of heat extraction, all other conditions being the same. Whereas small increases in depth of freezing were produced, thaw time was clearly prolonged. Passy et al.[11] found that injecting epinephrine in saline beneath the oral mucosa of dogs prior to cryoprobe application significantly enhanced cryonecrosis of these tissues. Indeed, all data indicate that local administration of epinephrine prior to cryosurgery markedly potentiates the effects of cryosurgery and may be a useful adjunct to cryogenic treatment of neoplasms in patients.

Immunologic Considerations

Cryosurgery and cryonecrosis produce a definite and specific antibody response to normal tissues and tumor. This has led to the term "cryo-immunization."[12] Among normal tissues, the coagulating gland of the rabbit has been most extensively studied. After cryonecrosis in situ, circulating antibody specifically directed against components of that organ has been detected by passive hemagglutination and gel-diffusion techniques.[12] This auto-antibody is species- and tissue-specific. The antibody was detected in the serum within four days after cryotherapy, and the titers reached a maximal level by seven to 10 days. Antibody titers declined thereafter. Antibody ac-

tivity was predominately 19S early in the postoperative period; later, 7S activity was detected. This corresponds to the pattern observed after antibody induction in general. Subsequent cryotherapy of the same tissue led to a "booster" effect, with production of higher and more prolonged elevations of 7S antibody.

Of particular interest in the treatment of malignant neoplasms is the differential tumor-specific immune response observed after cryonecrosis of both viral and chemically induced tumors in several animal systems.[13] This apparently results from prolonged exposure to tumor-specific transplantation antigens as compared to complete excision. Consistently greater immunity was seen after tumor necrosis in situ by cryosurgery or by ligation of tumor than by tumor excision, and the magnitude of the immune response was the same after treatment by either method. This suggests that cryosurgery does not significantly alter tumor antigen(s) and that the immunologic effects are induced by mechanisms which involve rapid tumor kill in situ and subsequent absorption of tumor-specific antigens. The increased immunity seen after cryosurgery is consistently demonstrable in several murine systems and may also explain the striking tumor regressions reported after cryosurgery of human tumor.

The mechanisms of so-called cryo-immunization are not clear, but because cryosurgery and ligation appear to have equivalent effects, duration of host exposure to tumor-specific transplantation antigens in situ appears to be a factor. Both techniques lead to ischemic necrosis and delayed slough of tumor 1½ to 2½ weeks after treatment. Necrosis may produce molecular changes in antigen or may liberate normally sequestered antigens into blood, lymph or both. Antigen release can be induced by immune complex formation and cell lysis in the presence of complement.

It has been impossible to produce regression of established tumors by immunologic means alone, but in the near future, immunotherapy may become an important adjunct to surgery. Because tumor-specific antigens have been demonstrated in many human tumors, the immunologic response of patients to cryotherapy of cancer should be studied.

Clinical Cryosurgery

At the Mayo Clinic DeSanto[3] has recently reviewed the results of cryotherapy in 44 patie with neoplasms of the head and neck regi Eight patients with squamous cell carcinoma w treated for cure, and 27 (most with squam cell carcinomas) were treated for palliation. Cr surgery was employed as an adjunct to excisio surgery in nine patients with nonmalignant mors: two with angiofibromas of the nasophary six with squamous papillomas of the larynx, a one with a hemangiopericytoma involving nose.

Technique

All cryosurgery is performed in the operati room with sterile technique. A self-pressuriz cryosurgery unit, which utilizes liquid nitrogen heat extraction (Brymill model SP5), is used, a the choice of cryoprobe depends on the site, si and accessibility of the tumor. Open-tip spr probes are used for lesions involving the anter oral cavity, for mobile portions of the tongue, a for those within maxillectomy cavities. Gros normal tissues beyond the target site are p tected by insulation with Styrofoam and Vaseli impregnated gauze. Closed probes are used lesions involving the base of the tongue and hyp pharynx. These probes are applied to the surfa of the tumor or inserted into it.

Tissue temperatures are continuously monitor by needle thermal sensors placed one to two from the gross margins of the tumor. Tumors a frozen repetitively, at least three times, and lowed to spontaneously thaw prior to refreezir When closed tips are employed, repetitive pro applications at several sites are necessary to ad quately freeze tumors larger than four cm diameter.

Recently, probes have been developed wi small apertures that allow spraying of the targ with liquid nitrogen. Although open-tip spr techniques effect cryonecrosis of more tissue in shorter time, sprays are difficult to contr Chandler and Hiott[2] reported that closed pro tips of about one cm diameter are ideal for mc carcinomas of the oral cavity.

The operative procedure is generally carried o with patients under general endotracheal anesth sia. Patients with accessible cancers involving t mucous membranes of the anterior oral cavity a patients with recurrent cancers in maxillecton cavities are often anesthetized with intraveno analgesic agents.

Clinical Application and Outcome

Deeply infiltrating tumors with poorly defined margins are seldom suitable for cryosurgery. Because the margins of such neoplasms are cryptic, extensive freezing is required and several weeks pass before the eschar sloughs and the depths of the wound can be evaluated for residual tumor.

Tumors caudal to the tonsillar fossa within the base of the tongue and in the hypopharynx are not suitable for cryosurgery because visualization of the entire tumor for probe applications is partial, at best. However, tumors of the buccal mucosa, retromolar trigone, floor of the mouth, mobile tongue, and the palate are particularly suitable for cryotherapy.

Osseous tissues are readily destroyed by repetitive freezing, so that cryosurgery is an attractive alternative to excisional surgery. Tumors that involve bone, such as those of the anterior floor of the mouth abutting the mandible or those of the hard palate, are ideal for treatment because they are the most accessible. Indeed, Marcove and Miller[14] have shown that cryosurgery can eradicate primary and metastatic tumors of bone.

Cryosurgery of large tumors of the oral cavity and pharynx produces edema which may lead to upper airway obstruction. The following case is illustrative:

A 78-year-old white man had a two by three cm exophytic carcinoma of the right retromolar triangle (figure). He was asymptomatic. Because excisional surgery would have required composite resection of regional tissues including the mandible, he refused operation. Cryosurgery was performed with the patient under general anesthesia, with liquid nitrogen spray freezing delivered through an open-tip probe. The tumor was frozen to below −30° C three times and allowed to spontaneously thaw between freezes. When the patient awoke from the anesthesia, he experienced a massive swelling of the tongue and lateral pharyngeal wall. The swelling led to upper airway obstruction, and he required an immediate tracheotomy. The tracheotomy cannula was removed five days later, and the patient's recovery was uneventful. He is free of disease 18 months after treatment.

Profound cold induces hemostasis, yet major hemorrhage can occur after cryosurgery. This hazard is seen most frequently in patients in whom irradiation or tumor invasion or both have compromised the viability of large vessels.[2,3] Gage et al.[15] studied the effects of complete freezing of arteries, including the femoral, carotid, and hepatic vessels and the abdominal aorta, in dogs. They found no arterial dilatation at any time after cryosurgery during the study period of one year. They saw no arterial thrombosis in large caliber arteries but observed it in branches of the hepatic artery. They concluded that cryotherapeutic techniques could be safely applied to tumors surrounding large blood vessels that supply vital organs.

As an agent for palliation, cryosurgery generally produces disappointing results. Relief of pain, reduction of bulky tumor masses, and reduction of bleeding are usually accomplished. However, three patients in DeSanto's[3] series required further therapy because of postcryosurgical bleeding, and one developed an oral-cutaneous fistula. In three other patients, cryosurgery for local recurrences after maxillectomy reduced the size of the tumor so that these patients were able to again wear maxillary prostheses.

Cryosurgery is a useful adjunct to excisional surgery of vascular neoplasms. The coagulation necrosis induced by profound cold produces vasoconstriction, stasis, and clotting within small vessels.[16] The target area may then be safely excised or curetted. This has been the experience in the two patients with juvenile nasopharyngeal fibromas and in the patient with the hemangiopericytoma involving the nose.

Of the eight patients with cancer treated for cure, seven have had complete tumor control during the observation period of six to 20 months. One died after carotid rupture and ligation one month after cryotherapy. Radiation or excisional therapy (or both) failed to control tumor in this

Figure—Exophytic squamous cell carcinoma (2 by 3 cm) involving the right retromolar trigone. Lesion was treated successfully by cryosurgery.

patient and in six others of the group.

In a series of 28 patients with oropharyngeal eaneer treated for eure, Chandler and Hiott[2] indueed eontrol of the tumor in 61%, but follow-up was less than two years in most eases. There was one operative death. Gage[4] reported that 17 of 25 (68%) patients with oral eaneer treated by eryosurgery had survived for two years or more, a survival equivalent to that after eonventional surgical therapy. There were no operative deaths. All tumors were staged before operation using the TNM elassifieation. Their results indieate that the ehanee of sueeess with eryosurgery, as with all forms of treatment, is related to the size of the lesion.

Summary

If malignant disease is to be eonsistently controlled by cryosurgery it is important to utilize low probe-tip temperatures, large probe tip-to-tumor eontact surfaees or liquid nitrogen sprays, repetitive probe applieations, spontaneous thaw between freezes, freezing to tumor temperatures below −30° C, and rapid rates of freezing. In perimental tumor-host systems, ischemia indu either by loeal administration of pharmacolo doses of epinephrine or by temporary clamp markedly potentiates the effeets of freezing a thawing. A definite tumor-specifie transplan tion immune response follows eryonecrosis tumor in situ. This exceeds the immune respo seen after exeision of tumor.

Cryosurgery is an aeceptable alternative extirpative surgery or radiation therapy in selec patients with oral and pharyngeal eancers. Ho ever, it should not beeome a standard method treatment for eaneer until the eure rate with t therapy can be compared with that of eonventio therapy for similar tumors. Tumors must aeeessible, and the likelihood for cure by cr therapy is related to the size of the neoplasm. F palliation, eryosurgery generally relieves pain a by redueing tumor bulk, permits deglutition a better oral hygiene. The eomplieation rate amo this group of patients is high.

It's the Law

Postoperative Ileus

A patient was admitted to the hospital for removal of a small cyst from his kidney. After surgery he developed paralytie ileus. Six days after the surgery he vomited, aspirated and died related to a eondition of severe paralytie ileus.

Medieal experts brought in to testify agreed that a patient should not die as a result of postoperative ileus if standard medieal practiees were followed. Family of the patient was awarded $575,000 by a California jury in a suit against the physician and the hospital. The physician and hospital were deemed negligent in not summoning another physician when it beeame apparent that the treatment being rendered was ineffeetive.

Pyridoxine-Responsive Anemia

A Preleukemic Manifestation?

H. CLARK HOAGLAND, M.D. AND JAMES W. LINMAN, M.D.

PYRIDOXINE-RESPONSIVE anemia was first described by Harris and associates[1] in 1956 and is now generally recognized as a distinct entity, usually acquired. The manifestations of pyridoxine-responsive anemia differ from those of pyridoxine deficiency in experimental animals and infants; the latter states are characterized by dermatitis and convulsions and respond to physiologic doses of pyridoxine, whereas the pyridoxine-responsive anemias are not associated with systemic manifestations and pharmacologic doses are needed to induce hematologic responses. Harris and his colleagues[2,3] have reviewed 72 cases of pyridoxine-responsive anemia; variability within this group was striking, and only 25 of the 72 patients were considered to be typical of the prototype case. They stated that "none of the seventy-two patients with pyridoxine-responsive anemia has been found to have or to develop leukemia."[2]

Recently, it has been emphasized that acquired sideroblastic anemia may represent an early stage of a neoplastic process, that is, a preleukemic lesion.[4] There are a number of isolated reports of cases of "refractory anemia" terminating with acute granulocytic or myelomonocytic leukemia, and it has been suggested that there exists more than a coincidental relationship between these entities.[5-8] Since certain pyridoxine-responsive anemias are types of acquired sideroblastic anemia,[9] it might be expected that some of these patients would eventually develop leukemia.

During the past six years we have seen at the Mayo Clinic over 250 cases of "primary refractory anemia." The majority have had demonstrable iron-overload and ferrokinetic patterns of ineffective erythropoiesis. Most of these patients had therapeutic trials with pharmacologic doses of pyridoxine as well as other hematinics, without appreciable responses. Included in this group are five patients who had hypochromic-microcytic, pyridoxine-responsive anemias; in contrast to previously reported cases, three of these patients either had leukemic changes in their bone marrow at the onset of their anemia or developed them later. The fourth patient exhibited sufficient changes to be classified as preleukemia;[10] followup on this patient has been less than one year. Only one of these five patients had no evidence of leukemia; there was no followup in this case as he died four months after his initial examination, from causes unrelated to his anemia. The peripheral blood smears and bone marrow specimens in these cases were reviewed independently by three experienced hematologists who had no prior knowledge of the patients' suspected diagnoses; there was uniform agreement concerning the presence of leukemia.

Case Reports

Case 1

This 58-year-old man was referred to the Mayo Clinic because of progressive chronic obstructive lung disease of 25 years' duration. He had lost 11.5 kg. in weight over the preceding 12 months; he denied having anorexia, fever, or increased sweating. He was a thin, pale, chronically ill man who had obvious signs of emphysema. There was no hepatosplenomegaly or adenopathy. In addition to findings compatible with obstructive lung disease with a diffusion defect, laboratory studies demonstrated a hypochromic-microcytic, non-iron-deficient anemia with a hemoglobin of 10.5 gm/100 ml (see Table for additional laboratory studies). The bone marrow revealed normoblastic erythrocytic hyperplasia and was otherwise not remarkable. He was started on oral pyridoxine, 50 mg daily, and in two months his hemoglobin had increased to 14 gm/100 ml. Shortly thereafter, the patient committed suicide; an autopsy was not performed.

Case 2

This 76-year-old man was referred to the Mayo Clinic because of back problems resulting from an automobile accident some years before. He had been anemic for one year, had been given iron, but had not improved. Physical examination revealed moderate pallor, pigmentation of

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

This investigation was supported in part by Training Grant T1 AM-5538 from the National Institutes of Health, Public Health Service.

the skin, and significant hepatomegaly; the spleen was not palpable. A liver biopsy revealed hemosiderosis without significant cirrhosis. Pertinent laboratory findings are listed in the Table. The anemia was hypochromic-microcytic, and the bone marrow revealed erythrocytic hyperplasia with megaloblastoid features (Figure 1), plus an increase in blast cells and atypical megakaryocytes. He was given oral pyridoxine, 100 mg/day, with no response over a two-week period. He was then begun on 50 mg/day intramuscularly, and over the ensuing eight days his reticulocyte count increased from 1.7 to 11% and his hemoglobin from 6.2 to 8.2 gm/100 ml. Despite continued therapy for five months, his peripheral erythroid values fell and serial bone marrow examination continued to demonstrate changes of myelomonocytic leukemia with a predominant erythroleukemic component. Transfusions were necessary over the next three months, and he died elsewhere seven months later of an acute myocardial infarction. A partial autopsy did not include examination of the marrow.

TABLE

Summary of Laboratory Data

	Case 1	Case 2	Case 3	Case 4	Case 5
Leukocytes	8,000	4,000	5,000	5,500	6,200
Platelets	308,000	147,000	236,000	Incr	95,000
Leukoerythroblastosis	0	+	0	0	+
Anisocytosis	2+	3+	3-4+	3+	4+
Poikilocytosis	2+	3+	3-4+	3+	4+
Hypochromia	3+	2+	3+	2+	2+
Microcytosis	2+	0	3+	2+	2+
Hemoglobin electrophoresis	Normal	Normal	Normal	Normal	Not done
Serum iron, μg/100 ml	160	144	226	130	211

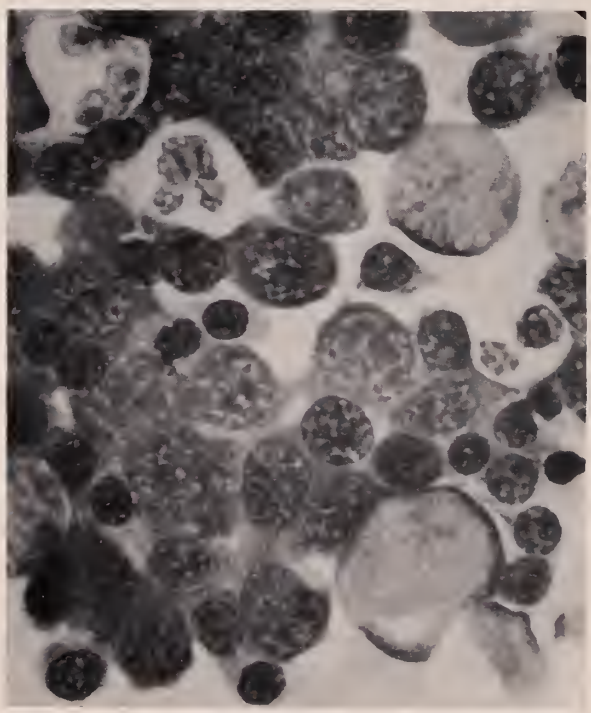

Fig. 1—Megaloblastoid erythrocytic hyperplasia with an increase in immature precursors in Case 2.

Case 3

A 77-year-old man, followed at the Mayo Clinic for many years because of arteriosclerosis obliterans, was first found to be anemic in April 1969, when he complained of increasing weakness and vertigo during the preceding two months. He was moderately obese. The liver and spleen were not palpable. Pertinent laboratory data are listed in the Table. The anemia was of the hypochromic-microcytic, non-iron-deficiency variety with a hemoglobin of 9.8 gm/100 ml. His bone marrow was hypercellular with an overabundance of immature megaloblastoid erythrocytic precursors together with such qualitative changes as increased numbers of siderocytes and sideroblasts, cloverleaf nuclei, and karyorrhexis (Figure 2). Several observers concluded that these changes were those of preleukemia. The patient was started on pyridoxine, 100 mg twice daily by mouth. Four months later, his hemoglobin was 13.7 gm/100 ml, with a red cell count of 3,840,000/cu mm. However, a repeat bone marrow examination still revealed clear-cut erythrocytic abnormalities with hyperplasia, maturation defects, and megaloblastoid features plus atypical megakaryocytes. These changes were again interpreted as those of an evolving myeloproliferative disorder (that is, preleukemia).

Case 4

This 49-year-old man, who had a long history of pemphigus, steroid-induced diabetes, and arteriosclerotic cardiovascular disease, was seen at the Mayo Clinic because of anemia of eight months' duration which had necessitated transfusion. Laboratory studies revealed a microcytic anemia with iron overload (hemoglobin 9.7 gm/100 ml) (see Table for additional laboratory data). The marrow was diagnostic of the erythroleukemic form of myelomonocytic leukemia (Figure 3). The patient was started on pyridoxine, 100 mg twice daily intramuscularly. Six days after pyridoxine was started, the reticulocyte count had increased to 8.3% and one month later the hemoglobin level was 13.0 gm/100 ml. Seven months later he died of a myocardial infarction, at which time the hemoglobin concentration was 10.8 gm/100 ml and the platelet count was 81,000/cu mm. A partial autopsy did not include examination of the bone marrow.

Case 5

This 44-year-old woman had a long history of discoid lupus erythematosus. Anemia had been noted prior to her examination at the Mayo Clinic. Treatment with a variety of hematinics including folic acid with vitamin B_{12} was unsuccessful, and periodic blood transfusions were required. Because of a hypochromic-microcytic, non-iron-deficient anemia with a hemoglobin of 7.0 gm/100 ml (see Table), she was given pyridoxine, 100 mg daily by mouth. Her hemoglobin level increased and there was no need for further transfusions. Two years later the anemia worsened and transfusions were again necessary to maintain satisfactory peripheral erythroid values. At this time, the bone marrow showed bizarre erythropoiesis with an increased number of blast cells, plus atypical megakarocytes (Figure 4), and was interpreted to be diagnostic of leukemia. Androgen therapy was begun (400 mg of testosterone enanthate once weekly), and five months later her hemoglobin level had

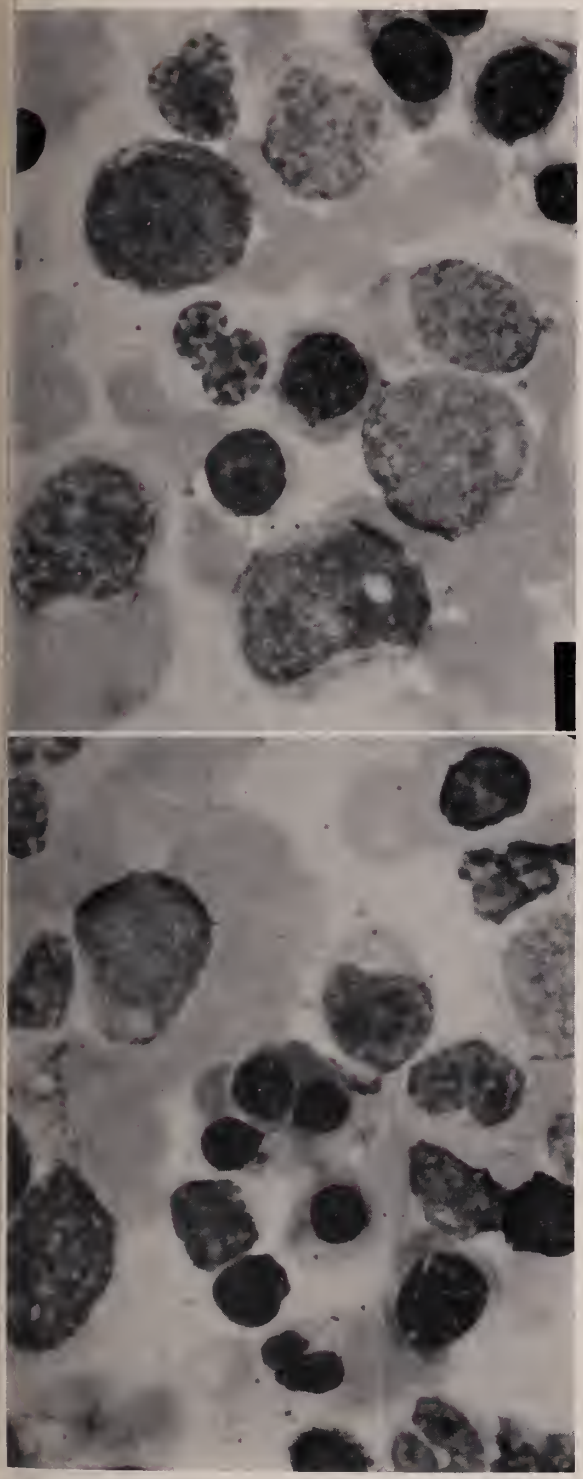

Fig. 2—Examples of marrow abnormalities in Case 3 (cloverleaf nuclei, megaloblastoid erythrocytic precursors, and maturation abnormalities).

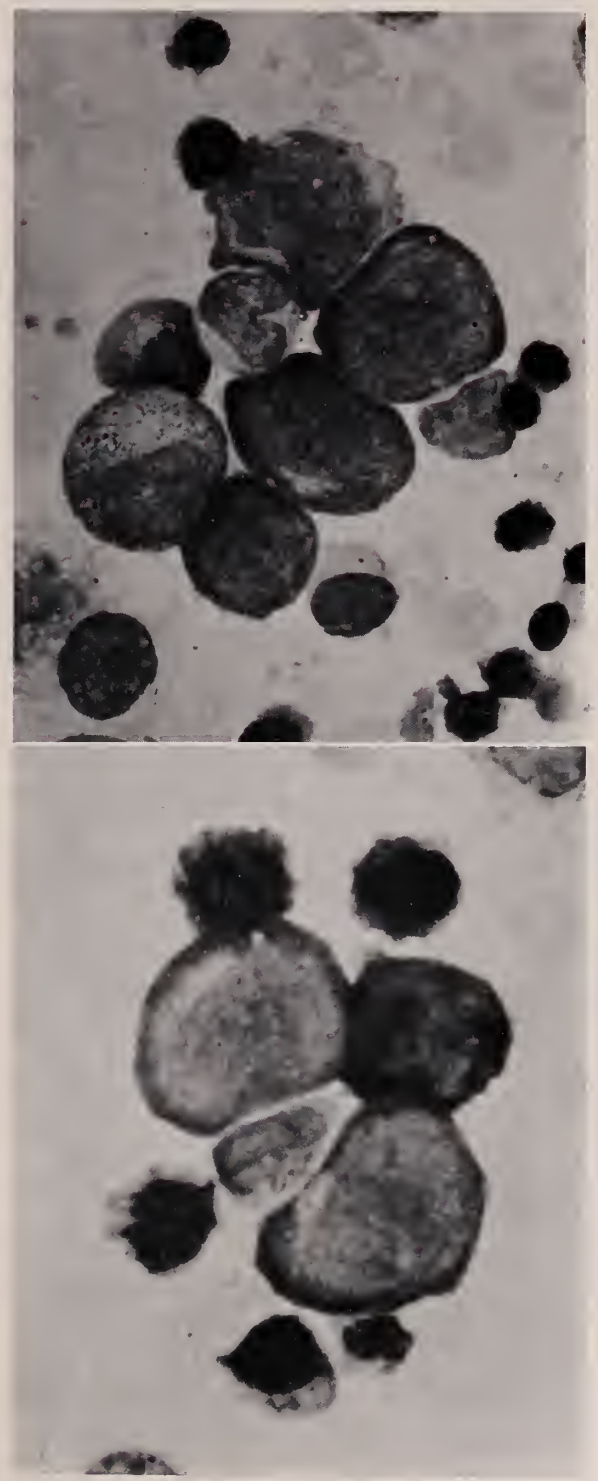

Fig. 3—Atypical erythrocytic precursors and overabundance of immature cells in Case 4.

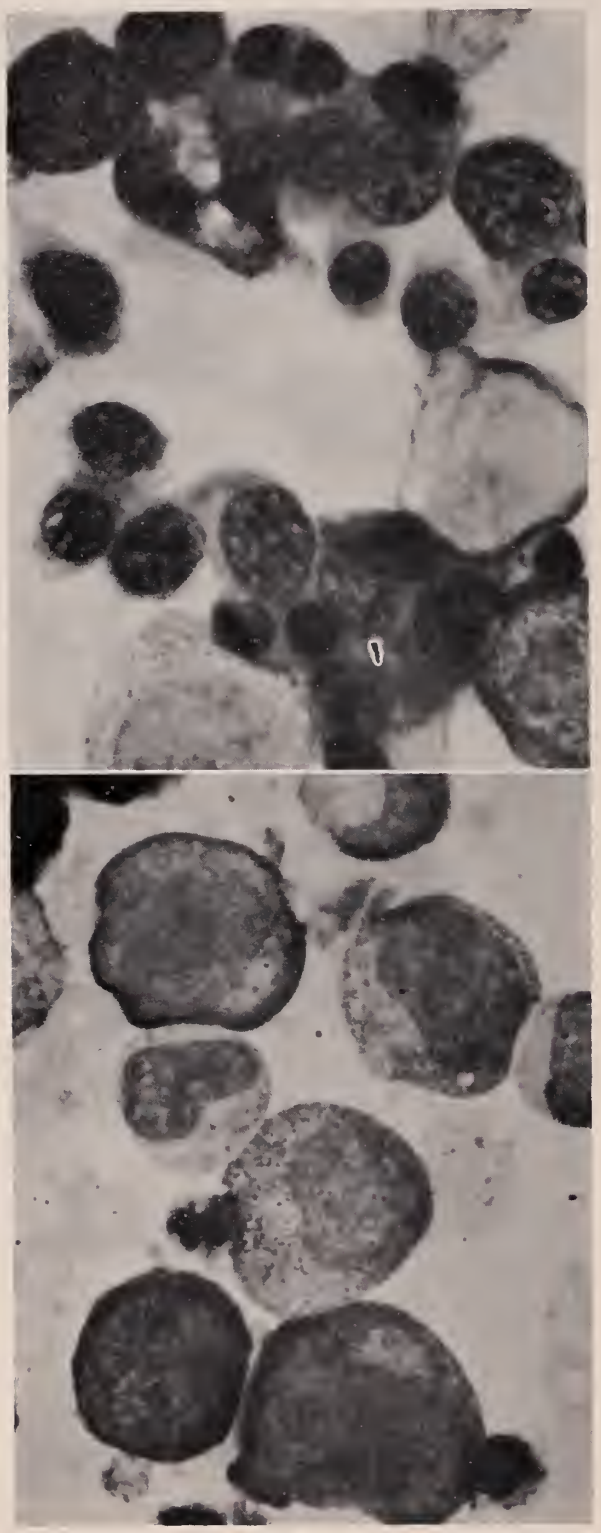

Fig. 4—Bizarre erythropoiesis with increased numbers of immature cells in the marrow of Case 5.

increased to 12 gm/100 ml; however, the qualitative abnormalities of her red blood cells persisted. She is still alive five years after onset of the anemia.

Discussion

All five of our patients were over 40 years of age, and four were men. Each presented with symptomatology directly related to anemia. All had normal leukocyte counts, and four had normal platelet counts. Two patients had evidence of leukoerythroblastosis in their peripheral blood. Each patient displayed marked anisopoikilocytosis with clear-cut hypochromia and microcytosis. Serum iron determinations were normal or elevated in every patient, and hemoglobin electrophoreses were normal. The last findings together with negative family histories and the onset of the anemia during adulthood serve to exclude thalassemia. Each of the four patients who had leukemic bone marrow manifested changes of myelomonocytic leukemia or its preleukemic phase:[10,11] bizarre megaloblastoid erythropoiesis, abnormal granulopoiesis with an overabundance of blasts and progranulocytes, and normal to increased numbers of atypical megakaryocytes. Three patients responded to pharmacologic doses of pyridoxine with a substantial rise in their hemoglobin levels to near normal; the remaining two patients exhibited reticulocytosis and a decrease in transfusion requirements, but their hemoglobin concentrations changed only moderately. Three of the five patients have subsequently died from diseases unrelated to their hematologic problems. Two patients are still alive; one has relapsed and is requiring additional therapeutic measures for her refractory anemia. Case 3 has a hemoglobin level of 13.7 gm/100 but continues to exhibit qualitative abnormalities in the peripheral blood and preleukemic changes in the bone marrow.

If suboptimal hematologic response is accepted as one of the diagnostic criteria, many "sideroblastic anemias" can be designated "pyridoxine-responsive anemias." The marked variations in presentation and response to pyridoxine attest to the heterogeneity of this group of anemias.[2,4,9,12] We believe that responsiveness to pharmacologic doses of pyridoxine may, in some cases, be characteristic of leukemia. Each of our patients with leukemia had erythrocytic abnormalities with megaloblast-like or megaloblastoid features in the face of normal serum vitamin B_{12} or folate levels or unresponsiveness to the administration of these

agents. Therefore, one wonders if certain of the reports of patients with pyridoxine-responsive anemia and "megaloblastic" morphology were not examples of neoplastic changes.

Recent studies of the pyridoxine-responsive anemias point to one, and possibly two, enzymatic defects in hemoglobin synthesis.[12,15] In the formation of delta-aminolevulinic acid from succinate and glycine, the enzyme aminolevulinic acid synthetase, which requires pyridoxine as a cofactor, has been found to be defective (Figure 5). There is suggestive evidence in this group of patients that heme synthetase, which is needed for the linking of iron and protoporphyrin to form heme, also functions abnormally. However, these observations do not detract from the possibility that the basic disorder may be leukemic, for many enzymatic defects have been associated with malignant processes.

The red cell enzymatic defects in the pyridoxine-responsive anemias may result from iron overload.[12,14] These enzymes are located in the mitochondria where iron accumulation could inhibit their activity, and when excess iron is reduced by phlebotomy, enzyme function more closely approaches normal. However, it is difficult to know which is the primary mechanism. Does iron overload cause or is it in turn caused by enzyme abnormalities? Because three of our five patients with pyridoxine-responsive anemia had leukemic bone marrows and a fourth had changes of an evolving myeloproliferative process, we believe a neoplastic change to be the primary factor in these cases with iron overload and enzymatic defects both resulting therefrom. Such a concept lends support to the malignant potentiality of the primary sideroblastic anemias.[16]

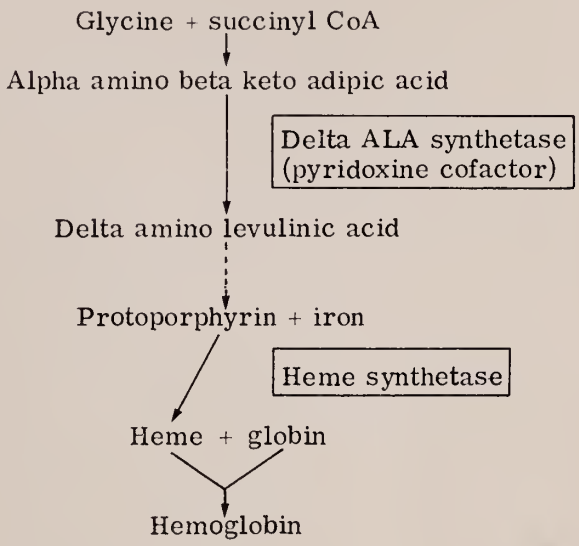

Fig. 5—Site of action of two enzymes which may be defective in pyridoxine-responsive anemias; figure shows route of protoporphyrin and hemoglobin synthesis.

Referred Pain to the Ear

EUGENE B. KERN, M.D.

EAR PAIN or otalgia caused by an acute inflammation of the middle or external ear is often easily diagnosed on physical examination. The symptom of earache, however, can be caused by disorders which arise distant from the ear in question. When the origin of pain is remote from the area of the disease process, it is called referred pain. Patients complaining of otalgia in whom no obvious evidence of ear disease can be found must be examined for lesions other than those associated with the ear. Inflammatory or malignant lesions of the nasopharynx, base of the tongue, or larynx may cause referred pain to the ear and must therefore be excluded.

When a patient has an earache, particularly a mild one, he usually can indicate only that the pain is in a general area of the external ear. The patient should be asked to localize the specific site of the pain because some patients misinterpret what is meant by ear pain and point to the temporomandibular joint, angle of the mandible, or the region of the temporal artery, thereby providing the examiner with an important clue as to the cause of the pain. When the source of the ear pain cannot be found on examination of the ear, the sites from which the referred pain may arise must be considered (Table and Figure).

The fifth, seventh, ninth, and 10th cranial nerves have sensory fibers in the regions of the auricle, the external auditory canal, tympanic membrane, and middle ear. There is considerable overlap in the distribution of these sensory fibers. Also, the second and third cervical nerves supply sensation to the postauricular region, while the auriculotemporal branch of the fifth nerve innervates a large region in front of the auricle of the external ear and around the temporomandibular joint. Usually, when examining a patient who has an earache but no inflammation in his middle or external ear, one cannot determine the precise sensory nerve distribution that the pain is being referred through until a lesion has been found. It is imperative before looking further that the external auditory canal be examined carefully so as not to overlook some small lesion (for example, furuncle or cancer).

Fifth Cranial Nerve (Trigeminal)

Dental disease may cause earache referred through the fifth cranial nerve (trigeminal). Molar impaction and infection are perhaps the most common causes of referred ear pain. Sinus inflammation in an antrum or in a posterior ethmoid or tumors in these areas may cause referred otalgia through the fifth cranial nerve, although this is

TABLE
Sensory Distribution Accounting for Referred Pain to the Ear

- Fifth cranial nerve (trigeminal nerve, mandibular division)
  - Oral cavity and floor of mouth
  - Teeth (lower)
  - Palate
  - Tongue (anterior two thirds)
  - Mandible (lower)
  - Temporomandibular joint
  - Preauricular region
  - Anterior tympanic membrane
- Seventh cranial nerve (facial nerve)
  - External auditory canal
  - Postauricular region
  - Middle ear (?)
- Ninth cranial nerve (glossopharyngeal nerve)
  - Tonsil
  - Base of tongue (posterior one third)
  - Nasopharynx
  - Eustachian tube
  - Pharynx (throat)
  - Middle ear
  - Mastoid air cells
  - Posterior tympanic membrane
  - External auditory canal
  - Postauricular region
- Tenth cranial nerve (vagus nerve)
  - Hypopharynx (throat)
  - Larynx
  - Trachea
  - Posterior tympanic membrane
  - External auditory canal
  - Postauricular region
- Cervical nerves (C-2 and C-3)
  - Postauricular region
  - Skin over mastoid region
  - Skin over anterior neck and thyroid region (suprahyoid and infrahyoid regions)

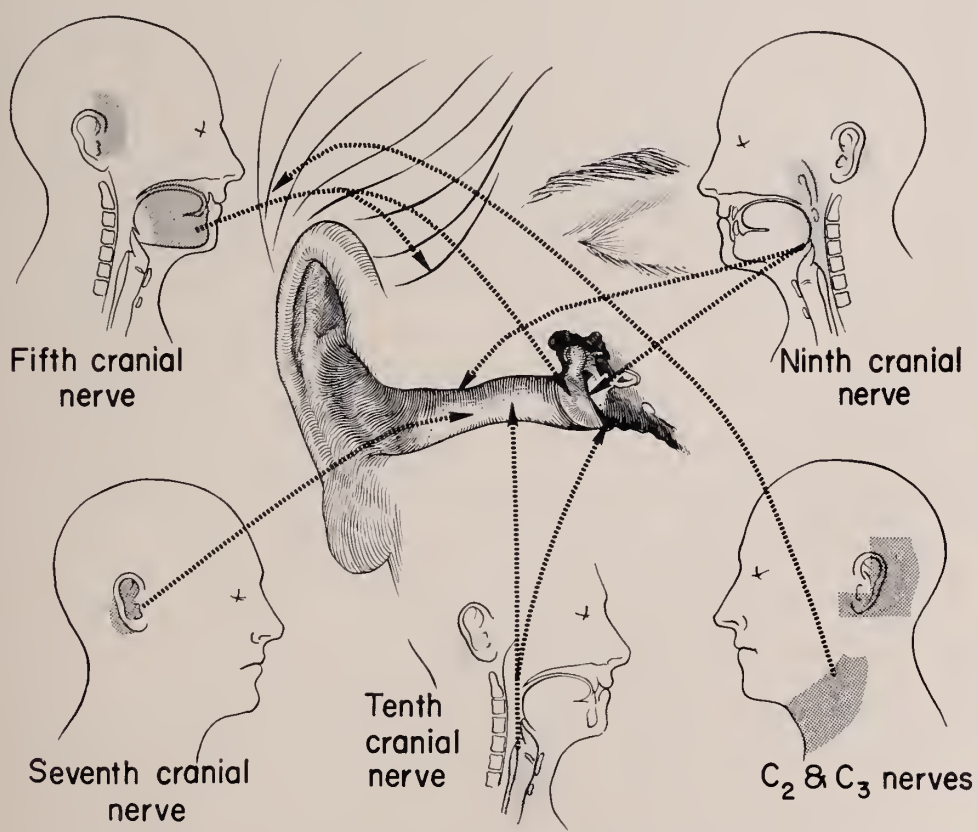
Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
See editorial, page 913.

probably rare. Acute or chronic disturbances of the temporomandibular joint may produce ear pain that is referred through the auriculotemporal branch of the fifth cranial nerve.

Seventh Cranial Nerve (Facial)

The seventh cranial nerve (facial) can cause otalgia principally in herpetic eruptions from viral infection of the geniculate ganglion. The pain is transient and often is overshadowed by other manifestations, particularly by the seventh-nerve palsy. Other lesions could touch the sensory branches of the facial nerve and produce otalgia; however, this is probably uncommon.

Ninth Cranial Nerve (Glossopharyngeal)



A lesion in the distribution of the ninth cranial nerve (glossopharyngeal), the nasopharynx, eustachian tube, the region of the palatine tonsils, adjacent base of the tongue, or the lingual tonsils, may cause earache by way of the glossopharyngeal nerve. The inflammatory process of this region usually accounts for the earache that may occur in the early convalescence from tonsillectomy. Afflictions of the ninth cranial nerve, such as glossopharyngeal tic, also may cause earache. The pain and discomfort of glossopharyngeal tic is sharp, short, and lance-like and can be precipitated either by drinking a cold liquid or by swallowing.

Tenth Cranial Nerve (Vagus)

A patient with an inflammatory or neoplastic lesion in the epiglottis of the larynx, in the pyriform sinus (hypopharynx), or in the trachea often complains of earache on the involved side. The reference is through the superior laryngeal branch of the vagus nerve, the 10th cranial nerve. Frequently, a patient with this problem also complains of hoarseness. This symptom allows the examiner to direct his attention to the region that is producing referred pain to the ear.

Cervical Plexus (C-2 and C-3)

The second and third cervical nerves also are pathways for referred pain to the external ear and the soft tissues in the mastoid process; inflammation or mass lesions of the thyroid may produce re-

Figure—Diagram of pathways from various sensory distributions accounting for referred pain to the ear.

ferred pain to the ear. Otalgia may be an early manifestation of thyroid carcinoma especially in children. Pain is mediated by C-2 and C-3 through the cervical plexus to the auricle. The upper cervical nerve roots supply the postauricular region. Pain due to their irritation, for example, cervical spondylosis or sternocleidomastoid myalgia, may be referred to the ear or mastoid process. There is also the possibility that otalgia may be due to an autonomic imbalance along the course of blood vessels related to these parts.

Summary

Pain may be referred to the ear from sensory fibers of the fifth, seventh, ninth, or 10th cranial nerves or from the cervical plexus (C-2 and C-3). If the patient can point to the painful site, this is an important clue to the cause. If the source of the pain is not readily determined from the examination of the external ear, tympanic membrane, or preauricular and postauricular regions, then distant sites must be examined because the pain may be the result of an occult malignancy. These distant sites involve the sensory distribution of the fifth, seventh, ninth, and 10th cranial nerves and the second and third cervical nerves. Common sources of this referred pain are the oral cavity (teeth, tongue, tonsil), temporomandibular joint, nasopharynx, and perilaryngeal regions.

Request for Physican's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers has received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Because of limitation of space, pictures oriented horizontally are preferred. All pictures will be returned if identified with the name and address of the physician. Please submit your pictures as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

Farrell Stiegler, M.D.
Cover Editor

Honorary Doctoral Degree

An honorary doctoral degree from the University of Munich, Germany, was recently bestowed on Cecil J. Watson, M.D. of Minneapolis for his important research contribution to medical science. The degree was awarded in conjunction with the 500th anniversary of the University.

Dr. Watson is the past head of the department of medicine at the school of medicine at the University of Minnesota and is presently the senior consultant to the University's medical unit at Abbott-Northwestern Hospital.

He was the only American among the seven physicians so honored.

In 1930-32 Dr. Watson was a resident physician at the University of Munich where he studied under Nobel Prize Winner, Dr. Hans Fischer, who, until his death, was a world authority on bile pigments and hemoglobin metabolism. Since then Dr. Watson has become a leading authority in the study and treatment of liver diseases and in the study of bile pigments and porphyrins and it has been in these areas where he has conducted significant medical research.

Management of Gastrojejunal Ulcer

A Review of 106 Cases

DAVID D. DuBOIS, M.D. AND OLIVER H. BEAHRS, M.D.

In recent years much knowledge about gastrojejunal ulcer disease has become available. For many years the frequency of recurrent gastrojejunal ulcers seemed to be one of the most important if not the only consideration in selecting the type of operation for duodenal ulcer. Recurrent peptic ulceration occurs after approximately 2% of operations for gastric ulcer and five to 10% of operations for duodenal ulcer. Of patients with recurrent peptic ulceration, 95% are those originally operated on for duodenal ulcer. Today factors other than recurrence are important in selecting the appropriate operation for peptic ulceration. These factors include maintenance of weight, degree of postprandial symptoms, diarrhea, and overall condition of the patient.

Gastrojejunal ulceration represents a surgical failure of the previous operation for peptic ulcer disease. Although some authors have reported limited success with the medical management of gastrojejunal ulcers, most favor surgical treatment of the ulcer once the diagnosis has been established: first, because the original ulcer was a surgical problem and, second, because the initial surgical treatment was unsuccessful.

The first operation performed for a gastrojejunal ulcer at the Mayo Clinic was in 1912. In 1948, Priestley and Gibson[1] reported results of a five- to 10-year follow-up of 103 patients who had had gastric resection for gastrojejunal ulcer; the ulcer had developed after gastroenterostomy had been carried out for a previous duodenal ulcer. Further surgical treatment was required in 5.8% of the patients because of secondary recurrent ulceration.

In 1960, Walters[2] reported a six- to 10-year follow-up study of patients who had gastrojejunal ulcer after gastroenterostomy. They found that gastric resection was superior to vagotomy in nine cases in which gastrojejunostomy had been performed initially and that vagotomy was more effective than re-resection of the stomach when the gastrojejunal ulcer developed after resection of a third to a half of the stomach at the first surgery.

In 1966 Wychulis et al.[3] reported the experience with 360 patients who were operated on for recurrent gastrojejunal ulcer between the years 1950 and 1960. The average interval between the initial operation and the symptoms of recurrent ulceration was 7.4 years after gastroenterostomy, 1.9 years after gastric resection, 1.7 years after gastroenterostomy and vagotomy, and 1.1 years after gastric resection and vagotomy. Surgical treatment varied according to the type of initial operation and the surgical findings. Average follow-up data of 7.9 years on 305 patients indicated that the results were excellent or very good in 259 (84.9%), unsatisfactory in 31 (10.2%), and poor in 15 (4.9%).

Our Series

Our series is comprised of 106 patients who were treated at the Mayo Clinic for gastrojejunal ulcer from 1961 through 1965. Included are those patients who had their second operation done at our clinic for peptic ulcer during this period. There was a minimum follow-up period of five years for all 106 patients.

The 106 patients included in the series had a surgically or roentgenographically demonstrable gastrojejunal ulcer.

Findings and Comment

Age

The average age of the 106 patients was 54.2 years, with a range of approximately 24 years.

Sex

Men outnumbered women by approximately four to one: 84 (79%) men to 22 (21%) women.

Location of the original ulcers

Ninety-two (87%) of the patients originally

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

had duodenal ulcers, six (6%) had gastric ulcers, and one (1%) had a combination of a duodenal and gastric ulcer. In seven patients, the location of the original ulcer was unknown.

Roentgenographic Findings

Of the 106 patients who underwent surgical procedures for gastrojejunal ulcer, 75 patients had preoperative Xrays of the upper gastrointestinal tract, 59 (78.6%) of these 75 had evidence of gastrojejunal ulcer on roentgenograms. This group included all patients whether their ulcer was on the gastric side, on the jejunal side of the anastomosis, or in the stoma. Ulcer could not be demonstrated by roentgenogram in 16 (21.4%). There was no record of roentgenograms having been done for 31 patients. The percentage of positive results (78.6%) by roentgen examination in our series is somewhat higher than that recorded by other authors. Although x-ray examination is less often an aid in diagnosing gastrojejunal ulcers than in diagnosing gastric or duodenal ulcers, the results are positive in more than 50% of the cases, and thus the x-ray examination has been worthwhile.

Gastric Acidity

Of the 106 patients, 53 had free acid before their second surgery, 16 patients did not, and 37 patients either had no determinations done or the results had not been recorded.

Time Interval to Recurrence after First Operation

Thirty patients who underwent gastroenterostomy had symptoms of recurrent ulcer an average of 152 months after operation, compared to 56 patients with Billroth II who had symptoms of recurrent ulcer an average of only 31 months postoperatively. The recurrence time was even less for patients who had vagotomy as part of the original procedure. For those who had vagotomy and gastroenterostomy initially, the average recurrence time was 43 months, compared to those who had Billroth II and vagotomy, for whom the recurrence was six months. However, there were only five patients in this group. For the 99 patients in whom the time interval was known, the average was 67.8 months between the initial surgery and the recurrence of ulcer symptoms.

Nature of Recurrent Symptoms after First Operation

Ninety-nine patients had one or more symptoms; 79 had recurrent epigastric pain, 50 had recurrent gastrointestinal bleeding, 26 had clinical evidence of gastrointestinal obstruction, five had symptoms related to a fistula, and seven had symptoms not clearly stated in the history.

Distribution of Patients and Average Months Between First and Second Operations

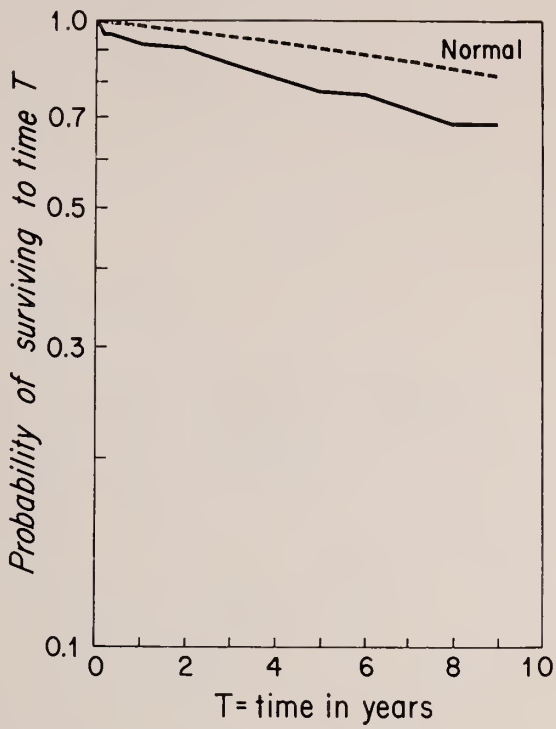
When gastroenterostomy was the initial operation, a Billroth II was the procedure most often done for the recurrence; next in frequency was a Billroth II with vagotomy. When Billroth II was the initial procedure, a gastric re-resection employing a Billroth II anastomosis with vagotomy was the most frequent second procedure; a gastric re-resection (Billroth II) was next frequent, and an abdominal vagotomy was third. Of all the procedures used for a second operation, the gastric re-resection with the Billroth II anastomosis and vagotomy and the gastric re-resection (Billroth II) were used equally often (22 cases). A gastric re-resection (Billroth II) was used in 17 cases, and abdominal vagotomy was used in 16 cases. Twenty-nine had procedures of another type.

Postoperative Course after Operation for Recurrent Ulcer

After the second operation, 82 patients had uneventful postoperative courses, two had recurrent gastrointestinal bleeding, one had obstruction, and 21 had miscellaneous complications; several patients had more than one complication.

Ulcer Condition after Surgery for Recurrent Ulcer

Of the 106 patients, 86 completed the part of the follow-up questionnaire that concerned the general effect of the second operation: 80 (93% of these) reported improvement and six (7%) noted no improvement. Because of the few patients in each surgical group, the percentage of improvement for each respective surgical procedure was not statistically significant. Of 81 patients who reported their health status, 57 (70%) said it was good or excellent and six (7%) said it was poor. Of 89 who reported regarding ulcers, 72 (81%) said that they had had no recurrence of ulcer symptoms, and 17 (19%) had had recurrence of one or more ulcer symptoms. Among the 17 patients with symptoms, eight had pain, four had vomiting, four had diarrhea, six had bleeding, and four had symptoms of another nature. An attempt was made to establish whether the recurrent symptoms were due to recurrent ulcer, the previous surgery, combined effect, or other causes. However, the evaluation was not valid or reliable enough to test for statistical significance.



For the 17 patients with symptoms, the average time from the second operation to the occurrence of the symptoms was 29 months, with a range

rom six months (Billroth I and vagotomy) to 61 nonths (gastric re-resection or Billroth II).

Seven of 87 patients (8%) each required a hird operation for peptic ulcer disease: two of 1 patients whose second operation was gastric e-resection (Billroth II) and vagotomy, two of 12 vho had had a Billroth II procedure, one of 15 vho had had gastric re-resection (Billroth II), one of three who had had gastric re-resection (Billroth) and vagotomy, and one of nine who had had a Billroth II and vagotomy. Nineteen patients did not report regarding further procedures.

At the end of the follow-up period, 30 patients were dead. Deaths were attributable to various causes, the most common being cirrhosis of the iver in seven cases and arteriosclerotic heart disease in six cases.

The five-year survival rate for patients with recurrent ulcer was 78%. This compares with an expected five-year survival rate of 90% for a comparable normal population (Figure). At nine years, the rates were 69% and 82% respectively. The survival curves are shown in the Figure.

Figure—Survival after second ulcer operation. Solid line represents experience in this series, broken line experience in normal population without recurrent ulcer.

Conclusions and Summary

A series of 106 patients with gastrojejunal ulcer were operated on between 1961 and 1965 at the Mayo Clinic. Follow-up data were available on all patients. The most frequently used second procedures were gastric re-resection (Billroth II) with vagotomy (22 cases), gastric resection (Billroth II) (22 cases), gastric re-resection (Billroth II) (17 cases), and abdominal vagotomy (16 cases). 24 patients had a procedure of another type. Fifty-seven of 81 patients who completed questionnaires (70%) reported that their health was good or excellent after the second operation. Eighty of the 86 patients (93%) noted improvement in their condition. Seven of 87 (8%) required a third surgical treatment. Secondary surgery for gastrojejunal ulcer following surgical treatment of duodenal or gastric ulcer must be tailored to fit the current pathological findings. The second operation is dictated also in part by the type of procedure done at the initial surgery. Generalizations cannot be made and the best surgical judgment has to be used based on the experience of the operating surgeon. The five-year survival rate for patients with recurrent ulcer disease was 78% compared to 90% in a comparable normal population group. The most common cause of death was cirrhosis of the liver.

Minnesota Medical Information Service

A new and exciting "on-line" information service is available free to Minnesota physicians. Called the Minnesota Medical Information Service (MMIS), the project is funded by Northlands Regional Medical Program and housed at the University of Minnesota.

Any Minnesota physician may call the information service 24 hours a day via a single toll-free telephone number given below.

Information Services Available

1. *Medical Library Service*—If a physician needs information from the current medical literature, he will be connected to a trained librarian at the University of Minnesota Bio-Medical Library. After learning the topic on which information is needed, the librarian will conduct a fast, on-line literature search using *MEDLINE,* a computer link to the National Library of Medicine in Washington. She will then describe the ten or so most recent articles published on the subject requested, make photocopies requested from the journals in the Bio-Medical Library, and have them in the mail to the physician the same day. The standard photocopy charge of ten cents per page will be imposed, plus one dollar for handling. There will be no charge to the physician for the literature search. This service is not meant to replace existing medical library services, but to provide such services if the librarian in the local hospital cannot do the search or does not have the journal requested. We hope, through this service, to serve the practicing doctors' information needs quickly and efficiently.

2. *Medical/Dental Specialty Advice*—If a physician has a clinical problem he needs help with, he may call MMIS and state his problem. MMIS maintains a list of specialists from the University full-time and clinical faculty, and the Mayo Clinic, and will have the next specialist "on call" return the call to the requesting physician promptly to provide that specialist-practitioner dialogue on demand. As with the library service, we do not wish to disturb any existing consultant relationships, only to provide help for a practitioner when he does not know who to call about a specific clinical problem.

3. *Dial Access Tapes*—Northlands Regional Medical Program has maintained a dial access tape service for years, connected to the University of Wisconsin. We have now moved the tape library to the University of Minnesota and provide these short (five minute) audio learning sessions on over 500 clinical topics. These are kept up to date and listed in a catalogue available from Mr. LeRoy Berglund, Northlands Regional Medical Program, 375 Jackson Street, St. Paul 55101. Simply give the MMIS operator the tape number you would like to hear, sit back and listen.

4. *Drug Information Service*—The Drug Information Center (DIC) is staffed by pharmacists from 8 a.m. to 5 p.m. Monday through Friday. During evening, night and weekend hours the health science students, who will be answering the MMIS telephones, will handle all calls to the DIC. If necessary, they will be assisted by an on-call pharmacist.

Types of questions that you may wish to direct to the DIC include the following:

1. Drug identification and availability—i.e. commercially available U.S. drugs, foreign drug products, and investigational drugs.
2. Therapeutic uses or doses for new and old drugs.
3. Therapeutic compatibility—i.e. drug interactions.
4. Pharmaceutical compatibility—i.e. I.V. incompatibilities.
5. Reports of side effects, contraindication and adverse reactions.
6. Biopharmaceutical information.

Calls regarding poison information should be directed to your nearest poison control center.

In summary, MMIS is designed to provide the practicing physician with medical information through audio tapes, through dialogue with specialists, through access to articles in the medical literature, and through drug information. All these services are available 24 hours a day to all physicians in Minnesota.

The telephone numbers to call are: *373-1855* for Minneapolis-St. Paul area, *1-800-552-7210* (toll free) for outstate area.

Winston R. Miller, M.D.
Director, Northlands Regional Medical Program

DYAZIDE®

Trademark

Each capsule contains 50 mg. of Dyrenium®
(brand of triamterene) and 25 mg. of hydrochlorothiazide.

CAN STOP POTASSIUM DEPLETION BEFORE IT STARTS

WITH NO SACRIFICE OF THIAZIDE EFFECTIVENESS

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

*Indications: Edema associated with congestive heart failure, cirrhosis of the liver, the nephrotic syndrome; steroid-induced and idiopathic edema; edema resistant to other diuretic therapy. Also, mild to moderate hypertension.

Contraindications: Pre-existing elevated serum potassium. Hypersensitivity to either component. Continued use in progressive renal or hepatic dysfunction or developing hyperkalemia.

Warnings: Do not use dietary potassium supplements or potassium salts unless hypokalemia develops or dietary potassium intake is markedly impaired. Enteric-coated potassium salts may cause small bowel stenosis with or without ulceration. Hyperkalemia (>5.4 mEq/L) has been reported in 4% of patients under 60 years, in 12% of patients over 60 years, and in less than 8% of patients overall. Rarely, cases have been associated with cardiac irregularities. Accordingly, check serum potassium during therapy, particularly in patients with suspected or confirmed renal insufficiency (e.g., elderly or diabetics). If hyperkalemia develops, substitute a thiazide alone. If spironolactone is used concomitantly with 'Dyazide', check serum potassium frequently—both can cause potassium retention and sometimes hyperkalemia. Two deaths have been reported in patients on such combined therapy (in one, recommended dosage was exceeded; in the other, serum electrolytes were not properly monitored). Observe patients on 'Dyazide' regularly for possible blood dyscrasias, liver damage or other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving Dyrenium (triamterene, SK&F). Rarely, leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with the thiazides. Watch for signs of impending coma in acutely ill cirrhotics. Thiazides are reported to cross the placental barrier and appear in breast milk. This may result in fetal or neonatal hyperbilirubinemia, thrombocytopenia, altered carbohydrate metabolism and possibly other adverse reactions that have occurred in the adult. When used during pregnancy or in women who might bear children, weigh potential benefits against possible hazards to fetus.

Precautions: Do periodic serum electrolyte and BUN determinations. Do periodic hematologic studies in cirrhotics with splenomegaly. Antihypertensive effects may be enhanced in postsympathectomy patients. The following may occur: hyperuricemia and gout, reversible nitrogen retention, decreasing alkali reserve with possible metabolic acidosis, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), digitalis intoxication (in hypokalemia). Use cautiously in surgical patients. Concomitant use with antihypertensive agents may result in an additive hypotensive effect.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis; rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting (may indicate electrolyte imbalance), diarrhea, constipation, other gastrointestinal disturbances. Rarely, necrotizing vasculitis, paresthesias, icterus, pancreatitis, and xanthopsia have occurred with thiazides alone.

Supplied: Bottles of 100 capsules.

IN EDEMA*—IN HYPERTENSION*

If you've seen one, have you really seen them all?

The following patient profiles represent typical clinical situations, but do not necessarily represent actual cases.

Age 22, previously normal me
with occasional menorrhagia
on a sequential O.C. for four m
Complains of heavy flow
occasional intracyclic bleedin
edema, tender swollen breast
Indicates estrogen excess
1st choice: Switch to a com
bination 50-mcg.-estrogen O C
(such as **Demulen**®).

Age 19, small breasts, minor hirsutism, oily hair and skin. History of metrorrhagia, skipped or scanty menses. New user.
Indicates androgenic excess or estrogen deficiency (fertility is suspect).
1st choice: An estrogen-dominant O.C. (such as **Enovid-E**®).

Age 25, average frame, poor complexion. No problem with menses, normal para 1. On a low-estrogen/high-progestogen O.C. for two years. Now complains of scanty flow, decreased libido, depression.
Indicates probable buildup of progestogen-related side effects.
1st choice: Switch to a center-spectrum O.C. with more estrogen, less progestational activity (such as **Ovulen**®).

Age 21, short, mammose, with normal menses, some acne. Was put on prenuptial regimen of 50-mcg.-estrogen/moderate-progestogen O.C. for two months. Now has increased acne.
Indicates metabolic production of androgen or relative estrogen deficiency
1st choice: Switch to a 100-mcg.-estrogen combination (such as **Enovid-E**® or a sequential).

Unmasked, physiologically and anatomically, they're not all the same. A basic difference lies in their hormone profiles. One may secrete too much estrogen, another not enough...or perhaps too much androgen; the vast majority would fit somewhere into the broad center spectrum.

Although the profiles described below may not be completely predictive, in optimal O.C. selection, the estrogen-progestogen activity ratio should be carefully matched to the patient profile. Searle offers you O.C.s in a range not only suitable for your patients in the balanced center spectrum, but also adaptable to the patient with another type of hormone profile.

Oral contraceptives are complex medications. Among the commonly reported adverse reactions are: intracycle bleeding, fluid retention, tender or swollen breasts, exacerbation of acne condition, changes in libido, amenorrhea while on medication and upon discontinuance, nausea, leg cramps, headaches, weight gain. Therefore, after reference to the prescribing information, oral contraceptives should be prescribed with care.

*Note: In some patients any level of exogenous estrogen or progestogen may produce symptoms of excess hormone activity.

, tall, slender, athletic,
at chest. On a progestogen-
ant 50-mcg.-estrogen O.C.
current trichomoniasis
onilia.
cales estrogen deficiency and
s of progestogen in current O.C.
choice: Switch to a com-
on pill with 100 mcg.
en and less progestational
y (such as **Enovid-E**® or
n or a sequential).

Age 23, "Miss America" figure, previously normal menses, healthy skin and hair. On a 50-mcg.-estrogen pill for four months. Complains of intracyclic bleeding.
Indicates probable need for more estrogen.
1st choice: Switch to a center-spectrum O.C. with more estrogen and moderate progestogen dominance (such as **Ovulen**®).

Age 21, college senior, average build. On highly progestogen-dominant/low-dose-estrogen O.C. for six months. Now complains of amenorrhea, between-cycle headaches, weight gain.
Indicates probable progestogen excess.
1st choice: Switch to a center-spectrum pill (such as **Ovulen**®).

Age 27, slightly overweight, multiparous. Nausea with all three pregnancies and with a sequential O.C. three years ago. Has pre-menstrual fluid retention and leg cramps.
Indicates probable excess of estrogen.
1st choice: A 50-mcg.-estrogen/progestogen-dominant pill (such as **Demulen**®).

Ovulen® a balanced center-spectrum O.C. for most

Each white tablet contains ethynodiol diacetate 1 mg./mestranol 0.1 mg.

Demulen® a moderately progestogen-dominant O.C. for many

Each white tablet contains ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.

Both Ovulen and Demulen are available in 21- and 28-pill schedules.

SEARLE Products of SEARLE & CO.

a brief summary
prescribing information,
ease see next page.

a family of O.C. products to help you match the right pill to the right patient

Ovulen®

Each white tablet contains
ethynodiol diacetate 1 mg /mestranol 0 1 mg.

Demulen®

Each white tablet contains
ethynodiol diacetate 1 mg /ethinyl estradiol 50 mcg.

Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.

Actions – Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note – Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication – Ovulen and Demulen are indicated for oral contraception.

Contraindications – Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings – The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain[1-3] leading to this conclusion, and one[4] in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll[3] was about sevenfold, while Sartwell and associates[4] in the United States found a relative risk of 4 4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions – The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any pos influence of prolonged Ovulen or Demulen therapy on pituitary, ovarian, adr hepatic or uterine function awaits further study. A decrease in glucose toler has been observed in a significant percentage of patients on oral contra tives. The mechanism of this decrease is obscure. For this reason, diabet tients should be carefully observed while receiving Ovulen or Demulen the The age of the patient constitutes no absolute limiting factor, although treatn with Ovulen or Demulen may mask the onset of the climacteric. The patho should be advised of Ovulen or Demulen therapy when relevant specimens submitted. Susceptible women may experience an increase in blood pres following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives – A statistically significant association has been demonstrated betw use of oral contraceptives and the following serious adverse reactions: thron phlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, such a relat ship has been neither confirmed nor refuted for the following serious adve reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abd inal cramps and bloating), breakthrough bleeding, spotting, change in menst flow, amenorrhea during and after treatment, edema, chloasma or melas breast changes (tenderness, enlargement and secretion), change in we (increase or decrease), changes in cervical erosion and cervical secretions, s pression of lactation when given immediately post partum, cholestatic jaund migraine, rash (allergic), rise in blood pressure in susceptible individuals i mental depression.

Although the following adverse reactions have been reported in users oral contraceptives, an association has been neither confirmed nor refut anovulation post treatment, premenstrual-like syndrome, changes in libi changes in appetite, cystitis-like syndrome, headache, nervousness, d ness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforr erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral cont ceptives: hepatic function: increased sulfobromophthalein retention and oth tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and thyroid function: increase in PBI and butanol extractable protein bound iodi and decrease in T^3 uptake values; metyrapone test and pregnanediol det mination.

Editorials

Mayo Medical School: "What's Past Is Prologue"

EARLY IN THE YEAR 1968, the staff of the Division of Education, Mayo Foundation, was charged by the Trustees of Mayo Foundation to prepare a model of a medical school in the Mayo institutional setting. This model was presented to the Board in July. There followed four months of intensive analysis and discussion in which a host of committees and individual members of our staff were involved. Each departmental chairman was requested to submit to the Board of Trustees a report on the viewpoint of his departmental members with respect to the medical school. At the meeting of the Trustees on November 25, the Trustees received the reports of the departmental chairmen, of the Board of Governors of Mayo Clinic, and of the Commission of University Presidents, an advisory council developed jointly under the auspices of the Regents of the University of Minnesota and the Trustees of Mayo Foundation. The Trustees then took the following actions:

Resolved, That the Board of Trustees favors the development of undergraduate medical education as a part of the activities of Mayo Foundation. This development is to be conditioned upon its financing, with minor exceptions, by funds to be raised from public and private sources not now part of Mayo Foundation's income and capital flow.

Resolved further, That there be an exploration in depth of a suitable academic affiliation, with reasonable autonomy, for the Mayo Medical School, or alternatively, of its independence as a recognized degree granting institution.

During 1969 discussion proceeded with the University of Minnesota on extension of our affiliation agreement to include a Mayo medical school. On March 13, 1970, the Regents of the University and the Trustees of Mayo Foundation entered into such an affiliation. I shall quote five paragraphs from the section of the agreement entitled "General Principles of Affiliation":

I. The University of Minnesota through its College of Medical Sciences and Mayo Foundation are the two senior and major Minnesota institutions in the field of medical service, medical education and medical research. As such, they bear a heavy and shared leadership responsibility to the State of Minnesota and to a substantial region beyond the boundaries of the State in the important area of health.

II. The University is a public institution established by the Constitution of the State, enjoying a preponderance of public with a measure of private support. Mayo Foundation, including its proposed medical school, exists as a private trust for public purposes enjoying a preponderance of private but a measure of public support. Each institution identifies its public character by vesting ultimate authority and responsibility in Regents or Trustees, respectively, so selected as to insure appropriate representation of the public.

III. There is envisioned an equal partnership of responsible, mature, independent institutions, capable (granted vision, foresight, and mutual understanding) of a synergistic combination of strengths not now wholly congruent.

IV. There is mutual recognition of the irreducible residuals of institutional independence, embedded in the organic law of each, which cannot be eliminated, but which need not be barriers to men of good will working for the public good.

V. The two institutions agree to build upon the mutually profitable association of more than fifty years in graduate medical education. The aim is an ever broader, more fruitful collaboration.

Mayo Medical School thus functions as an educational unit of the University of Minnesota owned and operated by Mayo Foundation. Its dean is nominated by the Trustees of Mayo Foundation to

he President of the University of Minnesota and s Regents. Its students will be granted their M.D. degree on recommendation of the Faculty nd Dean of Mayo Medical School to the Univerity President and Regents. Mayo Graduate School of Medicine will continue to be a part of he Graduate School of the University of Minneota.

To foster application of the general principles enumerated in the Affiliation Agreement, a University of Minnesota-Mayo Foundation Liaison Committee was established. That Committee is composed of representatives from the Board of Regents of the University and the Board of Trustees, Mayo Foundation, as well as two senior administrative officers of each institution.

With the academic affiliation agreed on, we were able to concentrate on other aspects of planning for the school. We faced major tasks in designing curriculum, developing faculty, and raising money to pay for our proposed programs. We have attempted to design a curriculum based on established institutional strengths as these are represented in faculty, facilities, and institutional traditions and goals. We have been determined to maintain "one house." If Mayo Medical School is to fulfill the high purposes envisioned for it, then it must be an expression of the finest resources and purposes of the existing Mayo institutions, not a new and foreign program standing discrete and apart from all that has gone before and proceeds today. We believe we have set up an academic program which reflects these clearly defined purposes. Moreover, we shall continue to recruit our staff and faculty as always we have: to total institutional purposes. We shall not have a faculty specific to "the medical school."

As regards payment of the costs, the Commission of University Presidents had advised that when we could see our way through the first 10 years of operation, we should proceed. We calculated as carefully as we could the *incremental* costs of an undergraduate educational program in the Mayo setting. These summated to 33 million dollars, over 80% of which figure is in support of faculty time and overhead on that time. We turned to three principal sources for enlistment of this financial support. These were as follows:

We requested of the state of Minnesota capitation support of our students at the rate of $8,000 per student per year. The 1971 session of the Minnesota Legislature approved this support of Minnesota residents only for the biennium beginning July 1, 1971. We have indicated to the legislators that continuation of support at this level is essential to the stable fiscal operation of Mayo Medical School.

We worked with other institutions and commissions in fostering federal legislation designed to increase markedly the support of undergraduate medical education. Legislation authorizing substantial increase in federal support, primarily on a capitation basis, was enacted by the Congress. Unfortunately, corresponding appropriations approximated only 65%. Bringing appropriations to the level of authorizations is an objective for fiscal year 1973 and worthy of broad support from the medical profession.

Through the Mayo Development Program initiated in 1965, we approached private sources of philanthropy—foundations, corporations, and private donors—and they have responded generously. We achieved our goal of securing (from these private donors) something in excess of one third of our anticipated costs of operating the medical school for its initial 10 years.

On November 12, 1971, the Board of Trustees of Mayo Foundation authorized opening Mayo Medical School in September 1972. Forty students compose the first class, 90% of whom will be residents of Minnesota. We sought to identify and recruit students of diverse talents and professional goals for that first class, as we shall for succeeding classes, and we shall foster that diversity through curricular design, student counselling, and preceptorial assignments. As funds from our Development Program increase, we shall take a larger proportion of our students from states other than Minnesota, probably by increasing total size of the class and not by reducing the number of Minnesotans appointed.

Faculty to execute the curriculum has been selected from among our clinical and research staff. During this first curricular year, we shall try to facilitate the student's transition from the formal academic programs of his college education into an environment of learning wherein one day he will come to realize that the patient is his greatest teacher. From the beginning, we shall seek to foster patterns of behavior which will permit the student to garner data efficiently from diverse sources and by various means—above all else, from the patient himself. These patterns, once established, will serve him well through that

if skin is infected, or open to infection...

choose the topical that gives your patient–

- broad antibacterial activity against susceptible skin invaders
- low allergenic risk—prompt clinical response

Special Petrolatum Base Neosporin® Ointment

(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand Polymyxin B Sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical aftercare, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

lifelong process of professional growth and learning to which he must devote himself if he is to serve his patients well and provide them the finest medical care. We believe our institutional resources are well adapted to this academic mission.

We embark today on a new and challenging journey. But we intend that this altered course shall fault no old commitment nor sacrifice worthy traditions long revered.

We proceed into these new responsibilities in such humility of spirit as becomes our inexperience. But we are sustained by that confidence which belongs to those who have met past challenges and have overcome.

Mayo Medical School, Rochester, Minnesota.

Raymond D. Pruitt, M.D.
Dean

The University of Minnesota Welcomes the Mayo Medical School

The opening of the Mayo Medical School runs current with a time in which health is one of our most pressing national issues. The people of America are becoming increasingly aware of health care as a basic human right. The traditional health care delivery system of the country has been quite a good one in past years. However, it is now being required to exercise a new ingenuity in order to cope with changing patterns of population distribution which have left some population groups, such as those in rural and urban areas, relatively isolated from adequate medical services.

In order to overcome some of these problems, the academic community with the help of organized professional groups, have recognized that there are at least three major components which require particular focus. First, *enough* of all kinds of health professionals must be trained. Then there must be the development of innovative health care delivery programs that effectively utilize the skills of health professionals and which make use of modern technology for efficiency, while maintaining a strong humanistic element for the comfort of the patient. It is not enough to develop new programs. The programs must be evaluated and properly accredited to maintain standards, and they must merit the acceptance of both professionals and patients they involve. Finally we need supportive research programs which probe and attempt to solve difficult health problems which plague the population.

Minnesota health practitioners and health institutions have been responsive in all three of these areas. They are internationally known for specialized medical care, for training programs and basic research, and some have provided national leadership in the exploration of alternative health care systems. Our state legislators, who consistently have desired a high level of health for their people, have encouraged and supported these efforts.

Although Minnesota has as few problems in the area of health as any state, we have shared a problem common to many other states: that pertaining to the distribution and types of services offered by medical professionals—i.e., the need for greater availability of primary care.

The University of Minnesota is working hard to help increase primary medical care where it is needed in the State. Twin Cities Medical School admissions have increased from 162 in 1969 to 239 in 1973. In addition each year approximately 30 students transfer from the Universities of North and South Dakota for their junior and senior years. Additionally about 24 students will enter the new two year medical program in Duluth beginning this academic year.

Another major step which directs itself to the challenge of primary care in Minnesota is the development of the undergraduate medical education program at the new Mayo Medical School, the curriculum of which places an emphasis on primary practice.

On March 13, 1970, at a meeting of the University Regents and the Mayo Board of Trustees, Chairman of the Mayo Board of Governors Dr. Emmerson Ward and University President Malcolm Moos signed an affiliation agreement for Mayo Medical School. This act added another dimension to an affiliation between the two institutions which has been in effect since 1915.

The existence of the Mayo Medical School especially complements the traditionally outstanding work of the Mayo Clinic and is a strong demonstration of the sensitivity of those of the Mayo complex to the health needs of the State. The new School will admit 40 students this year (36 of whom are residents of Minnesota). This means that by the mid 70's, the medical schools of Minnesota will graduate over 325 students per year!

It gives me great pleasure to offer best wishes and to pledge the support and cooperation of the University of Minnesota Health Sciences to Mayo Medical School. Furthermore, we all join in congratulations to Dr. Ward; to Mr. Atherton Bean, Chairman of the Mayo Board of Trustees; to Dr. Raymond Pruitt, Dean of the Mayo Medical School; and to the distinguished faculty and all other supporters of the School. We heartily welcome the establishment of another fine medical school for Minnesota.

Lyle A. French, M.D.
Vice President for Health Sciences Affairs
University of Minnesota

The Mayo Medical School

THIS ISSUE OF MINNESOTA MEDICINE is devoted to an event of great significance in Minnesota, the opening of the Mayo Medical School in Rochester. At the turn of the century several medical schools existed in the state but these were all absorbed into the University before 1910. For some six decades then there was only one.

Now there are two and soon three with the opening of the Duluth school. There can be no question that all are urgently needed; all graduates of Minnesota schools will immediately find full employment for their needed skills.

Rochester with the Mayo Clinic is the natural choice for a medical school. Its faculty, both in clinical medicine and in basic science, matches that of the great schools throughout the country.

As Lyle French points out, the several schools in Minnesota will work together with the University of Minnesota co-ordinating all. The Mayo Medical School will enhance the name of its founders, of Rochester and the State. The world of medicine will know the impact of this significant event. We look forward to the contributions that will be made by the graduates of the new school in Rochester. The contributors to this issue, guest edited by Raymond Pruitt, Dean of the Mayo Medical School, are all members of his faculty. We thank them not only for the October issue but also for their massive support to this journal in previous contributions. We confidently expect the pages of MINNESOTA MEDICINE in the future will expose some of the work of this institution, and undoubtedly, manuscripts of graduates of the new medical school.

Reuben Berman, M.D.
Editor

Dr. Henry Stanley Plummer

THE MEDICAL PROFESSION is indebted to Henry Plummer on many scores. His contributions to our knowledge of thyroid disease are well known and widely appreciated. Of comparable importance was his early work concerning esophageal disease and the management of difficult esophageal problems, particularly stricture.

Perhaps Henry Plummer's most notable and lasting contributions were his remarkably innovative approaches to the effective organization of medical practice. His appreciation that the physical layout of a building and the development of a proper record system could materially affect the quality and effectiveness of medical practice was nearly unique in his time. The group practice of medicine, which continues to grow in importance, is deeply indebted to his early insights.

Keys* has given us a graphic picture of the genius of Henry Plummer and has told us of his great human warmth. It is timely that Dr. Keys has reminded us once again of this fine clinician, this imaginative organizer, this "medical Thomas Jefferson" of whom Minnesota can be so justly proud.

Is Dementia Treatable?

One in ten Americans is 65 years old or more. With more elderly in our midst, stereotypes of the aged as enfeebled, helpless, and infirm must come under our increasing purview if we are to avoid the gerontophobic conclusion that old age itself is a disease. It is not, but it may be accompanied by various disorders such as dementia. As Sandok* noted in this issue, some forms of dementia are definitely treatable, leading to an improvement in the quality of life experienced. In the functional disorders, for example, the value of psychotherapy for some of the elderly is not to be underestimated,[1] medication and electroshock therapy also proving quite useful and desirable. Clinical approaches to dementia must also include paying attention to those emotionally involved with the elderly, such as relatives whose ability to cope may be strengthened by family conference and other measures. Not everyone who appears demented is elderly. Facing the problem of dementia, treatable and untreatable, may not only challenge diagnostic acumen, but also ripen the ethical and philosophical fruits of practice.

Referred Otalgia

Harold Wolff stated in his classical treatise on head pain that "the ear is unique in that there is no structure in the body of comparable size that is supplied by sensory nerves from so many neural segments."[4] The ear receives sensory fibers from cranial nerves five, seven, nine, and ten and from cervical roots two and three. The ear may be the site of referred pain resulting from pathologic states in areas remote from it.

There is some variation in the contributions of the individual nerves. In addition a number of investigators have demonstrated overlap in the central connections of the nerves supplying the ear in the brain stem and cervical cord. For example stimulation of the upper cervical roots may result in pain experienced in the ear.[2] Consequently localization of the specific nerve involved in ear pain is very difficult.

Kern* has sharply etched the dilemma facing the physician whose examination of the patient with painful ear fails to disclose local pathology in the ear.[1] His discussion is quite helpful in detailing the more important conditions referring pain to the ear and the alternative sites to be checked. It is particularly important as Kern points out to search for occult malignancy in the nasopharynx and larynx. Dental disease often refers pain to the area of the ear and the initial dental evaluation may not disclose the source so that persistence may be required.

The fifth cranial nerve also supplies the intracranial dura and tentorium. Wirth and Van Buren have demonstrated pain referred to the ear from stimulation of the dura.[3] Intracranial malignant, inflammatory, and vascular processes must also be considered as causes of referred otalgia although precise localization of the source may not be possible.

Dr. O. T. Clagett, a Mayo Clinic surgeon, has been named 1972 winner of the Presidential Citation of the American College of Chest Physicians, one of the five highest honors given by the college. He will be honored at a convocation Oct. 23 in Denver for his "achievements in and contributions" to the field of chest surgery.

Count all the ways you can enjoy *the Statesman's Club*

- Free use of private clubroom and lounge facilities in downtown Minneapolis and St. Paul. Meet your friends. Spend a quiet hour. Relax with current periodicals and newspapers.
- Or use the TV room.
- Free coffee, cookies and soft drinks.
- Hostesses on duty to serve you.
- Check your packages free.
- Free meeting room for up to 50 people, by reservation.
- Plan a vacation to far corners of the world with travel arrangements at low group rates.
- Free traveler's checks.
- Free Stateman's Club luggage tags.
- Special rate on Hertz rental cars.
- Local, one-day group outings at cost.
- A private office for your use, by reservation.
- A conference room for your use, by reservation.
- Free use of adding machine and typewriter.
- Free copying service. (Limit of 10 copies in any month.)
- Free use of office message center.
- Free notary public service.
- Free quarterly news letter.
- Free use of Statesman's Club facilities in other major cities when traveling.

That all counts up to a mighty big reason for joining the Statesman's Club at Twin City Federal. A minimum savings account of $5[illegible] qualifies you for membership ($20,000 for a corporation.)

A corporation membership provides you and other designated members of your company with excellent business facilities including attractive conference rooms and an auditorium that seats 50.

Be a Statesman. You'll enjoy.

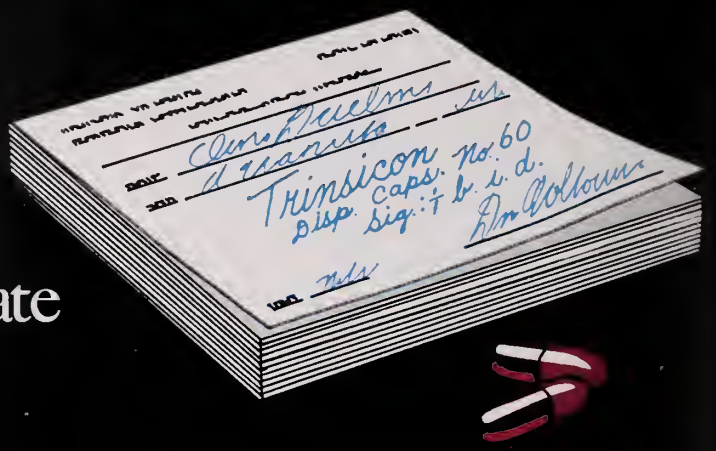
Iron therapy for anemia is almost as old as history itself

Celsus's empirical use of iron

Aulus Cornelius Celsus recommended an unusual form of iron therapy for the treatment of enlarged spleens—the oral administration of water that blacksmiths had used for dousing white-hot iron.



For more modern anemia therapy

Trinsicon®

Hematinic Concentrate with Intrinsic Factor

(See reverse side for prescribing information.)

Trinsicon®
Hematinic Concentrate with Intrinsic Factor

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	240 mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin	7.5 mcg.
(The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	
Iron, Elemental (as Ferrous Fumarate)	110 mg.
Ascorbic Acid (Vitamin C)	75 mg.
Folic Acid	0.5 mg.

Indications: Trinsicon is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia. Therapeutic quantities of hematopoietic factors that are known to be important are present in the recommended daily dose.

Vitamin B_{12} with Intrinsic Factor—When secretion of intrinsic factor in gastric juice is inadequate or absent (e.g., in Addisonian pernicious anemia or after gastrectomy), vitamin B_{12} in physiological doses is absorbed poorly, if at all. The resulting deficiency of vitamin B_{12} leads to the clinical manifestations of pernicious anemia. Similar megaloblastic anemias may develop in fish tapeworm (*Diphyllobothrium latum*) infection or after a surgically created small-bowel blind loop; in these situations, treatment requires freeing the host of the parasites or bacteria which appear to compete for the available vitamin B_{12}. Strict vegetarianism and malabsorption syndromes may also lead to vitamin B_{12} deficiency. In the latter case, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient.

Potency of intrinsic factor concentrates is determined physiologically, i.e., by their use in patients with pernicious anemia. The liver-stomach concentrate with intrinsic factor and the vitamin B_{12} contained in two Pulvules Trinsicon provide 1½ times the minimum amount of therapeutic agent which, when given daily in an uncomplicated case of pernicious anemia, will produce a satisfactory reticulocyte response and relief of anemia and symptoms.

Concentrates of intrinsic factor derived from hog gastric, pyloric, and duodenal mucosa have been used successfully in patients who lack intrinsic factor. For example, Fouts *et al.* maintained patients with pernicious anemia in clinical remission with oral therapy (liver extracts or intrinsic factor concentrate with vitamin B_{12}) for as long as twenty-nine years.

After total gastrectomy, Ficarra found multifactor preparations taken orally to be "just as effective in maintaining blood levels as any medication that has to be administered parenterally." His study was based on twenty-four patients who had survived for five years after total gastrectomy for cancer and who had been taking two Pulvules Trinsicon daily.

Folic Acid—Folic acid deficiency is the immediate cause of most, if not all, cases of nutritional megaloblastic anemia and of the megaloblastic anemias of pregnancy and infancy; usually, it is also at least partially responsible for the megaloblastic anemias of malabsorption syndromes, e.g., tropical and nontropical sprue.

It is apparent that in vitamin B_{12} deficiency (e.g., pernicious anemia), lack of this vitamin results in impaired utilization of folic acid. There are other evidences of the close folic acid-vitamin B_{12} interrelationship: (1) B_{12} influences the storage, absorption, and utilization of folic acid, and (2), as a deficiency of B_{12} progresses, the requirement for folic acid increases. However, folic acid does not change the requirement for vitamin B_{12}.

Iron—A very common anemia is that due to iron deficiency. In most cases, the response to iron salts is prompt, safe, and predictable. Within limits, the response is quicker and more certain to large doses of iron than to small doses.

Each Pulvule Trinsicon furnishes 110 mg. of elemental iron (as ferrous fumarate) to provide a maximum response.

Ascorbic Acid—Vitamin C plays a role in anemia therapy. It augments the conversion of folic acid to its active form, folinic acid. In addition, ascorbic acid promotes the reduction of ferric iron in food to the more readily absorbed ferrous form. Severe and prolonged vitamin C deficiency is associated with an anemia which is usually hypochromic but occasionally megaloblastic in type.

Contraindications and Precautions: Anemia is a manifestation that requires appropriate investigation to determine its cause or causes.

Folic acid *alone* is unwarranted in the treatment of pure vitamin-B_{12}-deficiency states, such as pernicious anemia. Indeed, the use of folic acid in large doses in pernicious anemia without adequate vitamin B_{12} may result in hematologic remission but neurological progression.

As with all preparations containing intrinsic factor, resistance may develop in some cases of pernicious anemia to the potentiation of absorption of physiological doses of vitamin B_{12}. If resistance occurs, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient. No single regimen fits all cases, and the status of the patient observed in follow-up is the final criterion for adequacy of therapy. Periodic clinical and laboratory studies are considered essential and are recommended.

In extremely rare instances, skin rash suggesting allergy has been noted following the oral administration of liver-stomach material. Allergic sensitization has been reported following both oral and parenteral administration of folic acid.

Hemochromatosis and hemosiderosis are contraindications to iron therapy.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastrointestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects in the iron-sensitive patient.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500 and in Identi-Dose® (unit dose medication, Lilly) in boxes of 100.

Case Report

Werner's Syndrome
Case Report of A Variant

CLAYTON REYNOLDS, M.D., J. DESMOND, O'DUFFY, M.B., B.Ch. AND
W. MITCHELL SAMS, JR., M.D.

In 1904, WERNER[1] DESCRIBED four cases of a peculiar disorder he called "cataract in connection with scleroderma." Thirty years later, Oppenheimer and Kugel[2] reviewed his cases, added two new ones, and described the characteristics of the full syndrome as follows: (1) shortness of stature with characteristic habitus of thin extremities and normal trunk, (2) premature baldness, (3) premature graying of hair, (4) atrophy of skin beginning in the second decade, (5) acral skin ulcers, (6) juvenile cataracts, (7) hypogonadism, (8) tendency to mild diabetes mellitus, (9) calcification of blood vessels, (10) osteoporosis with periarticular calcification, and (11) tendency to occur in siblings.

We present here the history, physical findings, and laboratory data of a patient representing a variant of this syndrome in that the first three features were absent. The distinction between Werner's syndrome and progressive systemic sclerosis is emphasized.

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

Report of Case

History

An unmarried 43-year-old man presented at the Mayo Clinic in October 1970 because of dysphagia and heartburn. He had been born in Ontario, Canada, to a 19-year-old mother of Scottish origin and a 21-year-old father of Irish descent. There was no known consanguinity and the family history, traced by the patient for four generations, was negative for cataracts and diabetes mellitus; graying of the hair and baldness began in one brother at age 25 years. Pregnancy and delivery were uneventful, and the patient was considered normal at birth. At age four years, bilateral nerve deafness followed whooping cough. A photograph taken at that time and examined by us showed no remarkable features but one at age six showed wrinkling of the face, especially around the mouth; this was the first evidence of abnormality.

The patient had a normal active childhood until, in his early teens, episodes of fever and arthritis in the knees, ankles, and elbows occurred. At age 16, he noted that the skin of his arms, fingers, and feet was tight and dry. Contractures of the fingers and toes resulted in ulcerations at bony prominences. Puberty did not occur; the genitalia remained small, pubic and axillary hair growth was scanty, and his voice was high-pitched. By the late teens, his eyes had become prominent, his nose

Fig. 1—Appearance of patient on admission. Proptosis, wrinkled perioral skin, sparse beard, and aphakic pupils.

pinched, and his face wrinkled, all combining to make him appear prematurely old.

His growth did not stop prematurely; in fact, he kept growing until age 25, at which time he first shaved. Over the ensuing years he attended the Toronto General Hospital for intensive rehabilitation and multiple surgical procedures. The first operation was at age 29 when he had bilateral cataract removal for decreasing vision and a tarsorrhaphy for proptosis. Ulcers of the feet required skin grafting, and the toe contractures were so severe that bilateral midtarsal amputation became necessary.

At age 39, amputation of the right third and fourth distal and middle phalanges and fusion of the right fifth proximal and distal interphalangeal joints were done to relieve flexion contractures. There was progressive tightening of the skin on the legs, arms, hands, and feet. Raynaud's phenomenon did not occur. During the prolonged hospital stay necessary for these procedures, numerous urinary tract infections occurred.

At age 41, flexion contractures of the right metacarpophalangeal joints were treated by the insertion of Silastic prostheses. Metabolic studies at that time revealed mild adult-type diabetes mellitus.

While in the hospital, he developed symptoms of

Fig. 2—Roentgenogram with barium, showing diaphragmatic hernia.

esophagitis and had a gastrointestinal hemorrhage requiring blood transfusion. A roentgenographic study with barium revealed a diaphragmatic hernia. His referral was prompted by a second major gastrointestinal hemorrhage in September 1970, with weight loss, dysphagia, and persistent esophagitis uncontrolled by antacids.

Physical Examination

The patient had the general appearance of an emaciated, wrinkle-faced man (Figure 1) who walked as if on stilts, because of previous midfoot amputations. His blood pressure was 130/70 mm Hg, pulse rate 76/min, weight 113 pounds, and height 70 inches. There was no loss or graying of the scalp hair. The skin around the mouth was wrinkled, the nose was pinched, and he was unable to open his mouth widely. His voice was child-like. He wore well-fitting upper dentures; the lower teeth were carious. Severe sensorineural hearing loss was partly corrected by a hearing aid. His eyes were prominent; the pupils were irregular and did not react to light. There were well-healed scars of lid surgery. Each cornea showed vascularized scarring inferiorly; on the left this had the appearance of a 4-mm pterygium. Funduscopic findings were normal. The thyroid appeared normal.

The skin of the lower extremities was thin, bound down, and sclerotic over bony prominences. Telangiectasia was not present. Over the trunk the skin exhibited a mottled, reticular hypopigmentation but with normal texture. There was marked hyperpigmentation of the coccygeal and ischial tuberosities. Both anterior thighs and calves showed scars from graft donor sites. No synovitis was noted.

The thin extremities contrasted sharply with the normal-sized trunk. Elbow and finger contractures were present. Range of motion of all joints of the extremities was limited; for example, the knees could be flexed only 70° and the metacarpophalangeal joints, only 45°. The right third and fourth middle and distal phalanges were missing.

There was no gynecomastia. Pubic and axillary hair were absent. The penis was small; the left testicle was absent and the right was atrophic, and the prostate was small. Markedly atrophic, but not myotonic, muscles were found in all extremities. The patient was cooperative, of normal intelligence, and able to carry out all usual activities of self-care. Results of cardiovascular and abdominal examinations were normal except for mild hepatomegaly and slight epigastric tenderness to deep palpation. Temporal, occipital, femoral, and popliteal pulsations were normal. The posterior tibial arteries were not felt, perhaps because the tightness and induration of the skin obscured their pulsations.

Laboratory Data

Routine. The following were normal or negative: electrocardiogram, hemoglobin concentration, leukocyte total and differential counts, platelet count, stool for occult blood, serum iron, serum uric acid, urine specific gravity, and urine sugar. The urine showed mild proteinuria (2+), one leukocyte and two erythrocytes per high-power field, and an occasional hyaline cast. Blood urea was slightly increased, 56 mg/100 ml (normal, 17 to 51). Creatinine clearance was diminished to 55 ml/min/1.73

n² (normal, 120 to 130). The erythrocyte sedimentation ate was 60 mm in one hour (Westergren).

Hematologic Studies. A peripheral blood smear showed nacrocytosis suggestive of vitamin B_{12} or folate deficiency; the serum B_{12} level was 238 pg/ml (normal, 60 to 850), and serum folate was 1.4 ng/ml (normal, to 16).

Metabolic Studies: The urinary screen for amino acids nd homogentisic acid was normal. Serum lipids were: holesterol, 332 mg/100 ml (normal, 150 to 300); triglycerides, 99 mg/100 ml (normal, <150); and phospholipids, 321 mg/100 ml (normal, 180 to 320). The ollowing were normal or negative: serum calcium, phosphorus, and alkaline phosphatase, buccal smear for Barr odies, karyotype, fasting and two-hour postprandial lood glucose, serum thyroxine, ^{131}I uptake, thyroid scan, serum luteinizing hormone, and response to ACTH stimulation. The 24-hour urinary excretion of 17-ketogenic steroids was 9.2 mg (normal, four to 14), of 17-ketosteroids 3.2 mg (normal, six to 21), and of pituitary gonadotropin six rat units (normal, four to 20); plasma testosterone was 64 ng/100 ml (normal, 250 to 1,200).

Immunologic Studies. Plasma proteins were: albumin, 3.8 gm/100 ml; α_1-globulin, 0.56; α_2-globulin, 2.1; β-globulin, 1.1; and γ-globulin, 1.0. The LE cell, rheumatoid factor, VDRL serologic, antinuclear antibody, and antithyroid antibody tests were negative.

Gastrointestinal Studies. Esophageal motility was normal. Results of gastric juice analysis (12-hour specimen) were: volume, 275 ml; pH 2.0; titratable acid, 91 mEq/liter; and output, 7.5 mEq/hr. Liver function tests gave the following data: prothrombin time, 18 seconds (normal, 17 to 19); sulfobromophthalein retention, 0% in 45 minutes (normal, <5%); serum glutamic-oxaloacetic transaminase, 22 units/liter (normal, <24); serum lactic dehydrogenase, 77 units/liter (normal, <127); and serum creatine phosphokinase, 28 units/liter (normal, <71).

Roentgenographic Studies. Roentgenograms of the extremities showed marked loss of soft tissue, osteoporosis with old bilateral metacarpal fractures, metacarpophalangeal joint prostheses in the third, fourth, and fifth digits of the right hand, and contracture deformity of both hands. The abdominal aorta and pelvic arteries were calcified. The upper gastrointestinal series (Figure 2) revealed a short esophagus with diaphragmatic hernia and evidence of gastroesophageal reflux. The chest and head were normal.

Skin Biopsy

Histological examination (Figure 3 *left*) showed atrophic skin. The epidermis showed moderate flattening of the rete ridges with hyperkeratosis. In sections stained with hematoxylin and eosin, the hair follicles and sweat glands were normal in appearance and number for the skin of the arm. The collagen fibers were fine and frayed. There were blue-stained fibers intermixed between the collagen fibers, particularly in the upper portion of the dermis. Elastic tissue stains revealed a marked increase in thick and clumped elastic fibers in the upper third of the dermis. The elastic fibers in the deeper dermis appeared normal. All of these findings are those of actinic or solar elastosis resulting from chronic sun exposure in

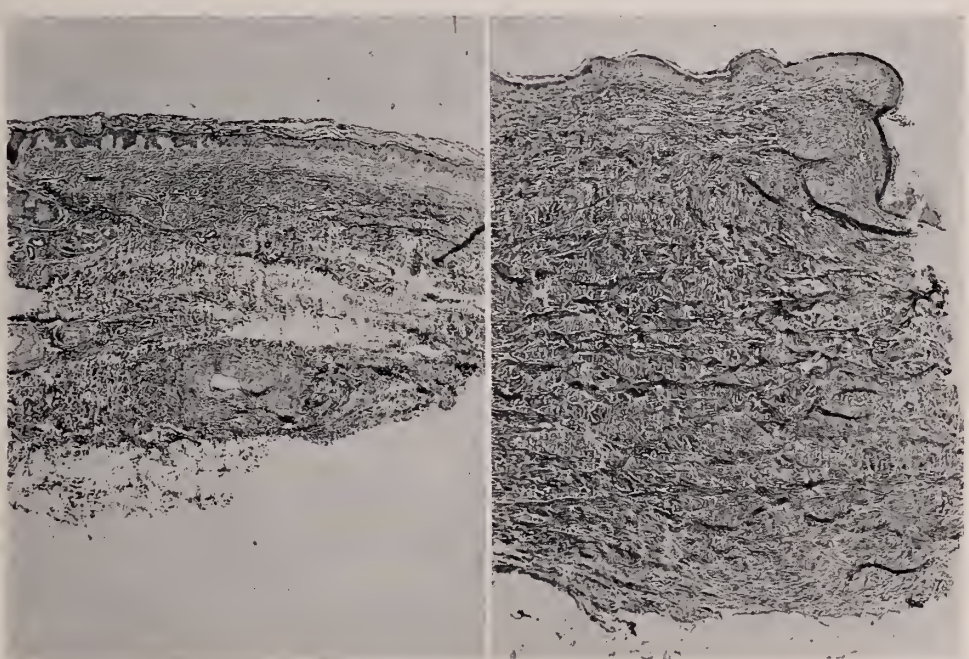

Fig. 3—Skin biopsies. (Hematoxylin and eosin; x 35.) *Left,* From forearm of our patient, showing atrophy of dermis with normal appendages. *Right,* From forearm of patient with typical case of scleroderma, showing thickening of dermis with atrophy of appendages.

an individual of fair complexion.

A skin biopsy from a similar site in a typical case of scleroderma (Figure 3 *right*) showed a marked decrease in appendageal structures, particularly hair follicles and sweat glands. The sweat glands that remained were small and located within the mid-dermis rather than in the lower dermis as is usual. The entire dermis was greatly thickened for this part of the body, and the individual collagen fibers were thickened, had a homogeneous appearance, and had lost much of their striations.

A quick-frozen biopsy specimen from our patient, sectioned on a cryostat and stained with fluorescein-conjugated anti-human immunoglobulins, failed to demonstrate in vivo fixed antibodies for basement membrane, intercellular space, or blood vessels.

Hospital Course

Two esophageal dilatations resulted in relief of the dysphagia but worsening of the esophagitis. Because the latter was uncontrolled by full doses of antacids, the patient underwent repair of the hiatal hernia. The surgical procedure included a transabdominal vagotomy, pyloroplasty, and repair of the sliding esophageal hiatal hernia combined with a Nissen fundoplication and posterior gastropexy. An episode of postoperative atelectasis with retention of tracheobronchial secretions responded to conservative measures. Staphylococcal sep cemia developed but responded to large doses antibiotics. Bilateral keratitis due to incomple closures of lids during sleep was considerably in proved by blepharorrhaphy. He was dismissed the 21st postoperative day with no esophage symptoms.

Discussion

The differential diagnosis included Werner syndrome (heredofamilial dermatosis with sk ulcers), Rothmund's syndrome (heredofamilial de matosis with telangiectasia), scleroderma (pr gressive systemic sclerosis), and the Hutchinso Gilford syndrome. The Table lists the features Werner's syndrome, the present case, and Rotl mund's syndrome.

We suggest this case is a variant of Werner syndrome. Evidence for there being *form frustes* of this disease has in the past centered o the findings of diabetes mellitus[3] and prematu graying of the hair[4] in relatives of patients wit the fully developed syndrome. Until the preci etiology or biochemical lesion can be establishe patients with minor variations from the full syr drome may be regarded as having the basic di ease. The facial features in this case, as well a the areas of skin involved in the atrophic proces are strikingly similar to those in a case reporte by Shelby and Vaughn[5] as juvenile Werner's syr drome. Those authors pointed out that moder

TABLE
Contrastng Features of Werner's Syndrome, Present Case, and Rothmund's Syndrome

Features	Werner's	Present case	Rothmund's
Familial occurrence	Present	Absent	Absent
Skin changes	Tightening, hyperkeratosis, atrophy of skin & subcutaneous tissue: ulcers of extremities; no telangiectasis	Same	Venous distention & telangiectasis with pigmentation; no tightening or hyperkeratosis
Age, onset of skin changes	20-30 yr	6 yr	Few months
Trophic ulcers	Prominent	Prominent	Absent
Muscular development	Poor, atrophic	Poor, atrophic	Better
Cataracts	Early adult life	20 yr	Early childhood
Vocal cords	Epithelial changes	Not examined	Normal
Sexual deve'opment	Absent	Absent	Normal
Hair	Premature graying, baldness	Normal	Normal
Short stature	Present	Absent	Absent
Arteriosclerosis	Prominent	Present, not prominent	Absent
Osteoporosis	Prominent	Prominent	Absent
Diabetes mellitus	Often present	Present	Absent
Thyroid dysfunction	Variably present	Absent	Absent
Proptosis	Present	Present	Absent
Soft-tissue calcification	Present	Present	Absent

drugs and treatment may alter the findings and course of a disease, thus changing it from its classic description. This comment applies to our patient who has had prolonged and intensive medical care in the form of ophthalmic, orthopedic, and gastric surgery, antibiotics, and hormones.

Scleroderma

Scleroderma (progressive systemic sclerosis) is excluded for many reasons. In this disease the skin on the face is thick and bound down and loses its wrinkles. In our patient, the skin was atrophic with increased wrinkling, a finding completely out of keeping with scleroderma. Histologically, the two are distinct. In our patient there was no fibrosis or sclerosis of collagen fibers but there was loss of rete pegs and papillary projections and fragmentation of elastic tissue which was decreased in amount. The use of the term "scleroderma-like" should be discouraged; it is unfortunate that Werner used it in his original description[1] and writers have continued to use it even after the publication of Thannhauser's review.[6]

Although childhood scleroderma is rare, it does occur and persist into adulthood. The absence of Raynaud's phenomenon and of esophageal motility abnormality strongly contradicts the diagnosis of progressive systemic sclerosis, especially after so many years of skin involvement. The difficult problem of an esophageal hernia with severe reflux esophagitis presented by this patient has not previously been reported in connection with Werner's syndrome. The absence of a motility abnormality in the esophagus makes it unlikely that shortening of the esophagus by a sclerodermatous process is responsible. Possibly, the short esophagus is a congenital abnormality; its appearance in this patient may be a chance occurrence.

Rothmund's Syndrome

Rothmund's syndrome is excluded in this case by the fact that the skin lesions did not develop in the first few months of life, ulcerations appeared, and the skin was mostly involved over the distal extremities. Telangiectasia, a prominent feature of Rothmund's syndrome, was not present, but atrophy and tautness of the skin were. Atrophy of extremities, osteoporosis, diabetes, and arteriosclerosis are not found in Rothmund's syndrome but were present in our case. The age at which cataracts were first noted is more in keeping with Werner's than with Rothmund's syndrome.

Because our patient presented with skin ulcers and cataracts, this case does not fit the description of the Hutchinson-Gilford syndrome. In addition, the evidence of premature aging did not develop in our patient at as early an age.

Hypogonadism

The hypogonadism in this patient has features of both of the usual categories of hypergonadotropism and hypogonadotropism, since the urinary excretion of pituitary FSH was low normal in association with an atrophic testicle on one side and no testicle on the other. One would expect high urinary gonadotropin excretion in primary testicular failure. The best evidence of gonadal failure is not the 24-hour urinary 17-ketosteroid value, which can be accounted for on the basis of chronic debilitation, but the low level of plasma testosterone.

In diseases in which the etiology is established, as in homocystinuria,[7] the clinical picture need not be uniform from one patient to another in order to make the diagnosis. If multiple defects are responsible for Werner's syndrome, it would be even more likely that features would be variable. Variability in inheritance is recognized as sporadic cases have been reported.[8] Our case may be a sporadic one, the only evidence of a familial tendency being early graying and baldness in an older brother.

In gram-negative sepsis..

**Due to susceptible organisms*

Schering

The antibiotic of first resort...

In suspected or documented gram-negative sepsis, GARAMYCIN Injectable may be considered as initial therapy.

- Effectiveness against the nosocomial problem pathogens of the 1970's
- Proven clinical effectiveness
- Risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended
- Effective against pathogens resistant to many commonly used antibiotics
- Versatility and convenience of administration

Garamycin®

brand of gentamicin sulfate injection

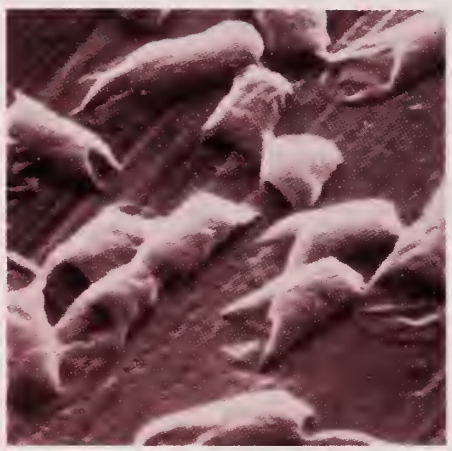
injectable

I.M./I.V.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

See Clinical Considerations section which follows...

The antibiotic to start with...



*In suspected or documented gram-negative sepsis due to susceptible organisms, GARAMYCIN Injectable may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important concepts contained in the Warning Box below.

An indispensable spectrum for today[1-3]

GARAMYCIN Injectable offers a high probability of effectiveness against virtually all of the gram-negative pathogens which are a growing cause of clinical concern. GARAMYCIN Injectable has also demonstrated striking activity against *Proteus* species, both indole-positive and indole-negative.[2]

Proven clinical efficacy[1,4-13]

GARAMYCIN Injectable may be lifesaving in septicemia . . . may give a dramatic response in wounds and burns complicated by sepsis. GARAMYCIN Injectable has also demonstrated outstanding results in serious gram-negative infections other than sepsis, such as serious respiratory infections and selected urinary tract infections. To date, GARAMYCIN Injectable has been the subject of more than 1,500 published papers and 12 international symposia.

Note: The photomicrographs of gram-negative organisms reproduced here were obtained by a relatively new process employing a scanning beam electron microscope. The pathogens represented are *Klebsiella pneumoniae, Escherichia coli,* and *Proteus mirabilis.* The colors shown here are an artist's representation. The magnification is 10,000X.

WARNING: Patients treated wit GARAMYCIN Injectable should be d close clinical observation because t potential toxicity associated with e use of this drug.

Ototoxicity, both vestibular an auditory, can occur in patients, p those with pre-existing renal dam e treated with GARAMYCIN Injectal , usually for longer periods or with hi doses than recommended.

GARAMYCIN Injectable is poten l

The antibiotic to stay with*

Schering

A high degree of sensitivity maintained[14-16]

Bacterial resistance to GARAMYCIN Injectable has not been a problem to date. In the laboratory, resistance has been demonstrated to develop slowly in stepwise fashion. No one-step mutations to high resistance have been reported. One investigator noted: "In the experience so far with [gentamicin], which is 7 or 8 years, in centers where it's been restricted to parenteral use, resistance has not appreciably changed."[14] Another authority "...found very little emergence of resistance" during eight years of use.[15]

In a survey of published studies on resistance to gentamicin, Weinstein and co-workers[16] report little change in bacterial sensitivity since 1963 in the percentage of sensitive strains. *In vitro* sensitivity was determined in all cases by the tube-dilution method.

Relatively low incidence of adverse reactions[3,14,17]

As with certain other aminoglycoside antibiotics, ototoxicity (primarily vestibular with gentamicin) and potential nephrotoxicity are risks of therapy.

Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy.

In contrast to kanamycin, neomycin, and streptomycin, which primarily cause deafness or difficulties in the auditory end organs of the eighth nerve, gentamicin primarily causes labyrinthian dysfunction.[14] This dysfunction, manifested by dizziness (not deafness) has, in most cases, been transitory.

As to nephrotoxicity, according to Finland,[3] "as in the case of kanamycin, the nephrotoxicity was found to be largely 'potential,' and very little if any has been encountered except with obviously excessive doses or in patients with already damaged kidneys."

Garamycin®
brand of gentamicin sulfate injection

injectable

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

rotoxic, and this should be kept in l when it is used in patients with xisting renal impairment.
onitoring of renal and eighth nerve tion is recommended during therapy itients with known impairment of l function. This testing is also mmended in patients with normal l function at onset of therapy who lop evidence of nitrogen retention easing BUN, NPN, creatinine or ria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

Usage in Pregnancy: Safety for use in pregnancy has not been established.

See Clinical Considerations section which follows...

When preculture signs point to gram-negative sepsis...

Garamycin® Injectable
brand of gentamicin sulfate U.S.P., injection 40 mg./cc.
Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin
For Parenteral Administration

WARNING: Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause toxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

INDICATIONS GARAMYCIN Injectable is indicated, with due regard for relative toxicity of antibiotics, in the treatment of serious infections caused by susceptible strains of the following microorganisms:

Pseudomonas aeruginosa, Proteus species (indole-positive and indole-negative), **Escherichia coli** and **Klebsiella-Enterobacter-Serratia** species.

Clinical studies have shown GARAMYCIN Injectable to be effective in septicemia and serious infections of the central nervous system (meningitis), urinary tract, respiratory tract, gastrointestinal tract, skin and soft tissue (including burns).

Bacteriologic tests to determine the causative organisms and their susceptibility to gentamicin should be performed.

Bacterial resistance to gentamicin develops slowly in stepwise fashion; there have been no one-step mutations to high resistance.

In suspected or documented gram-negative sepsis, GARAMYCIN may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important additional concepts contained in the "Warning Box." In the neonate with suspected sepsis or staphylococcal pneumonia, a penicillin type drug is usually indicated as concomitant antimicrobial therapy.

GARAMYCIN Injectable has been shown to be effective in serious staphylococcal infections. It may be considered in those infections when penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

CONTRAINDICATIONS A history of hypersensitivity to gentamicin is a contraindication to its use.

WARNINGS (See "Warning Box.")

PRECAUTIONS Neuromuscular blockade and respiratory paralysis have been reported in the cat receiving high doses (40 mg./kg.) of gentamicin. The possibility of these phenomena occurring in man should be considered if gentamicin is administered to patients receiving neuromuscular blocking agents such as succinylcholine and tubocurarine.

Treatment with gentamicin may result in overgrowth of nonsusceptible organisms. If this occurs, appropriate therapy is indicated.

ADVERSE REACTIONS

Nephrotoxicity: Adverse renal effects, as demonstrated by rising BUN, NPN, serum creatinine and oliguria, have been reported. They occur more frequently in patients with a history of renal impairment treated with larger than recommended dosage.

Neurotoxicity: Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss.

Numbness, skin tingling, muscle twitching, and convulsions have also been reported.

Note: The risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

Other reported adverse reactions, possibly related to gentamicin, include increased serum transaminase (SGOT, SGPT), increased serum bilirubin, transient hepatomegaly, decreased serum calcium; splenomegaly, anemia, increased and decreased reticulocyte counts, granulocytopenia, thrombocytopenia, purpura; fever, rash, itching, urticaria, generalized burning, joint pain, laryngeal edema; nausea, vomiting, headache, increased salivation, lethargy and decreased appetite, weight loss, pulmonary fibrosis, hypotension and hypertension.

DOSAGE AND ADMINISTRATION GARAMYCIN Injectable may be given intramuscularly or intravenously.

For Intramuscular Administration:

PATIENTS WITH NORMAL RENAL FUNCTION*

Adults: The recommended dosage for GARAMYCIN Injectable for patients with serious infections and normal renal function is 3 mg./kg./day, administered in three equal doses every 8 hours.

For patients weighing over 60 kg. (132 lb.), the usual dosage is 120 mg. (2 cc.) three times daily. For patients weighing 60 kg. (132 lb.) or less, the usual dose is 60 mg. (1.5 cc.) three times daily.

In patients with life-threatening infections, dosages up to 5 mg./kg./day may be administered in three or four equal doses. This dosage should be reduced to 3 mg./kg./day as soon as clinically indicated.

*In children and infants, the newborn, and patients with impaired renal function, dosage must be adjusted in accordance with instructions set forth in the Package Insert.

For Intravenous Administration:

The intravenous administration of GARAMYCIN Injectable is recommended in those circumstances when the intramuscular route is not available (e.g., patients in shock, with hematologic disorders, with severe burns or with reduced muscle mass).

For intravenous administration, in adults, a single dose of GARAMYCIN Injectable may be diluted in 100 or 200 cc. of sterile normal saline or a sterile solution of dextrose 5% in water; in infants and children the volume of diluent should be less. The concentration of gentamicin in solution, in both instances should normally not exceed 1 mg./cc. (0.1%). The solution is infused over a period of 1 to 2 hours.

The recommended dose for intravenous administration is identical to that recommended for intramuscular use.

GARAMYCIN Injectable should not be physically pre-mixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

HOW SUPPLIED GARAMYCIN Injectable, 40 mg. per cc., 2 cc. multiple dose vials for parenteral administration.

Also available, GARAMYCIN Pediatric Injectable, 10 mg. per cc., cc multiple-dose vials for parenteral administration.

Special Article

The Eye and Adverse Drug Effects

Some Selected Considerations

DENNIS M. ROBERTSON, M.D.

Numerous drugs have been implicated as causes of adverse reactions of the eye. In many instances reports of toxic reactions are isolated testimonials for which the likelihood of a cause-and-effect relationship is remote. In other instances undesirable side effects have been definitely established and can be linked directly to a specific drug. Whereas some side effects are serious, occasionally leading to permanent visual impairment or prompting emergency surgical treatment, others are relatively minor and accordingly generate little concern. While physicians may be aware of many of the ocular side effects induced by certain systemic drugs, the nonophthalmologist may be unaware of some of the serious systemic effects induced by topical ophthalmic preparations. It is important for the physician to recognize, for instance, not only that chloroquine may cause progressive pigmentary degeneration of the retina and blindness but also that certain topical antiglaucoma medications may decrease blood cholinesterases, a factor of concern when succinylcholine is considered with general anesthesia (anesthetic deaths have been noted in three cases in which topical diisofluorophosphate was used to treat glaucoma).[1]

This report reviews some selected considerations of toxicology of drugs as they relate to the eye. In general each drug will be considered relative to its local effect on the eye, its general effects from systemic absorption through the conjunctiva, and its adverse ocular effects when used systemically. A comprehensive review may be found in Grant's book, "Toxicology of the Eye."[2]

Drugs Which May Adversely Affect Intraocular Tension

Anticholinergic Drugs (Cycloplegics and Mydriatics)

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
Presented in part at the meeting of the Minnesota State Medical Association, Rochester, May 18, 1972.

Topical-Local Effect.—The topical use of mydriatics or cycloplegics can precipitate acute angle-closure glaucoma in predisposed eyes. Such eyes generally have shallow anterior chambers and narrow entrance angles and may show a sharp increase in intraocular tension if the iris crowds the angle and interferes with aqueous outflow. Eyes that have a tendency to develop angle-closure glaucoma may be suspect if gross examination utilizing a light directed across the iris suggests an unusually shallow anterior chamber. Most eyes, however, may be dilated with little concern because angle-closure provocation is uncommon.

In contrast with eyes predisposed to narrow-angle glaucoma, in some patients with open-angle glaucoma, topical cycloplegics (cyclopentolate, atropine, homatropine, and scopolamine) can cause a significant transient increase in intraocular pressure (greater than six mm). This effect is unassociated with angle closure and rarely requires specific treatment. The response is apparently related to an influence on the ciliary body. In one study,[3] 23% of the patients in whom 1% cyclopentolate was instilled topically were noted to have such a pressure increase. The effect was not seen with 10% phenylephrine, ½% tropicamide, or 5% eucatropine.

Prolonged topical use of atropine has been occasionally associated with local hypersensitivity reactions such as chemosis and lid edema.

Topical-Systemic Effects.—The parasympatholytic agents, when applied topically (atropine, homatropine, scopolamine, and cyclopentolate), may cause systemic anticholinergic intoxication with central nervous system symptoms; these include visual hallucinations, restlessness, ataxia, delusion, stupor, and coma. The symptoms, although generally dose-related, may appear as an idiosyncratic response also. In either situation, symptoms usually can be reversed by the use of 1 mg of physostigmine given intramuscularly, intra-

venously, or subcutaneously.[4,5]

Systemic Anticholinergic Drugs.—The United States Food and Drug Administration requires that all drugs with anticholinergic effects be accompanied by a warning against their use in patients with glaucoma, even though published evidence has been insufficient to establish whether these warnings are justified.[6]

Several clinical studies, both short-term and long-term, have been done to determine whether anticholinergic agents elevate intraocular pressure by pupillary dilation or by changes in aqueous dynamics.[7-10] One clinical experiment designed to study possible short-term effects on intraocular pressure by a systemically administered proprietary drug containing belladonna alkaloids showed that the drug did not produce adverse effects on intraocular tension or pupil size. The study included both normal volunteers and patients with glaucoma.[7] Lazenby et al.[9] studied the long-term effects of systemic atropine (0.6 mg twice a day for seven days) in patients with glaucoma. They noted little change in intraocular pressure unless the eyes were positive responders to topically applied cyclopentolate.

Because most parasympatholytic agents do not cause pupillary dilation when given systemically, angle-closure glaucoma would not be expected to be precipitated. Actually, few systemic drugs directly cause pupillary dilation, with the exception of scopolamine[11] and possibly *L*-dopa.[12] Most other drugs reported to cause mydriasis do so indirectly through central nervous system stimulation (marihuana, for example).[2]

Although the repeated administration of anticholinergic medications should be used cautiously in open-angle glaucoma, only a few patients will have significant adverse effects. Furthermore, patients with narrow angles or shallow anterior chambers do not present an inordinate risk.[10] Weekly tonometric evaluation during the first few weeks of systemic administration appears to be a practical method for determining possible adverse effects. If no pressure increase is noted at the end of this period, the drug probably could be continued indefinitely with little concern about ocular complications.

Agents Used in Anesthesia

Succinylcholine.—Succinylcholine administered intravenously can cause a precipitous increase in intraocular pressure by stimulating the extraocular muscles mediated via the tonic neuromuscular system. Accordingly, its use when eye is open can promote disastrous consequenc and is contraindicated under such conditions. A ditionally, succinylcholine can relax ocular accor modation secondary to relaxation of the cilia muscle.[13]

Halothane.—Anesthesia with halothane m produce a significant decrease in intraocular pr sure. This is an important consideration in t selection of an anesthetic during procedures d signed to determine the presence of congenit glaucoma in young children, because a spurio normal reading induced by halothane might le to an unnecessary delay in implementing therapy A review of 1,835 cases in which halotha anesthesia was used primarily in children reve l a decrease in intraocular tensions that was b lieved to be secondary to a decrease in bloo pressure.[15]

Ketamine.—In a series of patients who we six months to 77 years old, ketamine hydrochl ride administered intravenously produced an ave age increase of four mm Hg in intraocul tension.[16] Although ketamine is useful for certai ophthalmic procedures,[17] its short duration (ap proximately eight minutes) and its tendency t cause nystagmus and involuntary motor move ments near the beginning and again at the end o the anesthetic time are hazardous factors in i selection as an anesthetic agent.

Drugs Used to Treat Glaucoma

As a part of any presurgical medical evaluation the physician must determine whether a patient i receiving any topical ophthalmic treatment fo glaucoma; this is important because glaucom therapy ordinarily should continue uninterrupte during the preoperative and postoperative period Many patients will not volunteer this information and the physician must then ask specifically whether the patient is using eye medications.

Topical

Miotics.—Common symptoms of all miotics in clude brow and eye ache (related to ciliary spasm and blurring of vision, particularly in the presby opic or prepresbyopic patient. Some of the miotic have caused cysts at the pupillary margin of th iris; these cysts, which are most frequently see with the cholinesterase inhibitors, are generally reversible and may be prevented by adding phenyl ephrine to the solution.[2,18] Miotics also may cause iris congestion and a plasmoid aqueous high i protein concentration. A peculiar irreversible

band keratopathy recently has been observed as a beal complication associated with the prolonged se of some proprietary pilocarpines.[19] This ffect may not be related to the pilocarpine but ather to the preservatives that are added to the ehicle or to other factors.

Pilocarpine can cause such systemic symptoms s profuse diaphoresis, salivation, nausea, vomiting, gastrointestinal cramping, bronchiolar spasm, ulmonary edema, and symptoms suggestive of cute abdomen.[20] Such occurrences are uncommon and generally have been seen only in the ged who have exceeded the usual frequency of lrug instillation.

In addition to pilocarpine, irreversible cholinesterase inhibitors such as diisofluorophosphate and chothiopate iodide in concentrations of 0.08 to 0.25% are frequently used topically in the management of glaucoma. The production of lens opacities is a recently recognized local complication to add to other local effects such as iritis, accommodative spasm, and cysts of the pupillary margin.[21-23] Echothiopate iodide also has been incriminated in the development of retinal detachment.

Cholinesterase inhibitors can be absorbed in concentrations sufficient to reduce the levels of red blood cell and serum cholinesterases. Because succinylcholine is hydrolyzed by serum cholinesterase, succinylcholine probably should be excluded from the anesthetic regimen of patients who are receiving topical therapy with cholinesterase inhibitors, because prolonged apnea might occur.[24-27] Anesthetic deaths have been noted in three cases in which topical diisofluorophosphate was used to treat glaucoma.[1] (Diisofluorophosphate is also used in children for the treatment of accommodative esotropia—an important fact when surgery is being considered.) The dangers of using these drugs in patients under treatment for myasthenia also must be recognized.

Other systemic effects of the topical cholinesterase inhibitors include gastrointestinal symptoms, primarily cramping but occasionally diarrhea and nausea, increased salivary, bronchial, or lacrimal secretions, and rarely cardiovascular or neurologic disturbances.[24] Symptoms of acute abdomen have occasionally resulted in laparotomy.[28] These symptoms are uncommon if the equivalent dose of echothiopate iodide is 0.06% or less.[29]

Topical Epinephrine.—Local effects of topical epinephrine drops include burning and sometimes production of a beefy redness of the conjunctiva, as well as the deposition of melanin-like oxidation products of epinephrine; these deposits most commonly accumulate as discrete material in the conjunctiva but may also rarely cause diffuse corneal changes suggestive of malignant melanoma.[30] Unfortunately, eyes have been enucleated for this benign condition. Topical epinephrine also can cause systemic symptoms of sympathetic stimulation, including anxiety, palpitation, and other symptoms.[31] These drops should not be used in patients using monoamine oxidase inhibitors such as tranylcypromine (Parnate) because paradoxic systemic hypertension may result.[1]

Systemic Agents

Acetazolamide (Diamox) and related synthetics are occasionally used as systemic supplements to the topical therapeutic agents in the management of glaucoma. The prolonged use of these agents can cause paresthesias, gastrointestinal disturbances, loss of potassium, and occasional renal stone formation. Less likely known, however, is that acetazolamide may induce a reversible acute myopia as an ocular side effect.[2]

Steroids

Topical Steroid Therapy

Many ocular complications have been documented as a direct result of steroid therapy. The topical application of steroids potentiates fungus corneal ulcers and herpes simplex keratitis, elevates intraocular tensions in certain susceptible individuals causing on occasion irreversible glaucoma, induces the formation of cataracts, and retards local wound healing. Mitsui and Hanabusa[32] have shown the dramatic effect of topical steroid therapy on conjunctival flora. In their experiments, the recovery of fungus isolates changed from 0 to 50% after two weeks of topical steroid treatment. This may be a significant reason why steroids are increasingly incriminated in the rising incidence of keratomycoses.[33] Corneal ulcers seem to be adversely affected by steroids. Herpes simplex keratitis seems to be reactivated with greater than normal frequency after topical steroid use and once infection has been established, steroids significantly reduce resistance of the cornea to the virus.[34-37]

Topical steroids administered four times a day during a six-week period have caused a significant increase in intraocular pressure in more than 30%

of the normal population[38-40] (greater than 90% in a population with open-angle glaucoma[39]). In some instances, this has produced glaucomatous field defects[41] and irreversible glaucoma, though usually these effects are transient and the eye returns to pretreatment conditions when therapy is stopped. Although most of the studies of the induced-pressure increases have used 0.1% dexamethasone, other topical steroid preparations also can induce glaucoma; a notable exception may be medrysone.[42,43]

Topical steroids have retarded corneal wound healing under controlled experimental conditions. A recent report suggests that this retardation may be clinically significant. Stigmata of poor wound healing after cataract extraction included unintentional filtering blebs acquired frequently in the group of postcataract extraction eyes treated with topical steroids, compared to none in the control eyes treated with placebo drops.[44] Additionally, topical steroids may cause mydriasis and ptosis.[45]

Considering these many complications it is important that topical medications containing steroids be used only with specific indications and for a limited time.

Although no systemic symptoms have been related to the topical use of steroid agents, some systemic absorption appears to take place.

Nursall[46] showed a decrease in the quantity of circulating eosinophils after several days of topical therapy. Burch and Migeon[47] also demonstrated a decrease in the amount of urinary 17-ketosteroids collected during a 24-hour period after the topical application of dexamethasone.

Systemic Steroid Therapy

With the possible exception of activating herpes simplex and fungus keratitis, systemic steroids may cause all of the ocular complications previously noted. A recent study suggests that approximately 20% of patients who were given more than 15 mg of prednisolone each day (or its equivalent) for between two and eight years will develop complicated cataracts. Systemic steroid-induced glaucoma, though observed, is rare.[48]

Other Anti-inflammatory Agents

Chloroquine and Related Drugs

The retinopathy induced by chloroquine is dose-related. A total dose of as little as 100 gm may produce a retinopathy[49] that usually becomes manifest initially in the posterior pole where a delicate derangement of the pigment epithelium may be seen in the paramacular or parafoveal regions. These changes become more apparent with time and eventually may produce the bull's-eye appearance that is characteristic of advanced disease or, when more severe, a clinical appearance indistinguishable from advanced retinitis pigmenta.[49] After discontinuance of the use of the drug, the retinopathy may continue to worsen although this is not inevitable. In a long-term follow-up study, Carr et al.[50] found that of patients who had retinopathy when drug therapy was stopped, 12% improved, 64% showed no change and 24% became worse.

Early symptoms of chloroquine toxicity include difficulty in adjusting to bright lights and occasionally photophobia. These symptoms probably are related to the retinal toxicity.[51] The most common visual symptom noted by Percival and Behrman[52] was a transient aggravation of presbyopic symptoms, which was seen soon after initiation of therapy. In the early stages, central visual acuity may be normal in spite of a dense pericentral ring scotoma. Eventually, central vision may be lost, and with further retinal damage, nearly the entire visual field may be lost. Although alteration of red light thresholds was considered one of the first functional changes in chloroquine retinopathy,[53] it was not observed in all of Krill and associates'[54] patients.

No test will consistently provide unequivocal information of early retinal toxicity. Careful fundus examination at intervals after an initial pretreatment base-line evaluation still is the most practical method for the evaluation of potential retinal toxicity. In some instances, serial fundus photographs will be helpful, especially if some derangement of the pigment epithelium was present at the pretreatment examination. That objective serial fundus evaluation is important is supported by the observations of Nylander,[53] who found that 70% of patients with retinopathy had no subjective complaints. Nylander suggested that combining fundus examinations with perimetry and electroretinography would more consistently detect patients who had retinopathy. At this institution, serial fundus examination is frequently accompanied by fundus photography and fluorescein angiography.

Corneal changes are not uncommon in patients receiving chloroquine. These changes are functionally benign and disappear within months after therapy is discontinued.[54-55] The retinopathy may

appear without the keratopathy.[56] At this institution, we do not consider keratopathy a reason to discontinue chloroquine therapy.

Indomethacin

One author believed that indomethacin produced keratopathy reminiscent of the changes seen with chloroquine and physiologic alternations in the retina expressed as diminished voltage in the electroretinogram.[57] My colleagues and I have not recognized these complications.

Sodium Salicylate

High doses of sodium salicylate over short intervals may cause a temporary blindness, either complete or partial.[2]

Cardiovascular Drugs

Digitalis

Probably the most well known ocular effects of cardiovascular drugs are those related to digitalis toxicity. The reported incidence of ocular manifestations of digitalis toxicity has been estimated to be as high as 25%. These ocular manifestations may occur before other toxic symptoms.[61]

The most common ocular symptoms of digitalis toxicity are blurred vision and disturbed color vision. Both a transient and a permanent amblyopia accompanied by central scotomas have been described. Yellow vision is common, but green, blue, and red vision also have been noted. Occasionally, objects appear grayish or white as if covered with snow. Yellow vision, although classically suggestive of digitalis toxicity, also has been noted after chlorothiazide, marihuana, amyl nitrite, the sulfonamides, quinacrine, and streptomycin.[2,58] Experimental studies showed elevated dark-adaptation thresholds in normal human subjects who were given therapeutic nontoxic doses of digitalis.[59]

Parenterally administered digoxin lowers intraocular pressure as a consequence of a decrease in aqueous formation.[60] This effect is not sufficient to make digitalis practical in the management of glaucoma.[61]

Nitroglycerin and Amyl Nitrite

Nitroglycerin and amyl nitrite may cause a very brief increase in intraocular pressure in association with vasodilation. This is apparently the basis for occasional warnings against the use of nitroglycerin in the presence of glaucoma. Grant,[2] however, was unable to find any case reports in which nitroglycerin or amyl nitrite precipitated an attack of glaucoma.

Spironolactone

Spironolactone (Aldactone) is an aldosterone inhibitor that reduces aqueous flow, thought it is not an effective agent for the treatment of glaucoma.[1]

Antibiotics

Topical chloramphenicol used over prolonged intervals occasionally has caused hypoplasia of the bone marrow.[62] Topical neomycin, a common ophthalmic preparation, causes local hypersensitivity. Accordingly, it should not be commonly used as a first choice agent in the treatment of minor ophthalmic infections.

Among the systemic antibiotic agents, the sulfonamides probably have accounted for the greatest frequency of toxic ocular effects.[2] Toxic amblyopia secondary to sulfonamide therapy has been reported.[63] Grant[2] discussed the precipitation of an acute and completely reversible myopia by the use of sulfa drugs. The myopic change, which may amount to several diopters, is believed to be related to a change in the refractive property of the lens itself. The tetracyclines also have precipitated acute myopic change.[64]

Ethambutol, a drug used to treat tuberculosis, has caused involvement of the neuro-optic pathways. Its toxicity has been the subject of several experiments in primates.[65] Two patients receiving sparsomycin, an antibiotic used as a cancer chemotherapeutic agent, experienced blurred vision in association with ring scotomas and pigment changes in the macular region.[66]

Optic neuritis frequently has been associated with chloromycetin[2,67,68] and less frequently with isoniazid and streptomycin.[2]

Phenothiazine Derivatives

In 1960, Apt[69] summarized the complications of ocular side effects seen with the phenothiazine tranquilizers. Oculogyric crises have been seen with most of these drugs. Chlorpromazine was recognized as a cause of photosensitivity, and thioridazine was considered a cause of pigmentary degeneration of the macula, which was associated with visual loss, a constricted field, and abnormal dark adaptation. (Although thioridazine has produced retinal changes in dosages considered to be therapeutically safe, such occurrences are rare; the changes usually have occurred after prolonged use of higher dosages.)[70] In 1964, ocular pigmentation was noted in association with skin pigmentation after prolonged chlorpromazine therapy.[71] Ocular findings include pigmentation of

the lids (sometimes purplish in color) and exposed regions of the conjunctiva; golden brown granules in the epithelium and deep stroma of the cornea near the endothelium; and axial lens changes characterized by white or brownish yellow granules concentrated in the anterior subcapsular areas. In DeLong and associates'[72] review, no patient who received less than 500 gm experienced lens changes; corneal changes occurred only if patients received more than 100 gm; among patients who received more than 2,500 gm, 90% had lens changes.

Vision is not commonly affected by lens change, though a patient described by Trediei et al.[73] had a chlorpromazine-induced cataract that reduced vision. Additional less common complications include pigmentary clumping in the retina, retinal vessel attenuation, and disk pallor.[74] Apparently some of the deep corneal changes may regress slowly when the medication is discontinued.[75]

Gynecologic Drugs

Oral Contraceptives

Oral contraceptives have been associated with various ocular abnormalities. In one study,[76] however, the ocular findings of 212 patients using different oral contraceptive products were compared with ocular findings and symptoms in 50 normal control patients. No ocular disease or change was found in the treatment group that could not be expected in the random sample of the population. Walsh et al.[77] are maintaining a file on the reports of ophthalmic disease that has been suspected to be related to "the pill." An intolerance to contact lenses has occasionally occurred in patients who were previously wearing the contact lenses comfortably.[78,79]

Clomiphene

Clomiphene, an ovulatory-stimulating drug used in the treatment of female infertility, has produced transient scotoma in four of 58 patients. The retina was believed to be the site of toxicity.[80]

Topical Anesthetics

Topical anesthetics are commonly used in such routine procedures as removing foreign bodies and taking cultures for bacteria. These agents can delay healing of corneal abrasions.[81] Local anesthetics also have potent antibacterial and antifungal properties.[82-86] A recent prospective clinical study showed that bacterial recovery from the conjunctiva was significantly inhibited after instillation of commercially available proparacaine (Ophthaine).[87]

Miscellaneous

Ophthalmologists and neurologists are generally aware that many drugs (for example, opiates, barbiturates, diphenylhydantoin, ethyl alcohol) may induce ocular nystagmus.[88]

L-dopa may induce exaggerated symptoms of oculogyric crises in patients subject to these crises prior to therapy.[89] Additionally, *L*-dopa may produce a transient mydriasis that can be replaced by a significant and more chronic miosis.[90]

Miosis has been noted after opiates, reserpine and chloral hydrate, even in usual doses.[2] In addition to miosis, chloral hydrate may cause swelling of the lids and edema of the conjunctiva.[2]

A common manifestation of toxicity related to quinine, tobacco, and alcohol is amblyopia. Quinine poisoning is seen less now because the use of the drug has decreased. Nevertheless, toxic effects may occur in persons who are taking average doses, although it is more likely seen after an overdose. The effects range from a slight blur to complete blindness, which usually are partially reversible. Early ophthalmoscopic changes vary, but definite pallor of the optic nerve is seen later. The visual field defect in quinine amblyopia appears as a peripheral contraction.[91] Quinine also has been reported as a cause of iris atrophy.[92] Optic nerve hypoplasia after quinine ingestion has been noted.[93] Amblyopias of toxic origin are also associated with the long-continued use of tobacco or alcohol. Both eyes are usually affected with a characteristic centrocecal scotoma. Tobacco smoke from a pipe or in the form of cigars is generally necessary to produce this type of amblyopia,[94] but cigarette smoking has also caused this change. An interesting observation is reported by Parkinson,[95] who noted tobacco amblyopia primarily in older men who smoke cheap strong tobacco known as shag tobacco. After discontinuance of pipe smoking, visual improvement occurs. Some evidence shows that the effect of tobacco is ultimately related to a failure of detoxification of cyanide derived from tobacco smoke. Treatment with hydroxycobalamine may be effective in restoring vision.[96] This entire subject has recently been reviewed.[97] Alcohol amblyopia is probably a result of actual vitamin deficiency rather than a direct toxic effect of the drug.[94]

Vitamins A and D given in high doses have

produced adverse changes in the eye. Excessive vitamin D may produce calcific deposition in the cornea as a manifestation of hypercalcemia. This band keratopathy gradually disappears after cessation of the vitamin D.[2] Vitamin A in excess may produce loss of hair, which can include the eyelashes and eyebrows. A more significant problem perhaps is the development of increased intraocular pressure which causes papilledema. Four patients who had vitamin A intoxication with reversible papilledema were recently described.[98] Each patient was taking approximately 200,000 units of vitamin A each day for long periods, primarily for the treatment of acne. After cessation of the drug, the papilledema resolved very slowly.[98]

Cataracts have been associated with the use of several systemic drugs, some of which are no longer in use, such as triparanol.[99] Others, such as steroids, form a significant part of the therapeutic armamentarium of many practitioners. It has been suggested that dibromomannitol, an antimitotic agent that has been used in the treatment of chronic myelogenous leukemia, may cause posterior lens opacities.[100] Busulfan (Myleran) has been similarly incriminated.[2] Cataract production by these compounds is uncommon.

Prolonged use of eye drops of phenylmercuric nitrate was associated with a cataract that contained high concentrations of mercury.[101]

Signs of ocular toxicity were seen in 20 of 40 patients treated with vincristine sulfate for leukemia and other malignancies. These consisted of ocular muscle paresis and involvement of the fifth and the seventh nerve.[102]

The ocular abnormalities caused by thalidomide have been the subject of several reviews. Anophthalmia and colobomas were among the more severe defects. Paresis of the third and the sixth cranial nerve was not uncommon. Several children also had nasolacrimal duct obstructions.[103-105]

Visual disturbances have been related to the use of pheniprazine hydrochloride, a mono-amine oxidase inhibitor. This drug has been incriminated as a cause of optic neuritis.[106-108]

Transient visual hallucinations were noted in three patients treated with iminodibenzyl compounds (amitriptyline and imipramine) for depression.[109]

Reactions may follow intravenous fluorescein used as a diagnostic research tool in ophthalmology and occur in 0.6% of patients who undergo angiography. Although more than two thirds of the reactions were an allergic type characterized only by urticaria, more than one fourth were severe, often associated with a shock-like reaction.[110]

Summary

The ocular complications associated with topical and systemic medications are reviewed. Serious systemic manifestations may result from absorption of topically applied ophthalmic agents. The review considers anticholinergic agents, drugs used in the management of glaucoma, steroids and other anti-inflammatory medications, cardiovascular and gynecologic drugs, antibiotics, the phenothiazine derivatives, and others.

"The history of science, and in particular the history of medicine ... is ... the history of man's reactions to the truth, the history of the gradual revelation of truth, the history of the gradual liberation of our minds from darkness and prejudice."

– George Sarton, from "The History of Medicine Versus the History of Art"

Are combination drug products useful in treatment involving concomitant use of two or more drugs?

Opinion

Results of a questionnaire to 7,000 physicians:

62.9%
Believe combination drug products are useful.

13.8%
Do not believe combination drug products are useful.

Are combination drug products useful in treatment involving concomitant use of two or more drugs?

Opinion & Dialogue

and Dentistry

Obviously, many drugs are given concomitantly. Whether it makes sense to combine medications in one preparation, be it capsule, tablet, or liquid, is a question that can be answered only by examining the advantages and disadvantages in the individual case.

Among the advantages is, first of all, convenience. The more medications that are taken concurrently and the more complicated the directions, the less likely the patient is to take medications accurately. From the standpoint of convenience and accuracy, and economy as well, you can make an important case for putting medications together in one preparation, as long as they are compatible.

By the same token, when you prescribe a properly tested and rational combination, you should have less worry about pharmaceutical or pharmacological compatibility – and about reasonable dosage ratios as well. Compatibility of the formulation should be demonstrated in the laboratory and clinic before the product is available for prescription—which is more than can usually be said for the physician's own spontaneous creations. And, the dosage ratios employed in rational precompounded combinations are designed to meet the needs of substantial numbers of "typical" patients.

There is no doubt that many "atypical" patients are to be found, and for them the prefabricated combination must be rejected. But that hardly argues for eliminating rational combinations from the market. Think, for example, of the problems that would arise if the components of widely accepted combinations, like the oral contraceptives and the diuretic-antihypertensives, always had to be prescribed, purchased and ingested separately.

One disadvantage that comes to mind is some doctors' unawareness of the ingredients a given combination contains. For example, a doctor might know that a patient is allergic to aspirin but forget that a certain analgesic mixture, which he knows only by its trade name, contains aspirin. His prescription, then, causes considerable discomfort, to say the least. This problem is a function of physician education, rather than of combination therapy as such. Improving doctors' knowledge about all medicaments they prescribe is a problem that deserves tackling on its own.

Another accusation leveled at combination drugs is that they encourage sloppiness of diagnosis and treatment. In many cases, however, a combination may prove to be the most effective choice. A good example of the usefulness of combinations appears in a recent article in the *Journal of Chronic Diseases* on the efficacy and side effects of an antihypertensive containing three ingredients, in which the track records of the combination drug and the individual ingredients were compared. Interestingly enough, whether the drugs were given individually or together, incidence and severity of side effects were the same. But blood pressure control was invariably better when the drugs were taken in one combination tablet than when they were taken separately (in "titratable" dosage) or in two or three different tablets.

Deciding which combinations constitute rational therapy obviously leads to a discussion of who is to determine which should be used and which should not. Realistically, I think combinations should be evaluated somewhat differently if they are old and established or new and untried.

In today's regulatory atmosphere, there is no possibility of a new combination being put on the market without a substantial amount of acceptable evidence in the form of controlled trials that show it to be safe and efficacious. On the other hand, I believe a different set of standards should apply to combination preparations that have been around for a long time. In other words, physician acceptance over a long period should be given some weight as evidence of the efficacy and safety of these drugs.

The FDA, however, does not seem to share this attitude. It often requires, for these older products, controlled trials that will monopolize the time of already overtired investigators and cost a great deal of money. I wish we could agree on a "grandfather clause" approach to combinations that have been around for a number of years that have an apparently satisfactory track record.

For example, I think some of the antibiotic combinations that were taken off the market by the FDA performed quite well. I am thinking particularly of penicillin - streptomycin combinations that physicians—especially surgeons—were given by injection. This made for less discomfort for the patient, less demand on nurses' time, and fewer opportunities for medication errors. To take the combination preparation off the market doesn't seem to be good medicine, unless actual experience showed a great deal of harm from the injudicious (rather than the proper use) of the combination.

The point that should be emphasized is that both fixed combinations are both rational and irrational combinations. The real question is, who is to determine which is which? Obviously, the FDA must play a major role in determining this determination. In fact, I don't think we can avoid taking the ultimate responsibility, but it should enlist the help of consultant physicians and experts in assessing the evidence and in making the ultimate decision.

ake antibiotic mixtures,
source of much of the
icism generated against
combinations generally. Ohviously, no one should be exposed willy-nilly to the potential side effects of two or three antihiotics wben only one is needed. At the same time there are cases where it is prudent to prescrihe more than one. Tbe clinician is the judge in these circumstances, as he should be.

There is no clear definition of the word rational. Most persons, I suppose, would find it synonymous with reasonable, but in many circumstances it may best he defined as the opinion of those in power at the moment.

Other factors govern combination therapy, not the least of which has heen its broad use hy practicing physicians anxious to achieve convenience in prescribing, to reduce medication error, and to save money for their patients. Combinations clearly have met the test on all three counts.

I have heen impressed by studies showing that the rate of error climhs markedly with the number of medications to he taken, even with sophisticated patients. When medically justified, therefore, this factor alone supports the logic of comhination therapy.

The cost argument for combinations appears to he irrefutable. In 1971, R. A. Gosselin studied the 71 combination products (excluding oral contraceptives) among the 200 most prescribed drugs. The study found that if all 71 products were discontinued, and if each ingredient in these combinations were prescribed separately, the price of medicines to patients would jump by $443.2 million on a national hasis! At a time when the cost of medical care is under so much fire, it would be nonsensical to boost costs without clearly irrefutable medical reasons.

The part played by government on this question, of course, is fundamental. The FDA should play a role in determining which combinations are reasonable. That role, as defined by law and regulation, is to ensure that any medication on the market is safe and effective in line with its label claims. Certainly combinations are entitled to as much consideration as single entities—neither more nor less. So long as the addition of one drug to another does not make either less safe, or less effective, so long as they are compatihle in a formulation, we have a reasonable product. It makes no sense to recommend the use of two products for certain conditions and to deny their being comhined in a single form. An unhappy side effect of the problem concerns the efficacy panel discussions of many products suhmitted for review. The term "effective, but" has heen freely interpreted to mean "ineffective" in toto, regardless of the merit of the individual drugs. This interpretation has placed numerous useful comhination products in needless jeopardy.

In reading the actual reports of the review panels, it seems clear that some of the ratings were based less on scientific research and clinical observation than on the "informed" opinions of the panelists. These "informed" opinions were accepted at face value, while the "informed" opinions of others who had used the products were rejected. All of this put combination products into a sort of scientific never-never land.

It should be kept in mind by all, government as well as others involved in our health care system, that advances in therapy are seldom made in leaps and bounds hut rather by small painstaking steps—and that some of these steps have resulted from research in comhination drugs as well as with single entities. Given the near-infinite biologic variation in patient response, this is hardly surprising to clinicians. It should not be to regulatory agencies either.

In the end, the practicing physician is in the best position to decide if a particular comhination makes sense. Such a decision should not be made exclusively hy those whose responsibility for continuing clinical care is limited. Clinicians are the best judges of efficacy because the ultimate proof of any product's effectiveness is acceptance hy physicians who have observed its actions in patients over time. The corollary statement may be made about over-the-counter medicines, which would not long survive if they failed to afford the relief the user anticipates. That the antihistamine in a "cold" remedy may not *always* be necessary is no reason to proscribe the comhination generally.

Fracture Conference

Intercondylar T-Fractures

RICHARD S. BRYAN, M.D., JOHN A. WELSCH, M.D. AND
EINER W. JOHNSON, JR., M.D.

r. Richard S. Byran:

The intercondylar fracture, the so-called fracture or Y-fracture of the elbow, is a serious acture; but fortunately it is not common.

r. John A. Welsch:

The recent literature on intercondylar T-fractures of the humerus in adults reveals wide disagreement among orthopedists, first, in treatment nd second, in methods of evaluating end results.

Most of the vascular and neurogenic structures ourse through the anterior compartment of the bow, but the ulnar nerve courses around the edial epicondyle to the posterior compartment. ailure to restore the balance of muscle power, as ell as the articular surface, will lead to a poor nctional result. Normal range of motion of the lbow is flexion from 0 to 150° and pronation nd supination from 0 to 90°.

In a 12-year period, only 52 isolated T-condylar actures of the lower end of the humerus were een at the Massachusetts General Hospital. Few ases can be found in the recent literature. Riseorough and Radin[1] reported 29, Bickel and erry[2] included 17, and Miller[3] noted only 11 uch fractures.

The mechanism of this injury is a direct blow n the olecranon, which is then driven as a wedge pward between the humeral condyles. Typically, he fracture is due to a fall on the flexed elbow. n the cases reviewed, one such fracture occurred n a patient whose elbow was jutting from a car window and was struck by an object.

The treatment of the T-fracture can be divided nto three main types: (1) open method, which includes open reduction and anatomic assemblage of he fragments, with internal fixation and external support, (2) closed method, which includes manipulative reduction and plaster immobilization in a position of stability, or skeletal traction through an olecranon pin, or the collar-and-cuff or "bag of bones" treatment, and (3) combined method, which is an open reduction with internal fixation of the articular fragments, followed by closed manipulation of the supracondylar element of the fracture. Each treatment has advantages and disadvantages.

Closed manipulation followed by plaster immobilization frequently fails because most fractures of the elbow joint have very little natural stability and the maintenance of the reduction is uncertain. When stability is obtained in full extension, motion is not readily recovered at the elbow joint. Traction with or without manipulation is frequently unsuccessful because of the rotational pull on the condyles through the collateral ligaments and muscles. Early arthroplasty in a badly shattered elbow often gives a weak and unstable joint. Surgical intervention also carries the risk of infection and the possibility of periarticular adhesions.

Generally, the complications associated with T-fractures are loss of motion due to periarticular fibrosis, capsular contraction, bone block, or residual deformity; ulnar nerve palsy; instability; avascular necrosis of one of the fractured fragments; myositis ossificans; and skin necrosis.

In the surgical treatment of this type of fracture, the main objective is to achieve fixation so that early motion can be started. Two surgical approaches can be used. Bickel and Perry[2] and Miller[3] preferred the posterior approach as recommended by Speed[4] and Van Gorder.[5] Cassebaum[6] described a transolecranon approach. The main limitation of these approaches is the inability to visualize the vascular and neurogenic structures in the anterior compartment. In these approaches, the patient is placed prone, with his forearm hanging over an arm board. In the Van Gorder[5] approach a tongue of triceps is reflected, and the fractured fragments are visualized (Figure 1). The same approach can be used in the over-the-chest position. Various methods of internal fixation can be used: Kirschner wires (both plain and

threaded), screws, or "Y-plates." Basically, an attempt is made to restore the joint line first and then to fix the distal fragments to the humeral shaft.

Regardless of treatment, some restriction in motion can be expected in flexion and extension. Rarely is loss of pronation or supination a problem with this type of fracture.

Case Reports

Case 1

A 19-year-old girl fell from a motorboat and was struck by the propeller blade. Examination revealed a depressed open skull fracture and a laceration of the right elbow, with bone protruding. The initial roentgenogram showed a comminuted fracture of the condylar area of the right humerus (Figure 2). The initial treatment consisted of immediate craniotomy, with evacuation of a subdural hematoma, and debridement of the elbow fracture. The elbow fracture was then packed open, and the patient was placed in "side-arm" traction; three weeks later she was placed in a plaster cast. Six months after injury, she had flexion of 77 to 157° and full pronation and supination.

Case 2

A 19-year-old boy tripped and fell directly on his left elbow. The roentgenogram showed a displaced comminuted fracture of the left elbow in the supracondylar area (Figure 3 *A*). At surgery, the medial condyle was fixed internally to the lateral condyle and the remainder of the fracture was placed in traction. The ulnar nerve was translocated, and skeletal traction was applied. The

Fig. 2 (Case 1)—Intercondylar T-fracture. Initial roentgenograms. *(A)* Anteroposterior view. *(B)* Lateral view.

Fig. 3 (Case 2)—Intercondylar T-fracture. *(A)* Initial Anteroposterior view. *(B)* After surgery.

postsurgical roentgenograms show the medial fragment with a screw and the arm in skeletal traction (Figure 3 *B*). Roentgenograms were obtained six months after surgery when the patient had a range of motion almost identical to that of the first patient.

Case 3

A 62-year-old woman fell down the steps at her home and landed on her flexed elbow. She was placed in a posterior plaster cast at another institution and was referred here three days after injury.

Initial roentgenograms were taken (Figure 4 *A*). Examination at our clinic revealed a moderately swollen left elbow with a clean, sutured, 2-cm laceration on the posterior aspect of the left elbow. Nerve function and circulation were intact. Seven days after her injury, she underwent open reduction and internal fixation of the left distal humerus, with insertion of a Y-Vitallium plate and nine screws. The ulnar nerve was freed from the groove at surgery and was intact.

Motion was begun after 21 days. Four weeks after surgery, the patient had ulnar neuropathy; and 10 weeks after surgery, mild but definite ulnar nerve weakness was noted, with slight atrophy of the intrinsic muscles of the hand. When last seen eight months after surgery, she had a range of motion of 35 to 140° and had regained full pronation and supination. She had no sensory loss. Final films were taken eight months after surgery (Figure 4 *B* and *C*).

Case 4

A 64-year-old woman fell down some steps and landed on her right elbow, incurring a severely comminuted fracture of the supracondylar region. Sensation and circulation were intact. Three days after fracture, she underwent open reduction and internal fixation of the distal humerus with nine K-wires (Figure 5 *A*). Three and one-half weeks after her initial injury, the cast was removed and gentle active motion was begun. Six and one-half weeks after surgery, the K-wires were removed. When last seen, 14 weeks after her initial fracture, she had a range of motion of 45 to 90°, with full supination

and pronation at the elbow (Figure 5 *B*).

Comments

Dr. Bryan:

Kirschner wires tend to slip when utilized in fixing this type of fracture, unless many are used. Even nine Kirschner wires did not prevent some slippage of the fracture in Case 4. The grossly comminuted fracture cannot be held with any fixation. There is no way you can put a "bag of bones" together. However, there is no great harm done in attempting fixation by use of wires if the fragments are not dissected too extensively. Knight[7] advocated excision of the proximal portion of the olecranon to increase the range of motion in flexion and extension. Cassebaum[6] described an approach in which he simply osteotomized the olecranon and reflexed the triceps in order to get exposure. This concept is based on the observation that the olecranon fossa becomes filled with bony callus, producing a block to full motion. Therefore, if a portion of the olecranon is excised, the chances of regaining flexion-extension motion in this fracture are enhanced.

The first patient (Case 1) had an obviously dirty wound, and there was no choice except to use traction. This fracture would have been classified as a type II according to Riseborough and Radin,[1] because the fragments were not rotated. These patients do well any way you treat them. The one-screw technique is an excellent method of treating this type of fracture.

The second patient (Case 2) had a radial palsy prior to surgery. After surgery he also an ulnar palsy. Both nerves recovered completely.

The third patient (Case 3), an elderly woman, also had ulnar neuropathy despite the visualization and careful protection of the ulnar nerve.

Dr. Anthony J. Bianco, Jr.:

I wonder why many experts like Kern-Cohen[8] from Australia take the opposite view and say that these fractures need not be opened. Nonunion is very rare in this region, and this is not a weight-bearing joint. But you do want to regain motion. If you get good, painless motion, this is what you are after. What do you think?

Dr. Bryan:

This is exactly the viewpoint of Riseborough and Radin.[1] We could go back to an earlier time and quote Philip Wilson[9] reporting from the same hospital who believed in the open reduction of at least some of the fractures. He did not believe that the grossly comminuted fractures in th elderly required open reduction.

Dr. Bianco:

I agree. I think the young adult who sustai injury to this region should be operated on, bu I wonder if operative intervention does not pr mote reduced motion in the elderly.

Dr. Bryan:

There is no question that operation decreas motion in the elderly when the fracture is grossl comminuted. In the younger patient, howeve operative intervention should give a better en result. Bickel and Perry[2] got better results in th operative cases of comminuted fractures the reported.

One comment can be made regarding patie position during operation. To operate on an obes patient in the prone position is a mistake, becaus the fracture cannot be exposed adequately. Oper ation is best done with the arm over the che and the patient supine.

Dr. Bianco:

In the operative case, do you think the ulna nerve should be translocated every time?

Dr. Bryan:

I think that it should be exposed every time but translocation of the nerve can cause trouble and perhaps the nerve should be left in its groove

Dr. Charles F. Mess:

For the third patient (Case 3) who had ulna nerve neuropathy, why was not something don about the neuropathy at operation? The neurop athy had become worse within a week or two and went from a tingling to paresthesia.

Dr. Bryan:

Nothing was done about the neuropathy be cause it was not noted at operation. The woman was at home during the time that the neuropathy developed. She was improving when she returned

Dr. Charles P. Fina:

Mention was made of primary treatment o excision of fragments and arthroplasty. Are there any comments from the literature on the result of these?

Dr. Bryan:

This was done in the earlier years, and the results were good, but the treatment left a weak elbow. The key to success was never to excise bone above the condyles. If the capitellum alone was excised, an excellent result was obtained. The capitellum and the trochlea can be excised, but the condyles cannot. If they are, too much weak

ess and instability result.

Dr. James H. Dobyns:

Perhaps another point deserves elaboration. Obviously, early motion is essential and useful, but the questions are how early and on what do you base this decision.

Dr. Bryan:

If internal fixation is used, motion should be begun at three weeks. If the collar-and-cuff method is used, motion also should begin in about three weeks.

Dr. Welsch:

I believe that Miller[3] advocated motion at seven to 10 days in fractures that are securely fixed.

Dr. Bryan:

We are trying to combat what is called traumatic arthrofibrosis and similar soft-tissue adhesions around and in the joint structures. I realize every patient is a little different in this respect, but there must be some point in time where you could begin—when the pain and swelling have subsided.

I would think though that it is wiser to wait until the inflammation has subsided. In their report, on fractures of the radial head, Riseborough and Radin[1] advocated three weeks before motion is started, and their experience revealed that this gave better end results.

Dr. James S. Breivis:

I am interested in the absence of vascular injury. Is lack of such injury true for the four patients reviewed here or for all such patients reported on in the literature?

Dr. Welsch:

That includes the ones that were mentioned in the literature. There were no Volkmann contractures in the reports that I read.

Dr. Bianco:

Do you still use the Y-plate?

Dr. Bryan:

Yes. However, fixation by screws alone is better, if such fixation is possible.

Conclusions

1. Comminuted intercondylar T-fracture of the distal humerus is a serious injury that almost always produces some loss of elbow motion in flexion and extension.
2. In all but the elderly patient, open reduction and internal fixation is the method of choice.
3. Motion should be started early—no later than three weeks after injury—and continued until the recoverable range of function is maximal.
4. Occasionally, late surgical attack on the elbow joint for removal of bony overgrowth may increase motion.

The Probability of Abnormal 12-Channel Results in Normal People

When a physician orders multiple test profiles, he will observe a number of clinically well patients with one or two inexplicable abnormal results.

This is inevitable. Why? Because "normal range" is usually calculated as the Mean ± 2 Standard Deviations. Statistically this means that 95 percent of normal people will fall inside normal limits. It also means that five percent of normal people will fall outside the normal range.

One Test Vs Twelve Tests

This 95 percent approach causes little trouble if you're measuring one test. Being reasonable people, physicians expect a normal person to have a borderline abnormal test occasionally.

The trouble comes when you start measuring twelve tests at once. Then physicians complain about the large number of unexpected borderline abnormal results. Yet probability theory dictates that almost half of the normal people on whom you measure twelve tests will have at least one borderline abnormal test.[1,2]

100 Normal People

Let's take an example. Suppose you're screening 100 normal patients in your office.

You can express the probability that one of these patients has a normal value for a single test (say calcium) as 0.95. This means that 95 of the 100 patients will have a normal serum calcium.

But now take a second test, for instance, glucose. Assume the glucose result is independent of the calcium result. Again you would expect 0.95 (or 95 of the 100) patients to have normal glucose.

The Rub

Now the rub. What is the probability that one of these patients will have both a normal calcium and a normal glucose? Answer: 0.95 × 0.95 × 100, or 90 patients of the original 100. If you keep applying this law of probability to all twelve tests, you find that only 54 of 100 normal people will have all their tests within normal limits.

Here are other probabilities:

Probability of all tests normal	54%
Probability of one abnormal test	34%
Probability of two abnormal tests	10%
Probability of three or more abnormal tests	2%

What does this mean to you? It means that if you screen normal individuals with 12-channel chemistry graphs, borderline abnormal results are inevitable if the mean ± 2 Standard Deviations, or 95 percent confidence limits are used to define normal. It also means that many of these borderline abnormal results will be clinically insignificant.

Richard L. Reece, M.D.
Minneapolis, Minnesota

Encounter under the Scanning Electron Microscope

SEM reveals changes in *E. coli* exposed to antibacterial agents

The Scanning Electron Microscope (SEM) is the only instrument which gives 3-dimensional views on a microscopic level. This permits the surface morphology of microorganisms to be observed in detailed perspective. Changes in surface morphology of *E. coli* exposed to various antimicrobial agents are seen on the following page. An SEM photomicrograph of normal control *E. coli* appears above.

Different modes of antibacterial action — Similar changes in morphology

As part of a series of experiments,[1-3] strains of *E. coli* proven susceptible to each antibacterial agent were exposed to 1 MIC of the respective antibacterials for a three-hour period. Included were cell-wall-active drugs, ampicillin and cephalothin; a drug interfering with intracellular protein synthesis, tetracycline; and a chemical agent which acts by interference with para-aminobenzoic acid, sulfamethoxazole.

As seen above, elongation of the bacilli, mid-cell defects and spheroplast-like forms may be appreciated with the SEM technique. These changes in bacterial morphology were similar ... regardless of the antibacterial agent used and irrespective of its mechanism of action.

"At present, the significance of these observations in clinical infection must be considered with caution, but it is hoped that these data will stimulate a reevaluation of present concepts of the nature and role of morphological variants of bacteria exposed to a variety of antibacterial factors."[2]

It should be noted that no clinical conclusions can be drawn from this study, as it is not always possible to extrapolate *in vitro* data to humans.

L.: Scientific Exhibit presented at the 25th American Medical Association Clinical Convention, New Orleans, La., Nov. 28-Dec. 1, 1971. **2.** Klainer, A. S., and Perkins, R. L.: *Antimicrob. Agents Chemother., 1*:164, 1972. **3.** Klainer, A. S.: Data on file, Hoffmann-La Roche Inc., Nutley, N.J.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Acute, recurrent or chronic nonobstructed urinary tract infections (primarily pyelonephritis, pyelitis and cystitis) due to susceptible organisms. **Note: Carefully coordinate *in vitro* sulfonamide sensitivity tests with bacteriologic and clinical response; add aminobenzoic acid to follow-up culture media. The increasing frequency of resistant organisms limits the usefulness of antibacterials including sulfonamides, especially in chronic or recurrent urinary tract infections.** Measure sulfonamide blood levels as variations may occur; 20 mg/100 ml should be maximum total level.

Contraindications: Sulfonamide hypersensitivity; pregnancy at term and during nursing period; infants less than two months of age.

Warnings: Safety during pregnancy has not been established. Sulfonamides should not be used for group A be hemolytic streptococcal infections and will not eradicate prevent sequelae (rheumatic fever, glomerulonephritis) of su infections. Deaths from hypersensitivity reactions, agranulocy sis, aplastic anemia and other blood dyscrasias have been ported and early clinical signs (sore throat, fever, pallor, purpu or jaundice) may indicate serious blood disorders. Frequent C and urinalysis with microscopic examination are recommend during sulfonamide therapy. Insufficient data on children unc six with chronic renal disease.

Precautions: Use cautiously in patients with impaired re or hepatic function, severe allergy, bronchial asthma; in gluco 6-phosphate dehydrogenase-deficient individuals in whom do related hemolysis may occur. Maintain adequate fluid intake prevent crystalluria and stone formation.

Adverse Reactions: *Blood dyscrasias* (agranulocytos

Encounter in Clinical Practice

Control of primary bacterial offenders

Antibacterial Gantanol® (sulfamethoxazole) controls susceptible strains of *E. coli* and other gram-negative and gram-positive organisms often implicated in acute nonobstructed pyelonephritis and cystitis.

Prompt antibacterial blood and urine levels

In from 2 to 3 hours after the initial 2-Gm adult dose, antibacterial levels are present in both the blood and urine.

B.I.D./T.I.D. dosage for around-the-clock coverage

Subsequent 1-Gm doses provide up to 12 hours of antibacterial coverage. More severe u.t.i. may require a q. 8 h. dosage regimen. Either schedule provides coverage during the waking and sleeping hours—especially important during hours of sleep when normal urinary retention tends to favor bacterial proliferation.

Also effective in nonobstructed chronic and recurrent u.t.i.

It is not uncommon for the elderly and the debilitated to develop chronic and/or recurrent nonobstructed urinary tract infections such as pyelonephritis and cystitis. Such cases often respond satisfactorily to Gantanol. The increasing frequency of resistant organisms is a limitation of usefulness of antibacterial agents including sulfonamides, especially in chronic or recurrent u.t.i.

Your Option: Tablets or Suspension

Either dosage form—the Tablets or the pleasant-tasting, cherry-flavored Suspension—can provide the dependable antibacterial activity necessary to control susceptible nonobstructed cystitis and pyelonephritis. Symptomatic improvement may usually be expected in 24 to 48 hours. The usual precautions with sulfonamide therapy should be observed, including adequate fluid intake. Gantanol (sulfamethoxazole) is generally well tolerated with relative freedom from complications; the most common side effects are nausea, vomiting and diarrhea. Frequent c.b.c.'s and urinalyses with microscopic examination are recommended.

In nonobstructed cystitis and pyelonephritis due to susceptible organisms

Gantanol®
(sulfamethoxazole)
Basic Therapy

---

istic anemia, thrombocytopenia, leukopenia, hemolytic ane-
, purpura, hypoprothrombinemia and methemoglobinemia);
rgic reactions (erythema multiforme, skin eruptions, epider-
necrolysis, urticaria, serum sickness, pruritus, exfoliative
matitis, anaphylactoid reactions, periorbital edema, conjunc-
l and scleral injection, photosensitization, arthralgia and
rgic myocarditis); *gastrointestinal reactions* (nausea, emesis,
ominal pains, hepatitis, diarrhea, anorexia, pancreatitis and
natitis); *CNS reactions* (headache, peripheral neuritis, men-
depression, convulsions, ataxia, hallucinations, tinnitus, ver-
and insomnia); *miscellaneous reactions* (drug fever, chills,
c nephrosis with oliguria and anuria, periarteritis nodosa and
phenomenon). Due to certain chemical similarities with
ne goitrogens, diuretics (acetazolamide, thiazides) and oral
oglycemic agents, sulfonamides have caused rare instances
goiter production, diuresis and hypoglycemia as well as thyroid malignancies in rats following long-term administration. Cross-sensitivity with these agents may exist.

Dosage: Systemic sulfonamides are contraindicated in infants under 2 months of age (except adjunctively with pyrimethamine in congenital toxoplasmosis).

Usual adult dosage: 2 Gm (4 tabs or teasp.) initially, then 1 Gm *b.i.d.* or *t.i.d.* depending on severity of infection.

Usual child's dosage: 0.5 Gm (1 tab or teasp.)/20 lbs of body weight initially, then 0.25 Gm/20 lbs *b.i.d.* Maximum dose should not exceed 75 mg/kg/24 hrs.

Supplied: Tablets, 0.5 Gm sulfamethoxazole; Suspension, 0.5 Gm sulfamethoxazole/teaspoonful.

In Memoriam

'Tis true; 'tis certain; man though dead retains part of himself; the immortal mind remains—Homer

CARL J. MARTINSON, M.D.

Dr. Carl J. Martinson, 84, Wayzata surgeon, died July 25. Born in Stillwater, Minnesota, Dr. Martinson obtained his medical education at the College of Medical Evangelists in Loma Linda, California. He interned at the Los Angeles General Hospital and practiced in California until in 1927 when he moved to Wayzata.

Dr. Martinson is a member of the Hennepin County Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Alma, and two sons, Doctors Arthur J. of California and Elmer J. of Wayzata.

CECIL A. WILMOT, M.D.

Dr. Cecil A. Wilmot, 61, Litchfield physician, died July 19. He was born in St. Charles, Minnesota, and obtained his medical education at the University of Minnesota.

Dr. Wilmot was a member of the Mid Minnesota Medical Society, the American Medical Assocation and the Minnesota State Medical Association.

He is survived by his wife, Isabel, and a son, Dr. Thomas of Winona.

SHU KANG HO, M.D.

Dr. Shu Kang Ho, 50, staff anesthesiologist at Bethesda Hospital, died July 17. He was born in Chekiang, China, and obtained his medical education at the National Medical College in China. He did postgraduate work at the University of Minnesota for three years.

Dr. Ho was a member of the Ramsey Medical Society, the American Society for Anesthesiologists, a Diplomate of the American Board of Anesthesiologists, a member of the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Beverly, four sons and two daughters.

FRANK R. GRATZEK, M.D.

Dr. Frank R. Gratzek, 73, retired Minneapolis radiologist, died July 18. He had been affiliated with the former St. Andrew's Hospital and St. Mary's and the University of Minnesota Hospitals. Dr. Gratzek also served as an instructor in radiology at the University of Minnesota Hospitals.

A graduate of the University of Minnesota Medical School, Dr. Gratzek was a member of the Hennepin County Medical Society and the American Medical Association and an associate member of the Minnesota State Medical Association.

Dr. Gratzek is survived by his wife, Mary.

JAMES H. BENDER, M.D.

Dr. James H. Bender, 64, Brainerd physician, died July 4. He was born in Two Harbors and had resided in Brainerd for the past 26 years.

He was founder and a member of the Lake Region Clinic, a member of St. Joseph's hospital medical staff, the Upper Mississippi Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Alice, two sons, Ronald and Robert, and two daughters, Kathryn and Mary.

HENDRIK J. SVIEN, M.D.

Dr. Hendrik J. Svien, Rochester neurosurgeon associate professor of neurologic surgery in the Mayo Foundation Graduate School, died June 29. He was born at Dennison, Minnesota, and obtained his medical education at the University of Minnesota Medical School.

Dr. Svien was a member of the Mayo Clinic, the Society of Neurological Surgeons, the Zumbro Valley Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, Nancy, and two children.

LILLIAN L. NYE, M.D.

Dr. Lillian Nye, 87, St. Paul chemist, physician and humanitarian, died July 28. She was in Yale University Medical School's first class that graduated women and later shifted to the University of Minnesota where in later years she was honored as one of its distinguished "emertius" graduates. She had her B.S. and M.A. degrees in chemistry and taught the subject at the University of Minnesota before entering medical school. In addition, she was the first women physician in the St. Paul public schools, and it was her influence that developed family nursing service clinics first at Ancker Hospital.

Her diplomas and testimonials were many—life membership in the American College of Physicians and the American Academy of Pediatrics, Distinguished Alumnus of the University of Minnesota, recipient of the Girl Scouts' Golden Eaglet award, recipient of the University of Minnesota Outstanding Achievement Award and membership in many Canadian and foreign honorary medical societies. In addition she was a member of the Ramsey County Medical Society and the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

She is survived by many nieces and nephews.

When a child is abandoned, somebody at least leaves it on a doorstep.

Once a man starts downhill, it doesn't take him long to reach bottom.

Four years ago, he wasn't much different from you.

Then somehow he lost his job. His wife left. His kids went off someplace. Life just fell apart.

Homeless, forgotten men like this are among the people in our town who need your help.

Poor people, sick people, disturbed people, old people are counting on you to help change their lives.

Give the United Way. Please.

a advertising contributed for the public good

If you don't do it, it won't get done.

"For generations my family has insisted on Donnagel®-PG," says active young matron Mrs. T. Farnsworth Lipp (of the Upper Lipps), shown here with her charming son. "All the benefits of paregoric—without the unpleasant taste, don't you know? And Junior thinks Donnagel-PG tastes so much like bananas that I never worry about a slip between spoon and Lipp."

A Matter of Taste

ith or without a silver spoon, a most tasteful solution in treating acute, non-specific r as: all the benefits of paregoric, without the unpleasant taste. Donnagel®-PG treats or anying cramping, tenesmus, and nausea as well as the diarrhea itself. coughs are back...

lear the tract!

The coughing season is here again. Time to rely on the four Robitussins and Cough Calmers to help clear the lower respiratory tract. All contain glyceryl guaiacolate, the efficient expectorant that works systemically to help increase the output of lower respiratory tract fluid. The enhanced flow of less viscid secretions soothes the tracheobronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise. Available on your prescription or recommendation.

For coughs of colds and "flu"

Robitussin®

Each 5 cc. contains:

Glyceryl guaiacolate ..... 100.0 mg.
Alcohol, 3.5%

For unproductive allergic coughs

Robitussin A-C® C

Each 5 cc. contains:

Glyceryl guaiacolate ..... 100.0 mg.
Pheniramine maleate ..... 7.5 mg.
Codeine phosphate ..... 10.0 mg.
(warning: may be habit forming)
Alcohol, 3.5%

Non-narcotic for 6-8 hr. cough control

Robitussin-DM®

Each 5 cc. contains:

Glyceryl guaiacolate ..... 100.0 mg.
Dextromethorphan hydrobromide ..... 15.0 mg.
Alcohol, 1.4%

Clears sinuses and nasal stuffiness as it relieves cough

Robitussin-PE®

Each 5 cc. contains:

Glyceryl guaiacolate ..... 100.0 mg.
Phenylephrine hydrochloride ..... 10.0 mg.
Alcohol, 1.4%

Robitussin-DM in solid form for "coughs on the go"

Cough Calmers®

Each Cough Calmer contains:

Glyceryl guaiacolate ..... 50.0 mg.
Dextromethorphan hydrobromide ..... 7.5 mg.

A·H·ROBINS

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

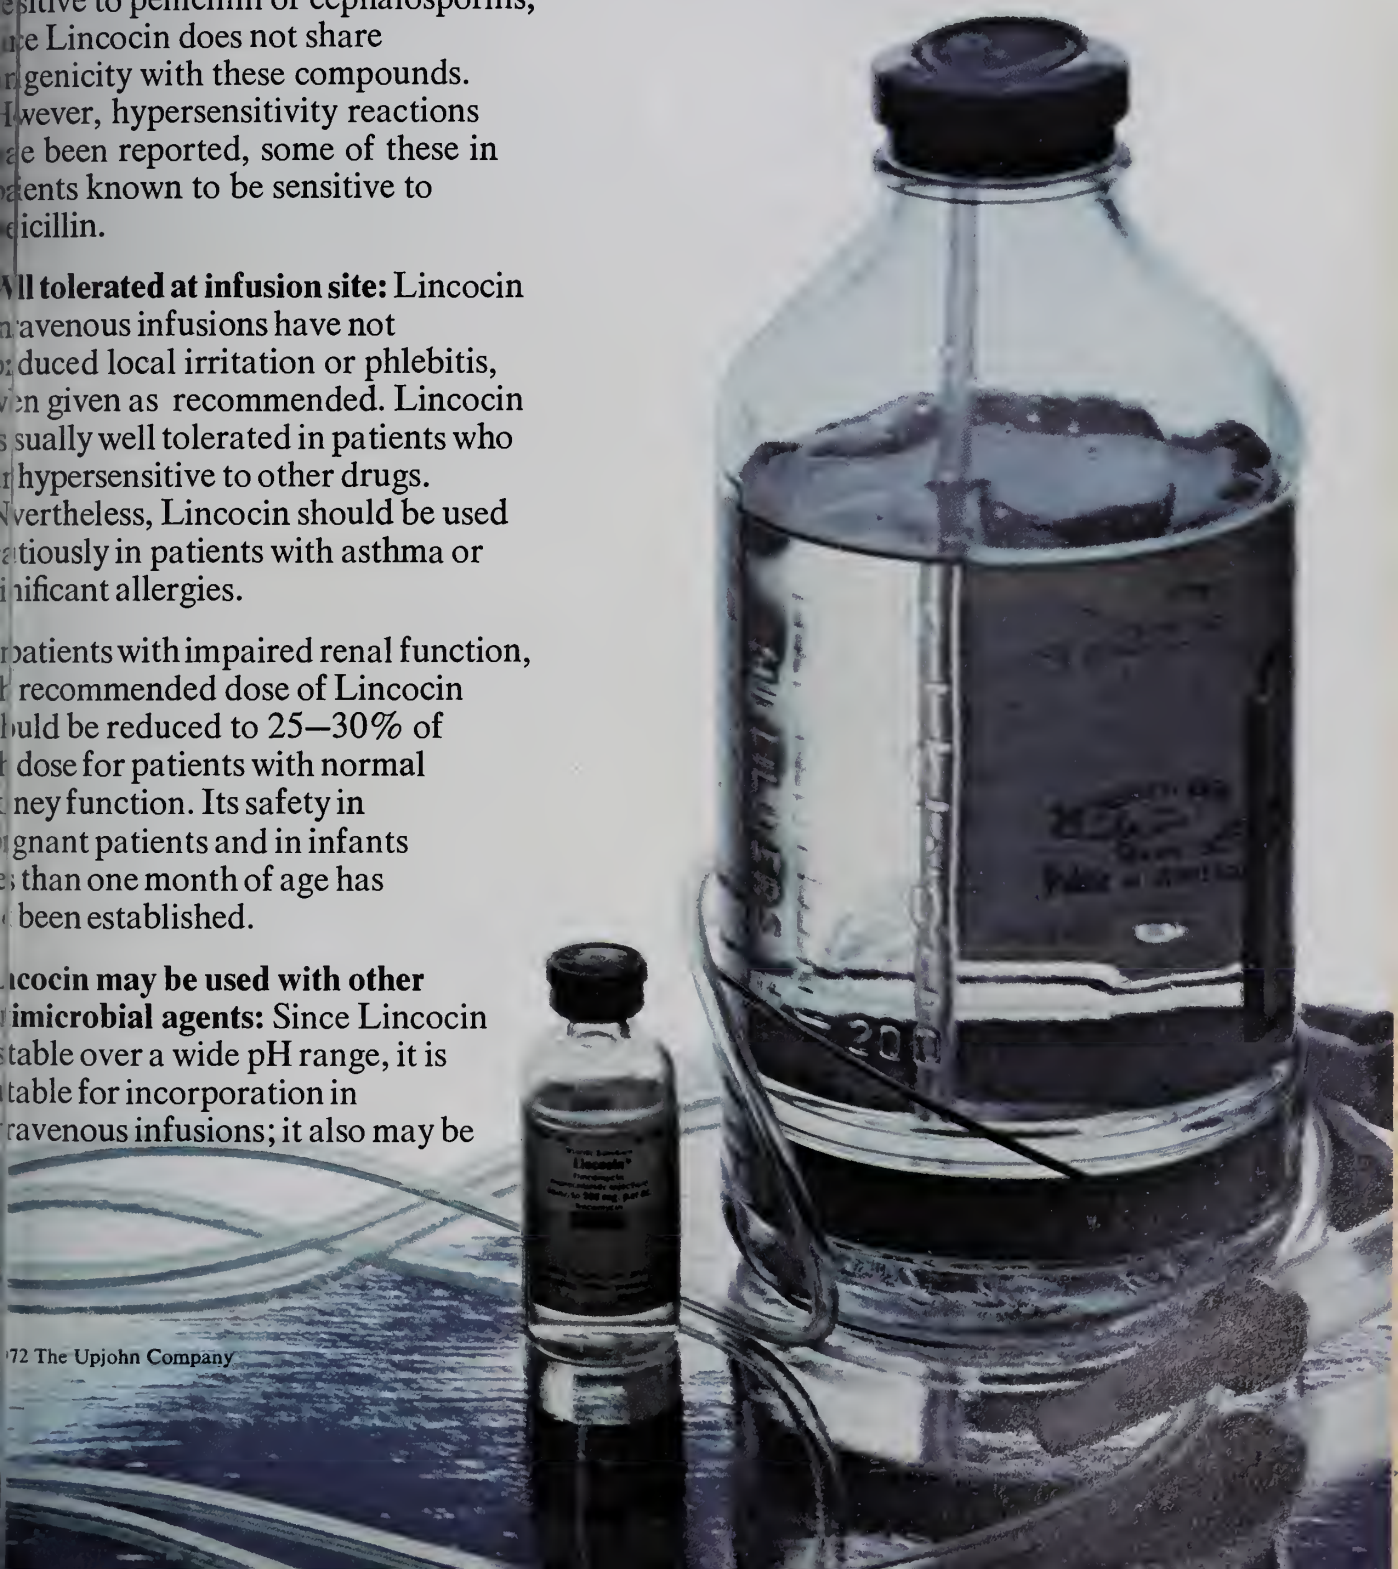
In usual IV doses, Lincocin (lincomyci hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water But when 4 grams or more per day is given, Lincocin should be diluted in n less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

nfections caused by susceptible strains
f neumococci, streptococci, and
taphylococci, including penicillin-
estant strains. Staphylococcal strains
estant to Lincocin (lincomycin
yrochloride, Upjohn) have been
covered. Before initiating therapy,
ulture and susceptibility studies should
performed. Lincocin has proved
aluable in treating patients hyper-
sitive to penicillin or cephalosporins,
ce Lincocin does not share
genicity with these compounds.
However, hypersensitivity reactions
ve been reported, some of these in
gents known to be sensitive to
enicillin.

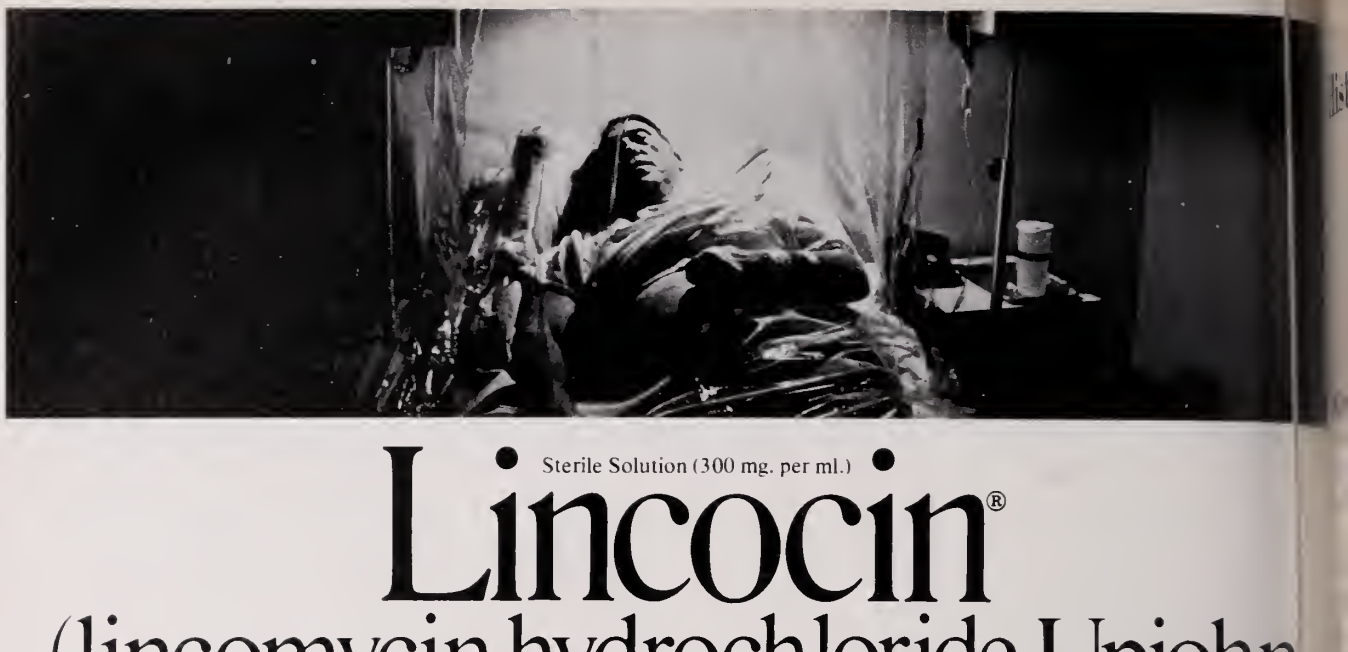
Well tolerated at infusion site: Lincocin
intravenous infusions have not
produced local irritation or phlebitis,
when given as recommended. Lincocin
is usually well tolerated in patients who
are hypersensitive to other drugs.
Nevertheless, Lincocin should be used
cautiously in patients with asthma or
significant allergies.

In patients with impaired renal function,
the recommended dose of Lincocin
should be reduced to 25–30% of
the dose for patients with normal
kidney function. Its safety in
pregnant patients and in infants
less than one month of age has
not been established.



**Lincocin may be used with other
antimicrobial agents:** Since Lincocin
is stable over a wide pH range, it is
compatible for incorporation in
intravenous infusions; it also may be
administered concomitantly with other
antimicrobial agents when indicated.
However, Lincocin should not be used
with erythromycin, as *in vitro* antagonism
has been reported.

Lincocin®



Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

'72 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatment. *Skin and mucous membranes*—Skin rashes, urticaria, vaginitis, and rare instances of exfoliative and vesiculobullous dermatitis have been reported. *Liver*—Although no direct relationship to liver dysfunction is established, jaundice and abnormal liver function tests (particularly serum transaminase) have been observed in a few instances. *Cardiovascular*—Instances of hypotension following parenteral administration have been reported particularly after too rapid IV administration. Rare instances of cardiopulmonary arrest have been reported after too rapid IV administration. If 4.0 grams or more are administered IV, dilute in 500 ml of fluid and administer no faster than 100 ml per hour. *Special senses*—Tinnitus and vertigo have been reported occasionally. *Local reactions*—Excellent local tolerance demonstrated to intramuscularly administered Lincocin (lincomycin hydrochloride). Reports of pain following injection have been infrequent. Intravenous administration of Lincocin in 250 to 500 ml of 5% glucose in distilled water or normal saline has produced no local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500 mg* Capsules—bottles of 24 and 100. *Sterile Solution, 300 mg per ml*—2 and 10 ml vials and 2 ml syringe. *Syrup, 250 mg per 5 ml*—60 ml and pint bottles.

Upjohn

Dr. Henry Stanley Plummer
(1874-1936) (Historical Vignette)

THOMAS E. KEYS, M.A., Sc.D. (honorary)

WHEN I CAME to Rochester in 1934, Dr. Henry Plummer (Figure 1) was in his sixtieth year. He often would come up to the library and thus I came to know him fairly well.

At that time I knew little about the many outstanding things he had accomplished for the Mayo Clinic and about his international reputation. But occasionally he took me into his confidence, and would reminisce about his experiences. This physician who pioneered in the study and treatment of thyroid diseases was indeed a genius. He combined great engineering ability with other wonderful attributes, including profound philosophical knowledge. He was able to combine his amazing talents for the good of the institution. Perhaps the people who appreciated him the most were the Drs. Will and Charlie Mayo.

Appearance and Mannerisms

As mentioned by Clapesattle,[1] "Dr. Will Mayo himself said the hiring of Henry Plummer was the best day's work he ever did for the Clinic." Dr. Samuel F. Haines,[2] of the clinic's staff, himself a prominent expert in endocrinology who profited by many years of close association with Dr. Plummer, described him as follows:

"Plummer was tall, spare, and stooped. He had learned to avoid distraction so well that he seemed unapproachable. Thus it was surprising, when he had apparently completely disregarded a question, to have him answer it hours or days later. His ability to become fully absorbed in one subject was so great that he appeared to be unmindful of his associates at times when they wanted him to consider other problems, but it was well recognized by those who worked with him that this same characteristic was responsible for some of his great productiveness. He was a kind and considerate man, willing to devote unlimited time to his patients and to his students."

Because of his powerful concentration he often appeared to be absentminded. Many stories are told about him in this respect. For instance, it is said that he sold his automobile, a Cadillac, to a clinic fellow. But seeing it in the parking lot later, Dr. Plummer drove it home as usual! This obliviousness even extended to his family circle. Mrs. Plummer recalled with a smile meeting her husband face to face one day in a clinic corridor as he strode along to an appointment. His preoccupied expression changed only slightly as he nodded with a formal bow and smile as if to say, "You're someone I must know!" Another story is a typical one. Dr. Plummer invited several of his friends to a luncheon at a hotel in Denver, Colorado, during a meeting of the American Goiter Association. When the check came, he forgot about paying the bill, so one of his friends picked up the tab—but when the waitress brought the change, Dr. Plummer pocketed it.

Fig. 1—Dr. H. S. Plummer in 1936.

Mr. Keys is Senior Library Consultant, Mayo Clinic Library, Rochester, Minnesota.

Unpublished chapter from the College of the Medical Book. The Memoirs of Thomas E. Keys.

See editorial, page 912.

Work on the Esophagus

Dr. Plummer's early work on the esophagus highlights his genius well. As mentioned by Fredrick A. Willius,[3] he made the differential diagnosis between cardiospasm (contraction of the cardiac sphincter) and stricture due to ulceration. His pioneer work on the diagnosis of and treatment for hysterical dysphagia,[4] esophageal stricture,[5] and achalasia[5] was remarkable. The many patients—especially children—who in those days suffered from esophageal stricture due to ingestion of lye or acids were of great concern to him. Frequently ulceration led to complete closure of the esophagus, and the only procedure then available to sustain life was gastrostomy. The usual attempt to dilate the esophageal stricture by forcibly passing bougies from the stomach up through the esophagus often failed. On occasion efforts might be made to cut the stricture. The patient was asked to swallow the end of a silk thread[6] which, if it entered the stomach, could be reached via the gastrostomy opening. A piece of fishline then was attached to the silk thread and drawn up through the esophagus and out through the mouth. By pulling the fishline back and forth from both ends, efforts were made to cut the stricture, but sometimes without benefit.

According to Willius,[3] Dr. Plummer realized the importance of avoiding this type of surgery whenever possible. In 1906 he called attention to the use of silk thread as a guide in procedures for relief of strictures. The patient swallowed six yards of thread, one end of which was retained at the mouth. After as much thread as possible had passed into the intestine, a perforated sound was slipped over the retained end and passed through the mouth and into the esophagus; and with the thread drawn tight, the sound readily entered the stomach. Dr. Plummer designed and made the sounds himself. This form of therapy was safer and easier than gastrostomy and for many patients it was quite sufficient.

Dr. Plummer[5] was also an advocate of the hydrostatic dilator for the treatment of esophageal obstruction and a skillful remover of foreign objects from that organ. He had at home an extensive machine shop for making fine tools and instruments. On some occasions he hurried home from the clinic to make an instrument for a specific patient in critical condition. The instrument would be plated afterward, when the immediate crisis was past.

The First Clinic Building, 1912-1914

As the need arose, the Mayo Clinic added laboratories and equipment.[7] Also when an X-ray machine was procured, Dr. Plummer was placed in charge of this new apparatus. Gradually the laboratories were organized under his supervision.

After a time it became apparent, at least to Dr. Plummer, that a specially designed building was needed to embrace the several units and to coordinate the clinic's practice of medicine. With some persuasion, he got Dr. Will to accept this idea. The first clinic building, which had been formulated in Dr. Plummer's mind for several years, was begun in 1912 and finished in 1914. The prime objective for the new building was to create an efficient system of examination for patients along with necessary laboratories and sufficient storage for case records later to be used in research. In addition, Dr. Plummer felt the importance of creating a harmonious and artistic building. To this end, he went to the famous Rookwood Pottery firm in Cincinnati, Ohio. He described to them his wish for tile to cover the walls of the main lobby and form an entire double stairway. The firm was flabbergasted by such an idea, but before leaving he had convinced them of its feasibility. Though the matching fountain has been removed, that elegant stairway still stands in what is called the 1914 Mayo Clinic Building.

At completion of the clinic building a gala party was held in the main lobby. Dr. Plummer always had an unusually close relationship with the workmen at all levels; and almost to a man the architects, artisans, and laborers who started the project with him were on hand to share in the proud accomplishment of the completed building.

Mechanical Innovations

Dr. Plummer put his mechanical ideas to work. He devised the system of colored lights to indicate the need for special consultants in the diagnostic rooms. He figured out one of the first complete intercommunication telephone systems in the United States. He designed the tube system for sending patients' histories underground from the clinic building to St. Mary's Hospital. These are but a few of his achievements.

The record system itself had been established by Dr. Plummer. Previously each physician had

maintained his own ledger of clinical data, and cross reference for purposes of practice or research was extremely inconvenient. The Mayos wanted these purposes served, and Dr. Plummer based his solution on the radical concept that the clinical data belonged not solely to whichever doctor had recorded them but to the group and should be immediately available to any member. This could be accomplished by a system in which each patient's record was a unit and all units were comprised in a single index, and Dr. Plummer set out to devise one. After much thinking for himself, as mentioned by Dr. L. T. Kurland (unpublished manuscript, 1968), he visited other medical institutions but found no help; so he turned to business and industry for assistance. The system he subsequently evolved and introduced in 1907 became a model for medical records; and even with today's computerization, it is essentially this system that is still maintained. About 1935, when some 60,000 patients were being seen each year, it was necessary to develop a detailed diagnostic and subject cross-index. Miss Mabel Root, a friend of Mrs. Plummer, became the medical record librarian and refined the indexing. When Dr. Joseph Berkson became head of the Section on Medical Statistics in 1933, he saw the value of the Plummer-Root system. Dr. Berkson introduced an automated case-retrieval process, but that is another story.

Interest in the Thyroid Gland

As suggested by Willius[3] in his excellent account, Dr. Plummer's interest in patients with goiter[8] had been aroused in childhood when he accompanied his physician father on calls. One patient seen had an exceedingly large goiter for which Dr. Will Mayo successfully operated.

Following in his father's footsteps, young Henry received his medical degree from Northwestern University in 1898; and he practiced with his father at Racine, Minnesota, not far from Rochester. He joined the Mayo Clinic in 1901 as a member of the permanent staff. About this time Dr. Charles Mayo became interested in the thyroid gland, and from that time for many years operated on the thyroid. Dr. Plummer and Dr. Charlie worked together and wrote a small monograph on the subject which is a classic.[9] Dr. Charlie and Dr. Plummer were responsible for hiring Dr. Edward C. Kendall to head the Section of Biochemistry in 1914 and Dr. Kendall became the discoverer of thyroxin.

But to return to our story. Dr. Plummer made outstanding discoveries in the treatment of thyroid disorders. "His studies on the effect of iodine in the preoperative treatment of exophthalmic goiter . . . led to an immediate reduction of the operative mortality in this disease . . ."[10]

The 1928 Building

Dr. Plummer's medical and scientific achievements have been chronicled by Haines, W. J. Mayo, Willius, and others. The achievement which is his monument is the 1928 Mayo Clinic Building, now called the Plummer Building (Figure 2).

Hardly had the 1914 building been completed when it became evident that more extensive space for facilities would be needed. From that time until the completion of the Plummer Building in 1928, much of Dr. Plummer's time and energy were directed toward this project. A building committee was appointed; but it seldom met, as for practical purposes Dr. Plummer was the committee. He met often with the architects, especially Tom Ellerbe and later Edgar W. Buenger. Much time and effort went into the design of the 1928 building. It is said that when the time had come to excavate, Dr. Will became uncertain as

Fig. 2—The Plummer Building of the Mayo Clinic, completed in 1928.

to the wisdom of undertaking this large project. He consulted with Dr. Plummer about this; but when Dr. Will left the room, Dr. Plummer telephoned the contractor, Mr. Garfield Schwartz: "Get up early and have your men dig a big hole and start the new building."

When Dr. Will saw the excavation he said, "Henry, I guess we might as well go ahead; there is no stopping you, anyway!" And it is said that Dr. Mayo never regretted the decision to go ahead.

This building, which is a work of art, contains features that cannot be replicated. Frank Lloyd Wright said that the clinic library's reading room, first occupied in 1929, was "attractive and commodious"—strong words from Mr. Wright, who was not often complimentary about the work of other architects.

Dr. Plummer anticipated that the library would expand upward and downward. He had an elevator shaft made from the 11th to the 16th floors. When the library was remodeled in 1955, all that was necessary was to add the cab and other equipment. Plummer Hall (on the 14th floor) was converted from a lecture hall to library use in 1968 with little effort, thanks to Dr. Plummer's thinking in 1927 or earlier.

The Browsing Room

Dr. Plummer conceived of the idea of a Browsing Room Library at the clinic for the use of the physicians. He personally selected some 800 nonmedical books, including classics of English and American literature, travel, gardening, exploration, antiquities, and other books covering man's scope of knowledge. He thought that medical men should know of other fields besides medicine. Even if they looked only at the backs of the books, they might learn something. If they devoted a half an hour a day to this nonmedical reading, they would improve their cultural understanding. He realized that men of medicine had little time in medical school and in later training years for this type of reading.

Dr. Plummer also gave me another reason for the Browsing Room. When a fellow or staff member is doing a research project, he tends to get stymied—that is, he runs out of ideas. Dr. Plummer thought that if such a person would come to the Browsing Room and read or browse, he might "click" on how to proceed with his research project.

Artistic Features

Dr. Henry Plummer's fine hand was in everything connected with the Plummer Building. This included the ceilings of the several large waiting rooms. He found an Italian firm, Brioschi and Sons, in St. Paul who were experts in the art of painting artistic ceilings. Mr. Brioschi also designed some of the modeling when he was a patient in the Kahler Hospital with exophthalmic goiter. All of that work is attractive. The elegant ceiling of the 12th-floor Reading Room was executed by Jean K. Kaufmann, now of Fennville, Michigan. Mr. Kaufmann, who received his training in Germany, was also responsible for the ceiling in the old Board of Governor's room. Around the frieze and on the beams of the Reading Room's ceiling are the names of illustrious men and women in medicine and the allied sciences, chosen by Dr. Plummer from his wide reading.

This splendid building is a work of art in Moorish-Gothic style. The finest craftsmen were employed to mould and cast the ornamental bronzes, to sculpture decorations of imported marbles for the interior and exterior, and to paint designs throughout. The building is truly a monument to Dr. Plummer's artistic knowledge and ability, and his responsibility for it is commemorated by a carving set into its outer wall at the first-floor level (Figure 3).

Hobbies

In spite of working prodigiously on both his medical practice and the designing of the clinic building, Dr. Plummer found time for a whole

Fig. 3—Stone inset at southwest corner of the Plummer Building, commemorating Dr. Plummer's design of it.

gmut of hobbies. In his early days at the clinic, fore he married Daisy Berkman, who was a ece of Drs. Will and Charlie, he led numerous mping trips to lakes near Rochester, organizing e whole outing, providing tents for the young en, and setting up all sorts of recreational facili-s, including temporary tennis courts. Some-iat of a gourmand himself, he even planned the od.

Later, for family use, Dr. Plummer had custom-ilt camping equipment. He must have been one Abercrombie and Fitch's best customers, for visits to New York he collected every available mfort for their trips. The wilderness had no lequate accommodations in those days, but with eir deluxe camping equipment, the Plummers joyed touring the national parks and beauty ots of the northern and western parts of the untry and stopping to hunt and fish in some of e choice areas.

Always lovers of nature, the Plummers in the rly days of their marriage owned a country me on Lake Shady at Oronoco with Dr. and Irs. E. Starr Judd. Mrs. Judd also was a niece f the senior Mayos.

The Plummer Cruiser

Soon after giving the Oronoco cottage to the WCA, Dr. Plummer purchased a small cruiser hich was kept at Wabasha on the Mississippi iver. From then on, often with guests, the lummers spent summer weekends on the river. n a trip to New York in the spring of 1936, he ought a larger boat. That summer Dr. and Mrs. lummer initiated the new craft by personally uiding it through inland waters from New York ity to Wabasha, Minnesota. A log kept by Mrs. lummer tells the interesting story of their pass-ng the Statue of Liberty, going up the Hudson nd through the Great Lakes, their experiences on he Marine railways of Canada, with rough waters hrough beautiful Georgian Bay, the stench of the hicago River, the trip through the Illinois River nd canals to the Mississippi, and home base at Wabasha.

The Plummer Home

Earlier, Dr. Plummer had spent countless hours lesigning the English Tudor mansion built on a ill which was then outside the city limits, south of Rochester (Figure 4). Plans for the extensive lawns and flower gardens surrounding the house received much of his attention. In the years when the house was in construction, he studied exhaustively all the books he could gather on the English garden. The resultant landscaping conformed perfectly with the English home, and both Dr. and Mrs. Plummer devoted much time and attention throughout their busy lives to keeping the grounds beautiful.

Fig. 4—Home designed by Dr. Plummer for himself and Mrs. Plummer, which was completed in 1924.

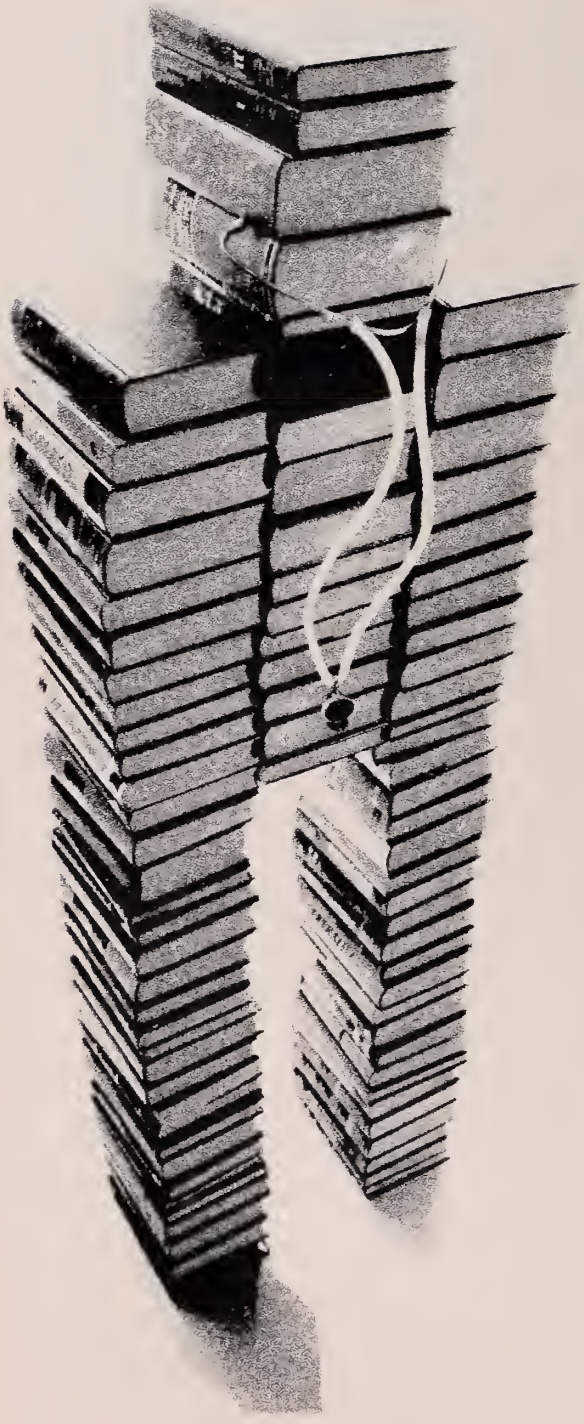
Dr. Plummer Designs a Desk

In 1935 I became reference librarian. On one of his visits to the library, I asked Dr. Plummer if it would be possible for me to have a desk in the Reading Room. He liked the idea and designed a kneehole desk for me, taking into account my proportions. Made by Linden's Glass Company in Chicago from a fine grade of whole matched walnut, in keeping with the other furniture, it is a beautiful piece and is still in the same room.

After Dr. Plummer's death I frequently visited Mrs. Plummer in their beautiful home. Many of Dr. Plummer's books were still in his library. On one occasion I asked Mrs. Plummer whether Dr. Plummer's Baskerville Bible, the elephant folio (1763), was still in his personal library. She said it was, and asked if I would like to have it for the Browsing Room.

I answered, "Yes, we would be delighted to have it."

Mrs. Plummer said, "I'll send my man out with it tomorrow!"



I said, "I'll be your man and take it to the Browsing Room today!"

Acknowledgment

Appreciation is given to Drs. Herman Moersch and Waltman Walters for some of the medical information related in this paper.

ST. CLOUD, MINNESOTA—Psychiatrists needed for Psychiatric Service, VA Hospital. Unit System with a variety of therapeutic approaches. Growing Outpatient Service. Fully staffed and newly equipped TV studio and hospital-wide CCTV network available for creative ideas to therapy, education and research. Training affiliations in social work, psychology, nursing, occupational therapy. Three local colleges with many cultural and educational advantages. License in any state accepted. Financial assistance in moving. Liberal vacation, sick and health benefits. Excellent retirement plan. Salary dependent on professional qualifications. Nondiscrimination in employment. Write or phone collect: Chief of Staff, 612-252-1670.

2 ANESTHESIOLOGISTS, (Board Eligible/Certified) wanted to join 2 in 48 man multi-specialty group. Clinic located in Petoskey on Little Traverse Bay in heart of Boyne Country. 7,000 community. Many fringe benefits. Start $32,000. Contact: B. A. Zelt, M.D., Burns Clinic Medical Center, P. C. Petroskey, Michigan 49770.

NORTHFIELD, MINN. GENERAL PRACTITIONER wanted to join busy two-man clinic. No investment. Early partnership. Lab and Xray in office. Excellent hospital. Northfield Physicians and Surgeons, P.A., Bernard Street, M.D. and David C. Halvorson, M.D., Northfield, Minn. 55057.

WANTED—INTERNIST AND GENERAL SURGEON; Board Qualified; for four man group in Iowa; two Internists and two Surgeons; own building; large modern hospital; Midwest shopping and medical center; 30,000; well balanced economy; 2 hours to three large cities; lake resort 10 miles away; hunting and fishing area; excellent school system; Junior college; art gallery; superb library facilities. Salary $25,000 plus bonus, depending on qualification. Early partnership. Write: G. I. Tice, M.D., 121 Third Street N.W., Mason City, Iowa 50401.

MEDICAL SUITE in newer building, approximately 800 sq. ft. Available Nov. 1, 1972. 4200 Cedar Ave., Minneapolis. Ideal location for General Practitioner, joint reception room with dentist's office. Will show after office hours and weekends. Presently occupied by physician. Call 724-9848 or 724-4244. Write Danish American Center, 4200 Cedar Avenue South, Minneapolis.

Book Reports

BONE TUMORS by Louis Lichtenstein, M.D., C. V. Mosby Co., 441 pp, $24.50

Long one of the bookshelf standards in the field of bone tumors, this book has been gradually enlarged and revised, but still resembles the original 1952 edition. The number of illustrations has increased from 155 to 496. There has been scattered updating where indicated and the typography has improved. The book remains small, readily understood, and is enriched with the author's extensive personal experience. The discussion of each type of bone tumor comprises a chapter that starts with historical background and continues with clinical features, roentgenographic findings, pathologic features and treatment. One regrets only that there is not a more detailed discussion of the non-tumorous conditions, such as fibrous dysplasia and the various cysts of bone. The book remains a necessary handbook for all physicians concerned with the diagnosis and treatment of bone tumors.

Robert Woodburn, M.D.
St. Paul, Minnesota

THE CARE OF MINOR HAND INJURIES. 3rd Ed. C. V. Mosby Co. 1972 by Adrian E. Flatt.

Dr. Flatt has superbly created a book for reference for the physician confronted with an injured hand.

The opening chapters dealing with functional anatomy and principles of care are concise, well-illustrated, and free of many extraneous facts and trivia often expounded by hand surgeons which have little, if any, significance to those not completely trained in this exacting field. The remainder of the text deals with specific injuries related to the soft tissues and bones of the hand, and most have been revised to include newer methods of treatment.

The book is well-indexed and the bibliography completed to give the reader easy access to further references regarding a particular topic. This book is highly recommended for anyone treating injuries of the hand and particularly should be available for those who do so only on occasion.

Lee C. Detenbeck, M.D.
Rochester, Minnesota

A PRIMER OF ELECTROCARDIOGRAPHY by George E. Burch and Travis Winsor; 6th Edition, 1972, Lea and Febiger; 292 pages.

These authors published their first edition of this book in 1945. The definition of the word primer, "an elementary textbook," has been nicely adhered to in their presentation of basic principles of this important modality.

The first three chapters cover the theoretical electronic and physiologic phenomena of electrocardiography plus wave form and lead placements. The fourth chapter provides the reader with a concise view of arrhythmias, making certain that the basic physiologic considerations of impulse propagation are well founded in preparation for future rhythm disturbance interpretation. The fifth chapter entitled "Clinical Applications" is short and sketchy in its practical subject materials. It touches briefly on vectorcardiography, though not enough to be of real value to the beginning student.

The book is a virtual carbon copy of the 1966 edition with the addition of his Bundle electrography. It would have benefited from a discussion of some of the new clinical entities and their recently recognized electrocardiographic manifestations—e.g. hypertrophic subaortic stenosis and true high posterior infarction—plus some more specific guidelines on the criteria for diagnosis of cardiac chamber hypertrophy.

NOVEMBER, 1972

The negative power of clinically significant anxiety in angina pectoris...

This man feels he is living on borrowed time.

During anginal attacks, patients may suffer intense apprehension. More frequently, however, they experience a continuing sense of less severe but nonetheless disproportionate anxiety.

Reduction of such clinically significant anxiety is important, since undue emotional stress may precipitate further anginal episodes.

Adjunctive Librium (chlordiazepoxide HCl) may be especially suitable for relief of clinically significant anxiety and emotional tension in anginal patients because of its generally prompt therapeutic effectiveness and wide margin of safety. In a recent double-blind randomized study,* Librium (chlordiazepoxide HCl) was administered for relief of moderate anxiety in 20 anginal patients seen in office practice over a 20-week period. Symptoms of emotional distress related to anxiety were rated at base-line, one week, two weeks and monthly thereafter. Relief was obtained notably early in therapy. The clinical results demonstrated that Librium offers the coronary patient an antianxiety drug that, in the author's opinion, is both effective and safe. In general use, the most common side effects reported have been drowsiness, ataxia and confusion, particularly in the elderly and debilitated. (See summary of prescribing information.)

Librium (chlordiazepoxide HCl) is used concomitantly with certain specific medications of other classes of drugs, such as cardiac glycosides, diuretics and antihypertensive agents, whenever anxiety is clinically significant. The drug should be discontinued after anxiety has been reduced to appropriate levels.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

BRING 'EM BACK ALIVE!

Should children be deprived of milk because of "lactose intolerance?"

No, according to the Protein Advisory Group of the United Nations.

In a special report, the PAG stated, "It would be highly inappropriate, on the basis of present evidence, to discourage programs to improve milk supplies and increase milk consumption among children because of fear of milk intolerance." The statement emphasizes that low lactase activity and results obtained in tests with high lactose loads are not adequate indications of milk intolerance.

The statement also affirms the advisability of using milk as an excellent source of protein in child feeding programs.

Dairy Council is sponsoring further research on lactose intolerance. This is just another of the many areas of interest of Dairy Council, in the pursuit of better health for everyone through sound nutrition practices.

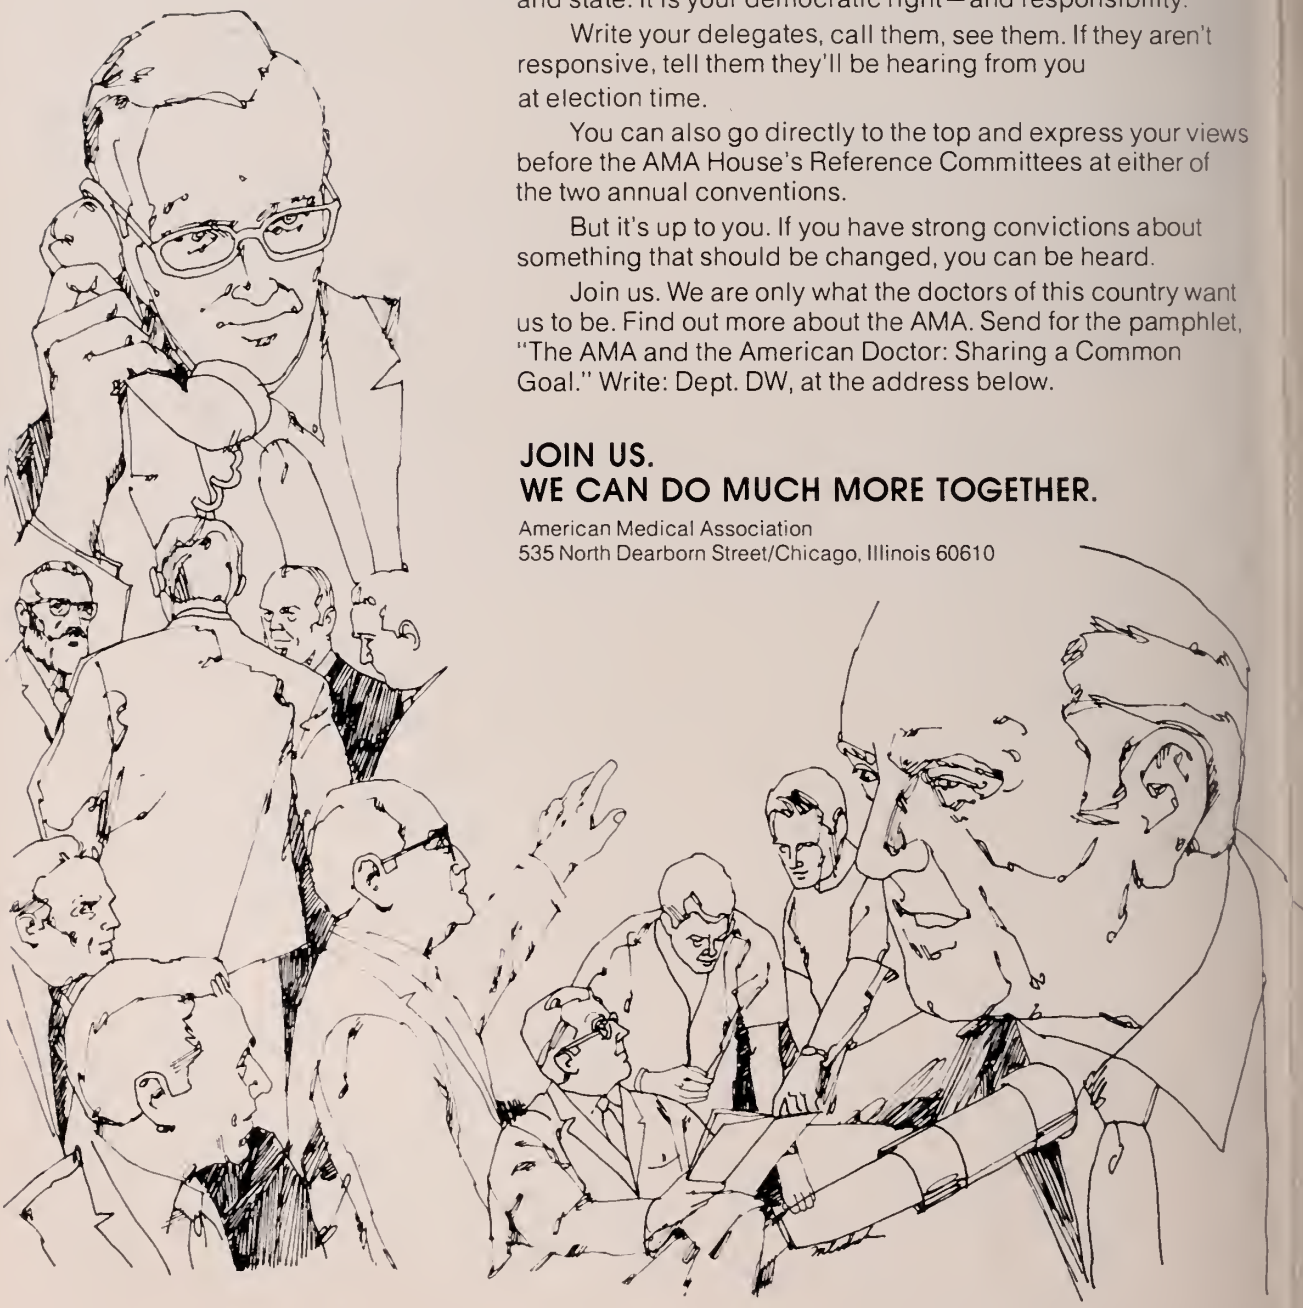
Change the AMA!

Maybe you're one of those doctors at odds with some AMA policies. Your question is: how do you change them?

First, consider who sets those policies. In a real sense, it is you. You elect the delegates to your state association. They in turn elect the delegates who will represent your views in the AMA House.

As an active, involved member, you can influence policy by making your views known to your delegates, both national and state. It is your democratic right—and responsibility.

Write your delegates, call them, see them. If they aren't responsive, tell them they'll be hearing from you at election time.



You can also go directly to the top and express your views before the AMA House's Reference Committees at either of the two annual conventions.

But it's up to you. If you have strong convictions about something that should be changed, you can be heard.

Join us. We are only what the doctors of this country want us to be. Find out more about the AMA. Send for the pamphlet, "The AMA and the American Doctor: Sharing a Common Goal." Write: Dept. DW, at the address below.

JOIN US.
WE CAN DO MUCH MORE TOGETHER.

aluminum and magnesium hydroxides with simethicone

STUART PHARMACEUTICALS | Division of ICI America Inc. | Wilmington, Del. 19899 | Pasadena, Calif. 91109

Why send him to the islets of Langerhans?

Since sulfonylureas promote the release of insulin which is lipogenic and helps transport glucose into adipose tissue...

And since many overweight patients already have normal or high levels of endogenous insulin, why not consider DBI-TD?

It lowers blood sugar without stimulating insulin secretion from the pancreas. And this may be important to the dieting diabetic.

In adult-onset, nonketotic diabetics uncontrolled by diet alone...

DBI-TD® Geigy
phenformin HCl

lowers blood sugar without raising blood insulin.

DBI® phenformin HCl
Tablets of 25 mg.
DBI-TD® phenformin HCl
Timed-Disintegration
Capsules of 50 and 100 mg.

Indications: Stable adult diabetes mellitus; sulfonylurea failures, primary and secondary; adjunct to insulin therapy of unstable diabetes mellitus.

Contraindications: Diabetes mellitus that can be regulated by diet alone; juvenile diabetes mellitus that is uncomplicated and well regulated on insulin; acute complications of diabetes mellitus (metabolic acidosis, coma, infection, gangrene); during or immediately after surgery where insulin is indispensable; severe hepatic disease; renal disease with uremia; cardiovascular collapse (shock); after disease states associated with hypoxemia.

Warnings: Use during pregnancy is to be avoided.

Precautions: 1. *Starvation Ketosis:* This must be differentiated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of relatively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state. **Do not give insulin without first checking blood and urine sugar.**
2. *Lactic Acidosis:* This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.
3. *Hypoglycemia:* Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.

Adverse Reactions: Principally gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake.

President's Letter

Freedom from Choice?

EXISTENCE WITHOUT structure is thought to be frightening for the human species. This concept prompted Erich Fromm to author his book Escape from Freedom. November, 1972, finds our country in the midst of either/or confrontations, many of which relate to our political process. Straight ticket voting may be less frequent than ever before, and from what many are saying, some choices for certain offices may not be made at all.

Unfortunately our profession has a high percentage of its members, both young and old, whose philosophy can best be summarized as "I am too busy practicing medicine to be bothered with politics (medical or party);" or "organized medicine, i.e. the establishment, does not represent my views so I will not participate."

To choose to stay outside and exercise your voting right only, to choose not to be involved in your professional society but complain about its posture, is escaping from real choice.

Real choice means a commitment, a risking of yourself and the values you hold as important. You may lose, you may be in the minority, you may find your ideals and values challenged successfully, and this can create an anxiousness most of us would like to avoid. If we can realize selfhood is not dependent on our knowledge, morals or particular ethic, but is due to the fact that *we are,* i.e. a person, a self, then the anxiety of risk taking is lessened. We can then exercise our choices, we can be free to choose real involvement in life.

Physicians are thought of as rugged individualists. If this is so, they are sure of their individualism or if you will, their self. Some I fear are instead rigid individuals who are therefore not sure of self but play the game for their own protection. I hope our profession will become stronger by gaining people sure enough of their selfhood to risk commitment to democratic processes. Will it be said we retreated into freedom from choice? Or shall we go forward to freedom of choice?

"The history of science, and in particular the history of medicine . . . is . . . the history of man's reactions to the truth, the history of the gradual revelation of truth, the history of the gradual liberation of our minds from darkness and prejudice."

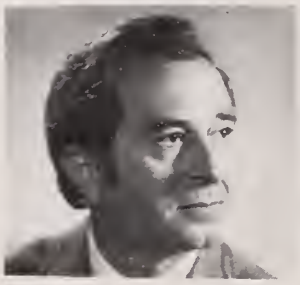
– George Sarton, from "The History of Medicine Versus the History of Art"

Are combination drug products useful in treatment involving concomitant use of two or more drugs?

Opinion

Results of a questionnaire to 7,000 physicians:

62.9%
Believe combination drug products are useful.



13.8%
Do not believe combination drug products are useful.

Are combination drug products useful in treatment involving concomitant use of two or more drugs?

Opinion & Dialogue

Doctor of Medicine

Louis Lasagna, M.D.
Professor and Chairman
Department of
Pharmacology & Toxicology
University of Rochester
School of Medicine
and Dentistry

Obviously, many drugs are given concomitantly. Whether it makes sense to combine medications in one preparation, he it capsule, tablet, or liquid, is a question that can be answered only by examining the advantages and disadvantages in the individual case.

Among the advantages is, first of all, convenience. The more medications that are taken concurrently and the more complicated the diréctions, the less likely tbe patient is to take medications accurately. From the standpoint of convenience and accuracy, and economy as well, you can make an important case for putting medications together in one preparation, as long as they are compatible.

By the same token, when you prescribe a properly tested and rational combination, you should have less worry about pharmaceutical or pharmacological compatibility – and about reasonable dosage ratios as well. Compatibility of the formulation should be demonstrated in the laboratory and clinic before the product is available for prescription—which is more than can usually be said for the physician's own spontaneous creations. And, the dosage ratios employed in rational precompounded combinations are designed to meet the needs of substantial numbers of "typical" patients.

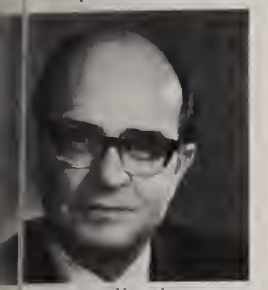
Tbere is no doubt that many "atypical" patients are to he found, and for them the prefahricated comhination must he rejected. But that hardly argues for eliminating rational comhinations from the market. Think, for example, of the problems that would arise if the components of widely accepted combinations, like the oral contraceptives and the diuretic-antihypertensives, always had to he prescribed, purchased and ingested separately.

One disadvantage that comes to mind is some doctors' unawareness of the ingredients a given comhination contains. For example, a doctor might know that a patient is allergic to aspirin hut forget that a certain analgesic mixture, which he knows only hy its trade name, contains aspirin. His prescription, then, causes considerahle discomfort, to say the least. This problem is a function of physician education, rather than of comhination therapy as such. Improving doctors' knowledge ahout all medicaments they prescribe is a problem that deserves tackling on its own.

Another accusation leveled at combination drugs is that they encourage sloppiness of diagnosis and treatment. In many cases, however, a combination may prove to be the most effective choice. A good example of the usefulness of combinations appears in a recent article in the *Journal of Chronic Diseases* on the efficacy and side effects of an antihypertensive containing three ingredients, in which the track records of the combination drug and the individual ingredients were compared. Interestingly enough, whether the drugs were given individually or together, incidence and severity of side effects were the same. But blood pressure control was invariably better when the drugs were taken in one combination tablet than when they were taken separately (in "titratable" dosage) or in two or three different tablets.

Deciding which combinations constitute rational tberapy obviously leads to a discussion of who is to determine which should be used and which should not. Realistically, I think combinations should be evaluated somewhat differently if they are old and established or new and untried.

In today's regulatory atmosphere, there is no possibility of a new combination being put on the market without a subsbantial amount of acceptable evidence in the form of controlled trials that show it to be safe and efficacious. On tbe other hand, I believe a different set of standards should apply to combination preparations that have been around for a long time. In otber words, physician acceptance over a long period should be given some weight as evidence of the efficacy and safety of these drugs.



The FDA, however, does not seem to share this attitude. It often requires, for these older products, controlled trials tbat will monopolize the time of already overtired investigators and cost a gre of money. I wisb w agree on a "gran clause" approach t rations tbat have bee for a numher of ye that have an app satisfactory track re

For example, I some of the antibiot hinations that wer off the market by th performed quite we thinking particul penicillin - strepto combinations that —especially surgi tients—were given injection. Tbis ma less discomfort for tient, less dema nurses' time, and opportunities for errors. To take preparation off the doesn't seem to b medicine, unless act age showed a great harm from tbe inj (rather than tbe use) of the combina

The point that sbo emphasized is that are both rational an tional combinations real question is, who determine wbicb is Obviously, the FDA play a major role in ing this determinati fact, I don't think avoid taking the ulti responsibility, but it enlist the help of o physicians and expe assessing the evidenc in making the ultima cision.

ake antibiotic mixtures,
source of much of the
icism generated against
combinations generally. Obviously, no one should be exposed willy-nilly to the potential side effects of two or three antibiotics when only one is needed. At the same time there are cases where it is prudent to prescribe more than one. The clinician is the judge in these circumstances, as he should be.

There is no clear definition of the word rational. Most persons, I suppose, would find it synonymous with reasonable, hut in many circumstances it may best he defined as the opinion of those in power at the moment.

Other factors govern combination therapy, not the least of which has been its broad use by practicing physicians anxious to achieve convenience in prescribing, to reduce medication error, and to save money for their patients. Combinations clearly have met the test on all three counts.

I have been impressed by studies showing that the rate of error climbs markedly with the number of medications to he taken, even with sophisticated patients. When medically justified, therefore, this factor alone supports the logic of combination therapy.

The cost argument for combinations appears to be irrefutable. In 1971, R. A. Gosselin studied the 71 combination products (excluding oral contraceptives) among the 200 most prescribed drugs. The study found that if all 71 products were discontinued, and if each ingredient in these combinations were prescribed separately, the price of medicines to patients would jump by $443.2 million on a national basis! At a time when the cost of medical care is under so much fire, it would be nonsensical to boost costs without clearly irrefutable medical reasons.

The part played by government on this question, of course, is fundamental. The FDA should play a role in determining which combinations are reasonable. That role, as defined by law and regulation, is to ensure that any medication on the market is safe and effective in line with its label claims. Certainly combinations are entitled to as much consideration as single entities—neither more nor less. So long as the addition of one drug to another does not make either less safe, or less effective, so long as they are compatible in a formulation, we have a reasonable product. It makes no sense to recommend the use of two products for certain conditions and to deny their being combined in a single form. An unhappy side effect of the problem concerns the efficacy panel discussions of many products submitted for review. The term "effective, hut" has been freely interpreted to mean "ineffective" in toto, regardless of the merit of the individual drugs. This interpretation has placed numerous useful combination products in needless jeopardy.

In reading the actual reports of the review panels, it seems clear that some of the ratings were based less on scientific research and clinical observation than on the "informed" opinions of the panelists. These "informed" opinions were accepted at face value, while the "informed" opinions of others who had used the products were rejected. All of this put combination products into a sort of scientific never-never land.

It should be kept in mind by all, government as well as others involved in our health care system, that advances in therapy are seldom made in leaps and bounds but rather by small painstaking steps—and that some of these steps have resulted from research in combination drugs as well as with single entities. Given the near-infinite biologic variation in patient response, this is hardly surprising to clinicians. It should not be to regulatory agencies either.

In the end, the practicing physician is in the best position to decide if a particular combination makes sense. Such a decision should not be made exclusively by those whose responsibility for continuing clinical care is limited. Clinicians are the best judges of efficacy because the ultimate proof of any product's effectiveness is acceptance by physicians who have observed its actions in patients over time. The corollary statement may he made about over-the-counter medicines, which would not long survive if they failed to afford the relief the user anticipates. That the antihistamine in a "cold" remedy may not *always* be necessary is no reason to proscribe the combination generally.

Opinion & Dialogue

What is your opinion, doctor?
We would welcome your comments.

Snowmobile Fatalities in Minnesota

H. PHIL GROSS, M.D.

THE FIRST SNOWMOBILE built is credited to 'arl Eliason of Saynor, Wisconsin. He put a two nd one half horse out-board motor on a toboggan n the winter of 1924-25 and used it to go hunting nd fishing. Eliason, a Wisconsin storekeeper, atented his machine and sold it to a manufacturng concern that still sells them today.

However, Leo Atherton, a 16-year-old Minneapolis youth mounted a Harley-Davidson motorcycle on a bobsled in 1913 and called the machine a "Sno-Mobile."

There is little doubt that either of these men had any idea of the tremendous popularity their nvented machine would enjoy. It is estimated here are already over one million of these machines in use in the United States, with a projected sales of 350,000 units or more this year. This is still considered minimal saturation of the market; so our statistics concerning injuries and deaths can be expected to increase for several years to come.

Most papers on the subject of snowmobiling have dealt with the injuries involved.[1-7] The site of injury is most often the lower extremity, in a young male. The driver is most often involved, either in a collision with another vehicle, or with a fixed object.

The following case serves to illustrate the narrow margin that exists between a serious "scrape" and death in some snowmobiling injuries.

Case Report

A 14-year-old boy hit a wire restraining rope on a golf course while riding his sno-mobile. Due to irregular terrain, he did not see the wire and sustained a scraping injury of the neck and chin, dislodged his dental braces, and was thrown from the sno-mobile. He was able to remount the vehicle and drive for help.

Shortly afterwards, he was examined and the previously mentioned bruising and scraping were the only obvious injury. He had a full range of motion of the cervical spine and neurological exam was negative.

Dr. Gross is a member of Orthopaedic Associates, Ltd., 1000 South Euclid, Sioux Falls, South Dakota 57105.

Anteroposterior and lateral Xrays of the cervical spine were interpreted as normal. The boy was sent home with instructions for care of skin abrasions which healed satisfactorily. He continued to complain of neck stiffness and returned six weeks later when further Xrays were obtained.

The full extent of the initial injury was then apparent. The subluxation at C2-3 now showed early healing in this altered position. Reduction with fusion was performed.

Three months later the patient's spine was solidly healed, and he was asymptomatic.

Cervical spine injuries in the snowmobile sport do not always terminate so favorably. In Minnesota last year, 16 deaths occurred,[8] of which the largest number were due to head and neck injury.

Fatal Snowmobile Accidents in Minnesota 1970-71	
Head and neck injury	8
Drowning	3
Chest injury	2
Multiple injury	3
	16 deaths

Fig. 1—Lateral view—cervical spine. Taken immediately after injury. No abnormalities seen.

Fig. 2—Anterior-posterior view—cervical spine. Taken immediately after injury. No abnormalities seen.

Fig. 3—Lateral view—cervical spine. Taken six weeks after injury. Show forward subluxation of C2-3.

Fig. 4—Anterior-posterior view—cervical spine. Three months after fusion.

Fig. 5—Lateral view—cervical spine. Three months after fusion.

The multiple injuries listed were a combination of severe head injury, crushed chest, and broken extremity.

This represents an increase in fatalities in Minnesota from 10 the previous year[5] to 16 in the year 70-71. This same trend is seen in the entire United States.

atalities in the U.S.A. Due to Snowmobile Accidents	
54	1968-69
84	1969-70
02	1970-71

Analysis of the 16 Minnesota deaths (14 males and two females) illustrated that the majority of accidents occurred in late afternoon or early evening. The average age was 32 years, with a range from four to 65 years.

New York and Michigan had the highest number of deaths, even though New York had less registered snowmobiles than Minnesota.

State	Deaths	Number of Snowmobiles
New York	18	142,000
Michigan	18	203,411
Minnesota	11	190,000
Wisconsin	6	117,000
Maine	6	43,000
	1969—70	Estimated 1971

While it is possible to count the deaths that have resulted from snowmobile accidents, a reporting system to count the lives saved by the machine has not been devised. While 95% of the machines are sold for recreational purposes, 5% are used for other functions such as law enforcement and various wild life activities. It has allowed penetration of some previously impassible areas in the winter-time. Two years ago when our area had an unprecedented large snowfall, it helped distribute food and medication to many stranded people.

From the reports reviewed, there are two factors which have a direct relationship with the fatality: speed and visibility.

Speed and visibility are closely linked, because the faster the vehicle is moving, the less reaction time is present to respond to what is visible. Although the usual speed of the snowmobile is 15-35 miles per hours, speeds exceed 100 miles per hour in racing. The newer models have increased horse power, and travel at 50 miles per hour is not unusual.

After review of the accidents and fatalities that have occurred, the following recommendations are listed.

Driver:

1. **Become familiar with your machine.**
2. **Become familiar with the terrain.**
3. **Be aware of unsafe weather conditions.**
4. **Do not explore unknown territory at night.**
5. **Do not "jump" the machine with more than one person on board.**
6. **Do not follow other vehicles too closely.**
7. **Tow only with a solid tow bar.**
8. **Wear proper attire.**
   a) **No loose clothing that can catch in gear.**
   b) **Wear helmet and goggles.**
   c) **Wear weather-proof suit. (There is one available that will keep you afloat.)**

Manufacturer:

1. **Develop an unbreakable windshield that will protect the head, face and neck.**
2. **Supply proper lighting.**
3. **Supply proper leg protection.**
4. **Supply a dead-man's* throttle that will not stick.**
5. **Continue research regarding proper ski width, suspension, and angle of attack on snow, plus better traction for control of the machine.**

*"Dead-man's" throttle is that type of throttle that will bring the machine to an idle the minute the hand is released.

Summary

A case of a cervical spine injury while snowmobiling is presented and the subject of head and neck injuries and snowmobile fatalities is reviewed. Safety suggestions for the driver and manufacturer of snowmobiles are outlined.

Malignancy in A Longstanding Colon Polyp

JAMES J. MONGE', M.D.

THE MALIGNANT POTENTIAL of adenomatous polyps of the colon is still considered controversial. Castleman[1] has stated that the probability of carcinoma arising in such a polyp is negligible. The following case is relevant.

Case Report

An obese 82-year-old man was admitted to the hospital for treatment of emphysema, myocardial ischemia with congestive heart failure and bronchopneumonia. After the patient's condition had improved surgical consultation was requested because of a tumor of the colon.

A polyp 3.5 cm. in diameter had been found in the hepatic flexure of the colon by barium enema examination seven and one-half years prior to this hospitalization (Figure 1). Because of his age and fragile general health the patient's physician had not recommended surgical excision of the polyp. A barium enema examination two years later showed the polyp unchanged in form and size, but radiologic examination four years after discovery showed the polyp to have enlarged to 5 cm. in diameter. Over the next two years no further change in the size was seen on annual Xrays, but the most recent barium enema, performed during the present hospitalization, demonstrated an annular carcinoma of the colon at the exact site of the previously seen polypoid tumor (Figures 2 and 3).

Laparotomy confirmed the presence of an adenocarcinoma of the right colon with a large metastasis in the central portion of the liver. A palliative right hemicolectomy was performed. The ulcerated tumor measured four cm. in length and involved the full circumference of the colon. No other polyps were found.

The patient returned home but later developed cachexia, hepatomegaly, and icterus, and expired five months after operation.

Pulmonary and adrenal metastases were found on necropsy examination. The liver, in addition to a large central mass of tumor measuring 13 X 10 X 10 cm., was diffusely involved with nodules of metastatic carcinoma measuring up to 2.5 cm. in diameter. An acute duodenal ulcer, bilateral pyelonephritis, coronary atherosclerosis with myocardial scarring, pulmonary emphysema, and severe bronchopneumonia were also found.

Dr. Monge' is in the Department of Surgery, The Duluth Clinic, Duluth, Minnesota.

See editorial, page 1014.

Fig. 1—Initial barium enema examination showing a large polyp in the hepatic flexure of the colon, seven and one-half years prior to right hemicolectomy.

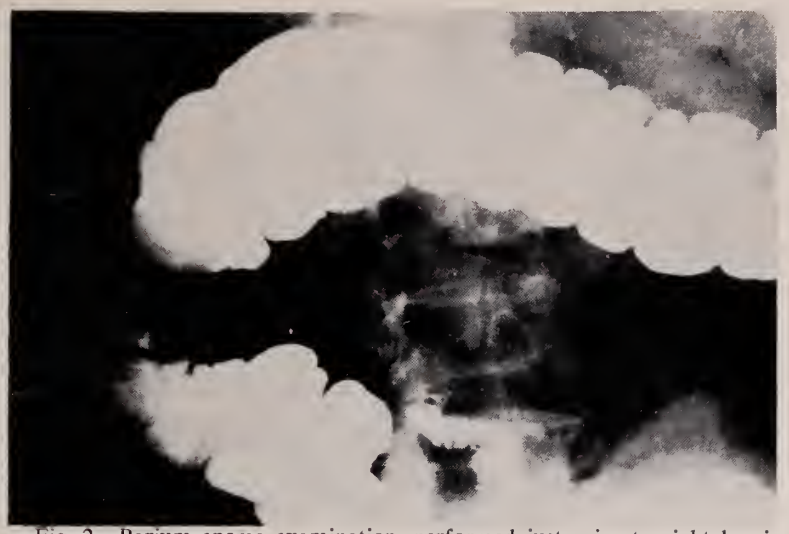

Fig. 2—Barium enema examination, performed just prior to right hemicolectomy, demonstrating an annular adenocarcinoma of the colon at the site of the polyp shown in Figure 1.

Comment

At least 18 case reports have been published in which patients, within two to 19 years, have developed carcinoma at the site of a previously demonstrated, but not removed, colon polyp.[2] It has also been shown that carcinoma arising in the tip of an adenoma can be an early anatomical stage of clinical cancer; in at least 14 instances cited, lymph node, hepatic or pulmonary metastases have been associated with such a lesion.[3,4]

Fig. 3—Spot film of the annular adenocarcinoma of the colon.

The tumor found in this case enlarged very slowly during the first six years that it was followed, only doubling in size while retaining a polypoid appearance. Rapid growth during the year prior to surgery culminated in an obvious annular carcinoma. One may postulate that the tumor was a slow growing adenocarcinoma from its inception. On the other hand, the abrupt change in growth rate and appearance suggests that this was a benign polyp of the colon that became malignant.

Many adenocarcinomas of the colon may arise *de novo* from the mucosa or from villous polyps. However, since small polypoid carcinomas cannot be differentiated radiographically from benign polyps, and since adenomatous polyps may become cancerous, the surgeons at the Clinic continue to recommend removal of polyps of the colon which are sessile or are greater than 1.5 cm. in diameter (as well as all those within reach of the proctoscope). The polyp is oriented for central perpendicular sectioning; if frozen section examination discloses invasive carcinoma, a bowel resection is performed.

Congenital Coronary Arterial Venous Fistula

Repair

JOSEPH C. KISER, M.D. AND ROBERT SCHULTZ, M.D.

SINCE FIRST DESCRIBED by Drause in 1885, congenital fistula of the coronary arteries has been reported nearly 200 times. The fistula is most commonly between the right coronary artery and the right heart. Rarely the left coronary artery and the left ventricle are involved. A variety of surgical procedures have been described for treatment of this lesion. Although the methods of treatment previously described have met with varying degrees of success, we believe that total excision of the fistula and repair using a vein graft from the aorta to the distal normal coronary involved represents a new and better method of treatment. The following is a case report of a congenital fistula of the right coronary artery communicating with the pulmonary artery, coronary sinus and right ventricle.

Address requests for reprints to: Joseph C. Kiser, M.D., 1012 Metropolitan Medical Bldg., 825 South 8th Street, Minneapolis, Minnesota 55404.

Case Report

This 35-year-old-white female was initially noted have a continuous murmur in the left second interspa on a routine obstetrical visit. She was asymptomatic. was the impression of the consulting cardiologist that th represented a patent ductus arteriosus without seve hemodynamic derangement. Her blood pressure w 120/80. The first and second heart sounds were norm There was a continuous murmur which was accentuate just prior to the second heart sound and advanced int the early part of diastole. It was believed to be a typic patent ductus murmur in both its location and intensit A thoracic aortogram was obtained which revealed small tortuous patent ductus arising from the inner borde of the distal aortic arch. The electrocardiogram wa normal. On May 3, 1971 the patent ductus was divide through a posteriolateral thoracotomy. It was approx mately four mm. in diameter, long and tortuous. Afte dividing the patent ductus, it was noted that the contin uous thrill over the pulmonary artery was still present The pericardium was opened. A markedly enlarged an tortuous right coronary artery was found. The thrill wa

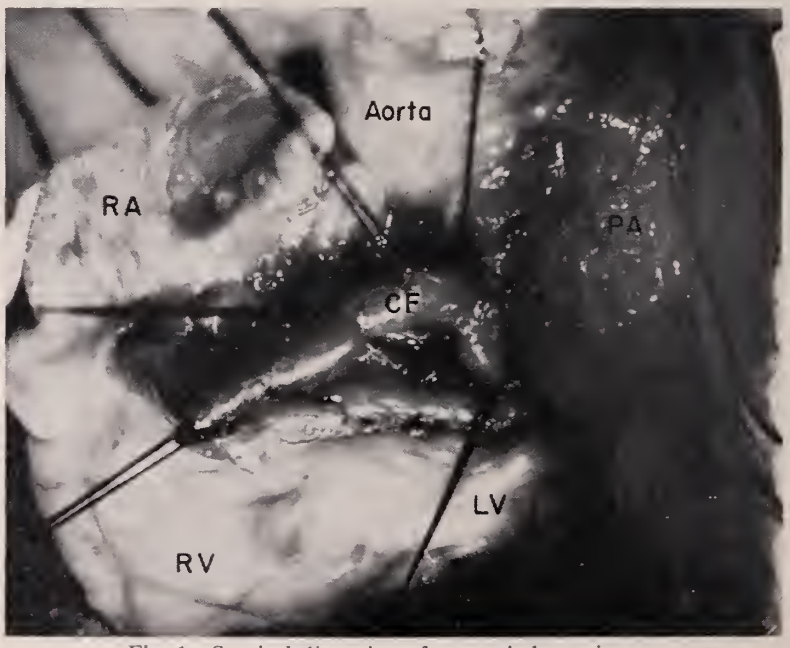

Fig. 1—Surgical dissection of congenital arteriovenous fistula. CF—arteriovenous fistula involving right coronary system. PA—pulmonary artery. RV—right ventricle, LV—left ventricle. Connection of fistula with aorta is rudimentary.

noted to be most intense at the root of the main pulmonary artery. The chest was closed in the usual fashion and her postoperative course was uncomplicated. On May 7 a selective coronary angiogram was obtained. The left coronary demonstrated an extremely large left common with a large tortuous left anterior descending, left circumflex and left marginal branches. There was an extensive anastomotic network from the circumflex to the marginal branches which filled the tortuous and aneurysmal right coronary artery retrograde. The proximal end drained into the pulmonary artery and coronary sinus. No right coronary ostium was present in the right aortic sinus. The left ventricular end diastolic pressure was slightly elevated. The conclusion of this study was that there was a large left coronary artery with collateral filling of the entire right coronary artery via the left marginal and circumflex branches. The anomalous origin of the right coronary artery was from the pulmonary artery. She was discharged from the hospital and re-admitted on June 29, 1971. At that time, her heart was explored through a median sternotomy. Extracorporeal circulation was employed. When the heart was examined, there was noted to be a continuous thrill over the main pulmonary artery. There was a large caliber tortuous thin walled structure occupying the right atrioventricular sulcus. It appeared to arise from the root of the pulmonary artery. There was a rudimentary connection with the root of the aorta. The right coronary artery was completely dissected and 00 silk ligatures were passed around all branches to the right coronary artery down to the junction of this vessel with the posterior-descending coronary artery. These vessels were dilated, tortuous and thin walled. It was obvious that the flow was in a retrograde manner through the fistulous vessel into the pulmonary artery. After completely dissecting this vessel (Figure 1), we were convinced that the entire right system filled from the left coronary artery by way of the posterior descending into the right main coronary artery since there was a large left to right shunt present. After exposing all branches of this fistula, it was excised and the individual branches ligated. The main entrance point into the pulmonary artery was also ligated. From the anatomic appearance of this anomalous vessel, it was entirely possible that there were multiple communications with other chambers of the heart. After the anomalous vessel had been completely dissected free and its branches ligated, a saphenous vein graft was utilized to reconstruct the right coronary system (Figure 2). The proximal anastomosis was made to the ascending aorta and distally the vein graft was anastomosed to the posterior descending coronary artery. Bypass was gradually discontinued and hemodynamics were immediately satisfactory. Flow was measured in the saphenous vein graft and it was found to be 50 cc. per min. Her postoperative course was uncomplicated and she was discharged from the hospital on the ninth postoperative day. She has remained asymptomatic.

Discussion

The diagnosis of coronary artery fistula may be somewhat difficult clinically particularly when the main fistula drains into the pulmonary artery. As in this case, the clinical findings are indistinguishable from patent ductus arteriosus. Indeed, approximately 20 percent of patients with coronary artery fistula have other cardiac anomalies.[1] In

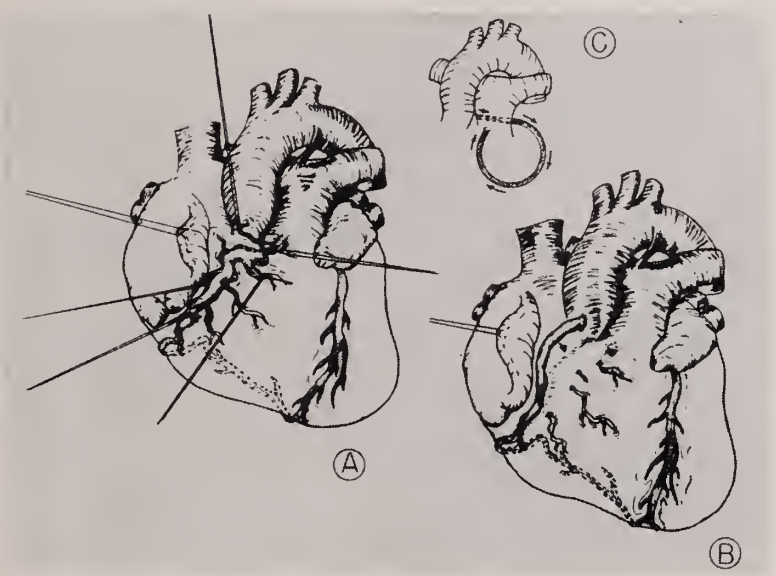

Fig. 2—Diagramatic sketches of a congenital coronary arteriovenous fistula and its repair. (A) Large fistula of right coronary system connecting with the posterior descending coronary artery and draining into the main pulmonary artery. (B) Excision of the fistula and reconstruction of the right coronary arterial system by anastomosing a saphenous vein graft between the posterior descending branch of the right coronary artery and the aorta. (C) Diagram indicating the left to right shunt between the left coronary artery and the pulmonary artery via the coronary arteriovenous fistula.

the adult variety of the lesion, patent ductus is the most common associated malformation. Depending upon which chamber the fistula enters, the location of the murmur may be atypical for patent ductus arteriosus. Although myocardial ischemia associated with this lesion is an uncommon feature, occasionally myocardial necrosis has followed simple ligation of the fistula. The majority of these patients with the adult form of the disease are symptomatic. Bacterial endocarditis has been noted to occur in 10 percent and may be the first clue to the anomaly. Although the aneurysm is an extremely thin walled vessel, spontaneous rupture has been rare. Derangement of hemodynamics varies according to the volume of the left to right shunt. Chest Xray is not diagnostic although a few unusual cardiac silhouettes have been reported due to aneurysmal dilatation of the involved coronary. Electrocardiography has not proved helpful in isolating these cases. Probably the greatest advance in localizing the lesion is the result of refinement in technique of coronary angiography in recent years. A number of surgical approaches have been suggested for treatment of coronary artery fistula. Biorck and Crafoord[2] in 1947 successfully closed a fistula by ligating the involved artery. Since that time, a number of patients have been treated in this manner. On occasion, this has resulted in distal ischemia and myocardial necrosis. It has become apparent that preserving the continuity of the coronary artery or coronary fistula and its distal blood supply is important. In 1962, Cooley[3] employed interlocking mattress sutures behind the coronary artery to accomplish this. However, recurrent fistula formation has been reported using both of these techniques. More recently, Gross and McNamara[1] in 1968 favored closure of the fistula through a ventriculotomy. Each of these techniques has the disadvantage of leaving an abnormal thin walled vessel in place which carries the risk of rupture and recurrence of the fistula. Indeed, thrombosis and late rupture have been reported following the ligation procedure. Although the literature is not clear on the possibility of multiple points of communication with the various chambers of the heart, it would appear from review and from our case that multiple communications with the various chambers may occur. For these reasons, we believe that total excision of the anomalous vessel and reconstruction using a vein graft from the aorta to the distal normal portion of the involved coronary system is an improved method for dealing with this problem.

Summary

Coronary artery fistula is an uncommon congenital cardiac malformation. Advances in coronary angiography as well as vein by-pass techniques which have been used in treating other types of coronary artery lesions make it possible to treat coronary artery fistula by total excision and reconstruction using a vein graft. Recurrence of the fistula following this procedure is unlikely. It also affords re-establishment of a double coronary artery circulation in a nearly normal pathway.

Permanent Transvenous Sequential Atrioventricular Pacing

Problems in Its Application

AMADO S. SANTOS, M.D., MARTIN WYNYARD, M.D. AND MARTIN M. BLACK, M.D.

PERMANENT TRANSVENOUS sequential atrioventricular (A-V) pacing requires a safe, simple and stable atrial electrode. American Optical Corporation's J-shaped electrode best fulfills these criteria (Figure 1).

The following case report illustrates the successful use of such a pacer where a temporary ventricular demand pacer proved to be a failure. The pacer used was a bifocal atrioventricular demand type from the American Optical Corporation. It consists of two units in a single package, (Figure 2): A conventional QRS inhibited ventricular pacer and a QRS inhibited atrial pacer which share a single QRS detector. To understand its mechanism two terminologies require clarification: Atrial escape interval and ventricular escape interval. Both intervals are timed from either a sensed or an induced R wave (Figure 3).

If the patient's normal R-R wave interval is shorter than the pacer's atrial escape interval, the pacer will be totally dormant. If the patient's normal R-R wave interval is longer than the pacer's atrial escape interval, but shorter than the pacer's ventricular escape interval, the pacer will stimulate the atria and be inhibited in the ven-

tricles. If the patient's normal R-R wave interval is longer than the pacer's ventricular escape interval, the pacer will stimulate both the atria and the ventricles in sequence.

Techniques Involved:

1. Local anesthesia with the anesthesia department in standby.
2. Atrial electrode hooked into the right atrial appendage preferentially with the tip turned to the right (Figure 4).
3. EKG monitoring with a battery operated unit which is directly connected to the endocardial electrodes during positioning.

Case Report

An 80-year-old woman admitted to the hospital in September, 1971, with an acute anterior myocardial infarction and whose hospital course was complicated by various arrhythmias as well as a refractory congestive heart failure.

The patient has been a diabetic for 15 years. She has had severe hypertension in the past. Six years ago she was found to have splenomegaly. In 1970 the spleen became massively enlarged associated with hypersplenism, pleural effusion, and massive ascites. A splenoportogram was normal. The ascitic fluid was evacuated by cannulation of the peritoneal cavity and drainage into an apparatus allowing direct retransfusion into the venous system (a total of 23 bags in four days were thus autotransfused). She developed multifocal atrial tachycardia, sinus bradycardia, junctional (A-V) rhythms and other types of arrhythmias. In spite of pharmacological agents the bradycardia persisted. A temporary pervenous ventricular demand pacer had to be inserted prior to a successful splenectomy (1380 gm) and an abrasion hepatopexy in November, 1970. The patient did well after surgery and was sent home in December, 1970, without a pacer.

Physical examination on the present admission showed normal vital signs. The neck veins were flat, the lungs clear, and the heart rate was 100 per minute with frequent extrasystoles. No murmur or gallop was heard. There was no ascites, hepatomegaly, or pedal edema.

The initial electrocardiogram showed sinus rhythm at 100 per minute, normal A-V conduction, complete right bundle branch block, few P.V.C.'s and deep Q waves with S-T elevation in V1 to V4 consistent with an acute anterior myocardial infarction. Soon after admission to

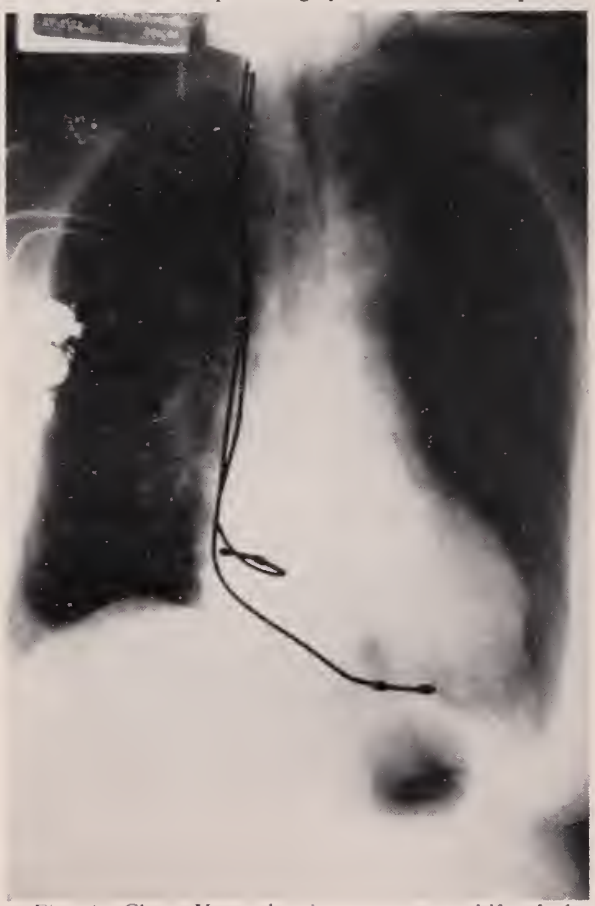

Fig. 4—Chest Xray showing permanent bifocal demand pacemaker and electrodes after implantation. Note tip of atrial electrode pointing to the right. The electrodes are re-touched to achieve contrast. Considerable clearing of lung fields when compared with ventricular pacing alone (Figure 6).

Fig. 5—Right lateral chest film after implantation of permanent bifocal demand pacemaker. (Electrodes retouched.)

the coronary care unit the patient developed runs of ventricular tachycardia which responded to Lidocaine. Two days later she developed supraventricular tachycardia which changed to sinus bradycardia and atrial standstill after parenteral Digoxin. The patient's condition deteriorated rapidly. A temporary pervenous ventricular demand pacemaker was inserted in September, 1971. The patient continued to have various arrhythmias including supraventricular tachycardia, junctional (A-V) rhythm and refractory congestive heart failure in spite of pharmacologic agents. (Figure 6). In November, 1971, a permanent transvenous sequential A-V pacer replaced the ventricular pacer. (Figures 4 and 5). The patient gradually diuresed and improved clinically.

Fig. 6—Chest Xray prior to sequential pacing showing temporary transvenous ventricular electrode. (Electrode re-touched.) Passed via a left superior vena cava remnant through the oblique vein of the heart into the coronary sinus. Note persistent pulmonary congestion.

Comment

Atrioventricular pacing has certain physiologic advantages in specific clinical settings over ventricular pacing. With A-V pacing the atrial contribution to the ventricular end diastolic volume is retained. Studies have shown that sequential A-V pacing can augment the cardiac output by as much as 24% and that arterial pressure rises while venous pressure falls. In demand sequential atrioventricular pacing the machine senses the ventricular endocardial electrogram and paces the atrium and ventricle sequentially, (Figure 7). A comparison of the various types of A-V pacing is shown in the Table.

With the use of a J-shaped atrial electrode positioned in the right atrial appendage, reliable permanent pacing with a transvenous electrode is now available. (Turning the tip of the electrode

TABLE

DIFFERENCE BETWEEN THREE MODALITIES OF A-V PACING

P-wave Triggered	A-V Sequential-Continuous	Bifocal Demand or A-V Sequential-QRS Inhibited
Monitors P-waves	No Monitoring	Monitors QRS Complexes
P-waves Control Ventricular Stimulation no Atrial Stimulation Available	Stimulation is Not Affected by the Intrinsic Cardiac Activity	QRS Complexes Control Both Atrial and Ventricular Stimulation
Stimulation is Delivered to the Ventricles Continuously	Stimulation is Delivered Both to the Atria and Ventricles Continuously	Stimulation May Be: a. Totally Absent b. Delivered only to the Atria c. Delivered both to the Atria and Ventricles
Useful for A-V Block With Normal Atrial Activity	Used Mainly for Temporary Pacing	Useful for Atrial Bradycardia With Intermittent A-V Block

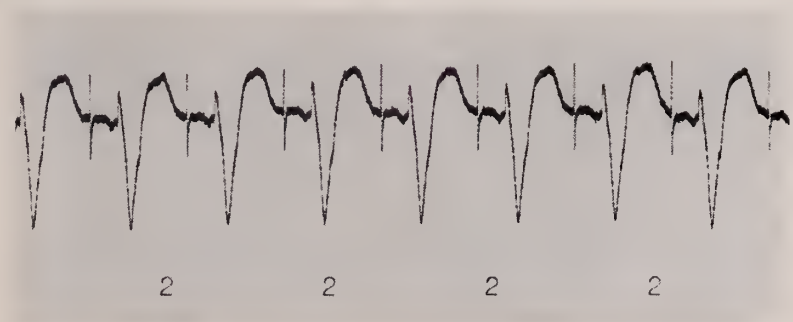

Fig. 7—EKG tracing with bifocal demand pacemaker during A-V sequential stimulation.

to the right appears to increase the stability of the electrode.) In this particular case with a sinus bradycardia we were able to set the pacer rate at a more economical level of 85 per minute. Although we did not measure the cardiac output, the patient's clinical condition including the previously refractory congestive heart failure which developed when a temporary ventricular demand pacer was in place, improved significantly after the insertion of the permanent sequential AV pacer.

An interesting diagnostic tachycardia developed two weeks after the A-V pacer was implanted (Figure 8). The questions of endocardial electrode displacement or pacer failure were ruled out by chest Xray and by activating the pacer's reed switch with an external magnet respectively. With a very short interval of 0.04 seconds between the pacer atrial spike and the succeeding QRS the possibility of accelerated A-V conduction was considered. However, the pattern is best explained by nodal (A-V) rhythm with the patient's own R-R wave interval (0.5 seconds) just slightly longer than the pacer's atrial escape interval (0.46 seconds) but shorter than the pacer's ventricular escape interval (0.71 seconds). Therefore, each QRS is followed by an atrial pacer spike 0.46 seconds later. The patient reverted spontaneously to sequential pacing after two hours.

Although the follow-up on this single case is not adequate to establish its longterm value, we have shown in this instance sequential A-V pacing did improve cardiac function from that accomplished by ventricular pacing alone.

Summary

The successful use of a permanent sequential A-V pacer in a patient with refractory congestive heart failure and rhythm disturbances where a previous temporary ventricular pacer failed, and technical points in electrode placement and interpretation of an apparent abnormal pacing sequence were discussed.

Acknowledgment

We would like to express our sincere appreciation to Mr. Jason A. Sholder, Manager of Pacemaker Products, Medical Division, American Optical Corporation for his help in the insertion of this pacemaker and the suggestion for atrial electrode placement.

The Flora and Fauna of Hernial Sacs

A Plea for Routine Histologic Examination

LUIS H. TOLEDO-PEREYRA, M.D. AND PATRICK C. J. WARD, M.D.

A NUMBER OF ABDOMINAL and pelvic organs occasionally find their way into hernial sacs. These include bladder, appendix, tubes and ovaries.[5] Two cases of ectopic pregnancy have now been reported in such a setting.[5,22] Occasionally, unsuspected cancer may be discovered on gross or microscopic examination of a hernial sac.[8] Splenic tissue is also intermittently found in scrotal hernias,[23] and in this location represents either continuous or discontinuous splenogonadal fusion. This anomaly apparently occurs only on the left side.[19,23] Rarely, endometriosis may present for the first time in hernial sacs.[17,18] Finally, the occurrence of adrenal rests in the hernial sacs of children, although frequently noted at surgery, has been only occasionally documented.[9,10]

Because of the low yield of significant pathology in hernial sac tissue, pathologists in some instances limit examination of the surgically removed hernial sac wall to documentation by measurement and cursory macroscopic description. Over a period of 16 months at Mount Sinai Hospital, Minneapolis, a 300 bed general hospital, histologic examination of 212 consecutive hernial sacs yielded three instances of disease or ectopia, all of which were unsuspected prior to surgery and two of which were unsuspected even on gross examination.

Case Reports

Case 1

A three-month-old boy was admitted for repair of bilateral inguinal herniae. A hydrocele had been noted on the right at birth. Subsequently, an intermittent fullness of the sac suggested patency of the processus vaginalis. Shortly before admission, a hernia developed above the hydrocele in the right inguinal canal. A hernia was also noted on the left side. The pre-operative diagnosis was bilateral indirect inguinal herniae with communicating hydrocele on the right. In August, 1970, a bilateral inguinal herniorrhaphy and right hydrocelectomy were performed. While grossly unremarkable, the hernial sacs were routinely sectioned and a thin, cord-like spleen, 1.8 x 0.4 x 0.3 cm. was found on the left side (Figure 1). No testicular tissue was noted histologically. The postoperative phase was unremarkable.

Case 2

A 23-year-old woman was admitted for repair of a suprapubic ventral hernia. The patient had a history of two previous Caesareans done through a Pfannenstiel incision and for the five or six months prior to admission had had pain and a mass in the midline of the lower abdomen. The pre-operative diagnosis was ventral hernia. At surgery incarcerated omental tissue was found in the hernia which was in the line of previous incisions. This was excised and the defect in the fascia repaired by a Mayo procedure. Microscopic examination of the hernia sac revealed mural endometriosis (Figure 2). The patient's

postoperative course was uneventful.

Case 3

A 17-month-old boy was admitted for a right inguinal herniorrhaphy. The inguinal hernia was diagnosed at the age of two months and had not given rise to problems until five weeks before the present admission when it incarcerated. This was treated conservatively because of an intercurrent upper respiratory infection and reduced spontaneously. On re-admission for elective surgery, both external inguinal rings were found widely patent. The testes were in the scrotum. Both inguinal areas were explored and a right inguinal herniorrhaphy was performed. A small yellow nodule suggesting an adrenal rest was noted above the testis on the left and was removed with the hernia sac. The gross impression of adrenal rest was confirmed histologically (Figure 3). The recovery was uneventful.

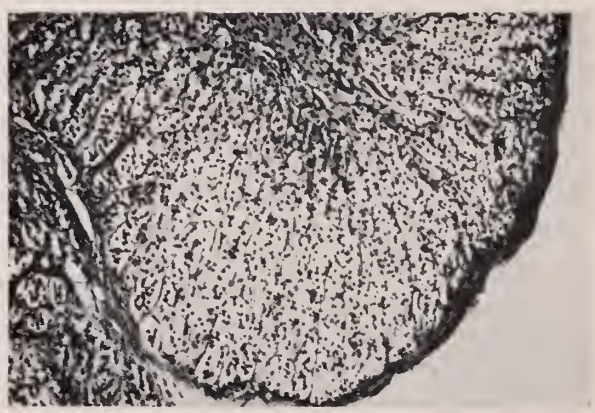

Fig. 3—Adrenal cortical tissue x 1300.

Splenogonadal Fusion

Splenogonadal fusion was first described by Bocstrom in 1883.[15] Watson reviewed the literature in 1968[23] and recorded 52 cases. The anomaly has been described by Sieber[19] as transperitoneal extension of the lower pole of the spleen through a hernial sac and fusion to the normally descended left testicle. There are at least two theories as to embryogenesis. Since the splenic anlage in the dorsal mesogastrium is opposite the genital anlage in the six weeks old embryo, adhesions between the two could account for the subsequent trailing of splenic tissue behind the descending testicle.[20] An alternate theory relates the organ association to the origin of the left spermatic artery from the splenic artery.[13]

The anomaly is either continuous in which case a cord of splenic or fibrous tissue extends from the spleen to the gonad or discontinuous in which case the splenic tissue shows no connection with the main spleen. Of the 52 cases reviewed by Watson,[23] the age range was from birth to 69 years and only four cases were in females; 29 were continuous, 19 discontinuous, and four unclassified. Concomitant birth defects included peromelus and micrognathia. Of the 38 cases diagnosed at operation, 16 had indirect inguinal herniae. All 52 cases occurred on the left side.

This lesion should be distinguished from the accessory spleen, a commonly encountered entity with an incidence ranging from 11 to 35% in various autopsy series.[24] The incidence of accessory spleen is higher when splenic disease is present in youth. The accessory spleen may be found virtually anywhere under the diaphragm and becomes important in splenectomy for a hematological disorder. Accessory splenic tissue may continue to function after splenectomy.

Finally, the lesion should be distinguished from splenosis, a condition in which splenic tissue may be found in abnormal locations (even in the thorax[1]) as a result of trauma[8] or, very rarely, of surgery.[21] Seventy cases have been reported in the world literature.[24] Most have been diagnosed within ten years of traumatic rupture of the spleen although intervals of five months to 32 years have been described. The splenic nodules implanted on peritoneal or visceral surfaces range from a few millimeters to 2-3 cm. in diameter, and there is some evidence of function.[24]

Our case is probably an example of discontinuous splenogonadal fusion because no communicating cord was found. However, such a cord containing splenic tissue might have been overlooked.

Endometriosis

Whereas endometriosis of the umbilicus and of laparotomy scars has been reported frequently, it has rarely been found in a hernia sac.

The first association between inguinal hernia and endometriosis was noted in 1916 by Cullen[3] who reported an adenomyoma of the round ligament fused with incarcerated omentum in an inguinal hernia. In 1926 Sampson[16] reported a case of endometriosis in the sac of a right inguinal hernia associated with pelvic peritoneal endometriosis and an endometrial cyst of the ovary. A further case was reported by Christopher[2] a year later. At the bottom of an oblique right inguinal hernia was a firm fibrous swelling 5 x 4 x 4 cm. which was incorporated into the sac wall. Histologically, this was shown to be endometriosis. Masson in 1945[11] while reviewing 2,686 cases of endometriosis noted two cases with involvement of femoral hernial sacs. Moore in 1957[12] de-

scribed a case in which endometriosis was present in inguinal hernial sacs on both sides, associated with extensive pelvic endometriosis. Serment et al. in 1967[18] reviewed five cases in the literature to which they added another. Two clinical features of interest were cyclic inguinal swelling and pain.

Not all cases of inguinal endometriosis imply hernial sac involvement. Endometriosis may involve lymph nodes in this region.[4] Dormandy in 1956[4] described three cases of extraperitoneal inguinal endometriosis in which, although hernial sacs were present, careful gross and microscopic examination revealed no continuity between the intact peritoneum and the endometriomata. None of the three cases showed involvement of the round ligament. Some cases of inguinal endometriosis, however, are localized to the extraperitoneal portion of the round ligament. Jimenez and Miles in 1960[7] in a review of 16 such cases in the literature pointed out that it was impossible to be sure in some cases whether the lesion represented primary involvement of the round ligament or extension from co-existing hernia sac wall. To these 16 cases, the authors added four further cases of endometriosis of the round ligament presenting as inguinal masses.

Endometriosis presenting in laparotomy scars following pelvic surgery is well known. Its occurrence in a hernial sac is rare and the sequence of events leading to the detection of endometriosis of a post Caesarian ventral hernial sac is distinctly unusual. Gross examination of the specimen would have failed to detect the lesion.

Adrenal Rests

Little has been written on the incidence of adrenal rests in the walls of hernial sacs. In 1919 MacLennan[9] reported small nodules of adrenal rest tissue less than ⅛ inch in diameter in the walls of seven hernial sacs in a series of 700 consecutive herniorrhaphies on children. One of these was lost to study so that the incidence was somewhat less than 1%. All cases were in males, but only 40 of the 700 hernia repairs were in females, making an analysis of sex distribution tenuous. In a subsequent extension of this study in 1922,[10] MacLennan found a total of 18 cases in 1,038 operations on 978 children for hernia. Potter[14] currently describes adrenal rests as occurring quite frequently throughout the peritoneum in infancy, but makes no reference to incidence in hernia sacs.

Although the finding of adrenal rest tissue in a hernial sac wall is of little clinical significance, it lends weight to the contention that all hernial sacs should be examined microscopically in quest of occult pathology.

Summary

Routine microscopic examination yielded three cases with significant pathology in 212 consecutive hernial sacs removed within a 16 month period in a 300 bed general hospital. Two lesions were unsuspected on macroscopic examination. Since subtle lesions may be overlooked both at surgery and on gross inspection, microscopic examination should be carried out on all hernial sacs.

Acknowledgments

The authors wish to acknowledge the kindness of Drs. Norman Bloom, Bernard J. Spencer, and John Waldron, all of Mount Sinai Hospital, Minneapolis, in individually contributing the above cases, and thank Miss Carolyn McNiece for providing secretarial assistance.

Cervical Disk Disease with Neural Compression

Anterior Surgical Approach

ALBERT L. RHOTON, JR., M.D. AND EDWARD D. HENDERSON, M.D.

SINCE THE PATHOLOGIC process in cervical disk disease originates anteriorly to the cervical roots and spinal cord, it is not surprising that anterior operations have been developed to remove the offending ventral elements directly.[1,2] Nor is it surprising that Mayfield[3] was able to report that the spinal cord and nerve root deficit had not been aggravated in any of 217 patients operated on by the anterior approach: retraction of the spinal cord or nerve root is not necessary to reach the pathologic process by the anterior approach, as it is by the posterior approach. He also noted that after the anterior approach the postoperative course was less painful, because the approach is through soft-tissue fascial planes rather than through posterior neck muscles and because the offending diseased disk is removed and the space realigned and immobilized during the operative procedure.[3] Rosomoff and Rossmann[4] stated that this immobilization prevents further compressive changes in ligaments and apophyseal joints posteriorly and prevents recurrence of disk disease anteriorly. The anterior operation is done with the patient supine, thus avoiding the risk of hypotension and air emboli that exists with the posterior operation, which is done with the patient sitting.

Because of these advantages, five years ago we began doing anterior operations on selected patients who had neural compression from cervical disk disease. Although there are several types of anterior operative approaches, we selected the Cloward technique for patients with neural compression because it gives a better exposure of the spinal canal and the foramen anterior to the nerve roots. The operation is done through a 4- to 5-cm transverse incision made in a skin crease on the anterior neck (Figure 1). The anterior surface of the vertebrae is exposed through the soft-tissue plane between the esophagus and trachea medially, and the carotid sheath laterally. In our 48 cases, there has not been any injury to either of these structures.

After identifying the appropriate disk space with a roentgenogram, the disk is removed (Figure 1). Using a drill ½ inch in diameter, an opening centered at the interspace is extended posteriorly to within a few millimeters of the posterior longitudinal ligament. The last few millimeters of bone in front of the ligament are removed with a small air drill. If the main disorder is a midline ridge or disk, the opening is centered in the middle third of the lateral width of the space, but if the disorder is located laterally, the opening is made off the midline directly in front of the disk deformity.

Can the lateral extent of the intraforaminal portion of the nerve root be decompressed as well by the anterior as by the posterior approach? Raynor and Kingman[5] have shown in cadavers that "the lateral extent afforded by removal of discal material and osteophytes by the anterior approach extends well beyond the point where the root turns ventrolaterally to enter its foramen and is considerably greater than can be accomplished by approaching the nerve posteriorly." After the offending lesion has been removed, a ⅝-inch diameter dowel of iliac bone 1.5 cm long is fitted into the bony opening adjoining the interspace. The bone plug is slightly larger than the bony opening, and this discrepancy restores the interspace height frequently lost with disk degeneration. Cloward[1] has devised an ingenious set of instruments for making the bony opening and obtaining the bone graft from the iliac crest; they ensure that the bone plug fits snugly into the bony

opening so that the space is immobilized once it is in place.

Results

In the last five years we have performed anterior operations on 48 patients for cervical root or cord compression. The anterior operation was the first or primary operation done to relieve the neural syndrome in 40 patients, and was done on another eight patients after a posterior operation had failed to give the desired relief. Patients ranged in age from 33 to 75 years. One patient was below 40 and one above 70. The numbers in the fifth, sixth, and seventh decades were 17, 20, and nine, respectively.

The results were much better in the group on which the anterior procedure was primary, and this group will be reviewed first. Of the 40 operations, 34 were for root compression and six for cord compression. Seventeen of the root lesions were caused by soft disk herniations and 17 by foraminal osteophytes alone or associated with soft disk protrusions. One patient had a C-5 and one a C-8 root lesion; the remainder of the root lesions were nearly equally divided between the C-6 and the C-7 roots. All patients who had root lesions were free of pain at the time of dismissal from the hospital and only one patient is known to have had a recurrence of pain later; this gradually subsided after the patient wore a cervical collar for a brief period. To ensure that the fusion

This cross section of cord and spine at midcervical region shows intraforaminal, dorsolateral, and midline osteophytes. *(C)* Same cross section as in *B*, showing bony opening into spinal canal which adjoins disk space; crosshatches show area of bone that can be removed to decompress cord and nerve roots. *(D)* Anterior view of spine showing the half-inch diameter opening in vertebra adjoining the disk space. *(E)* Bone plug fitted into opening; since plug is ⅝ inch in diameter and bone opening is half inch, when it is inserted interspace height is restored.

was solid, all patients had lateral and anteroposterior roentgenograms. in flexion and extension, six to eight weeks after surgery. The six patients who had cord compression (Figure 2) preoperatively did not have any increased deficit after surgery; four patients improved and two did not. Regardless of whether an anterior or posterior operation is to be done, all patients who have cord compression are told, preoperatively, they should be satisfied with the results of surgery if it prevents a further progression of their neurologic deficit.

Forty-one of the 48 patients had only one space fused (Figure 3); two spaces were fused in five patients and three in two patients. Fusion was done only at the level of neural compression and multilevel fusions were done only because there was evidence of neural compression at several levels on neurologic examination or on the myelogram.

The results have been less satisfactory in the eight patients who were operated on by the anterior approach after failure of a posterior operation at this institution or elsewhere. Although the deficit was not aggravated by the anterior operation in any of these patients, only three of seven who had cervical radiculopathy obtained satisfactory pain relief and the one patient with cord compression did not improve. Most of these patients had foraminal osteophytes, and after the posterior operation they were left with a constant ache and dysesthesia in the arm that was usually associated with a persistent root deficit. One patient in this group was found subsequently to have a neurofibrosarcoma of the brachial plexus; as expected, this operation failed to relieve the pain.

There were no permanent complications in this group of 48 patients nor was the neurologic deficit increased after surgery in any patient. Two had transient unilateral vocal cord paresis which had disappeared six weeks after surgery. The only other complications were saphenous phlebitis in one patient and infection at the iliac-crest donor site in another.

Discussion

Seventeen posterior-approach operations for cervical disk disease were also done by one author (A.L.R.) while this series of 48 anterior operations was in progress, and consequently patients having both types of operation were on the neuro-

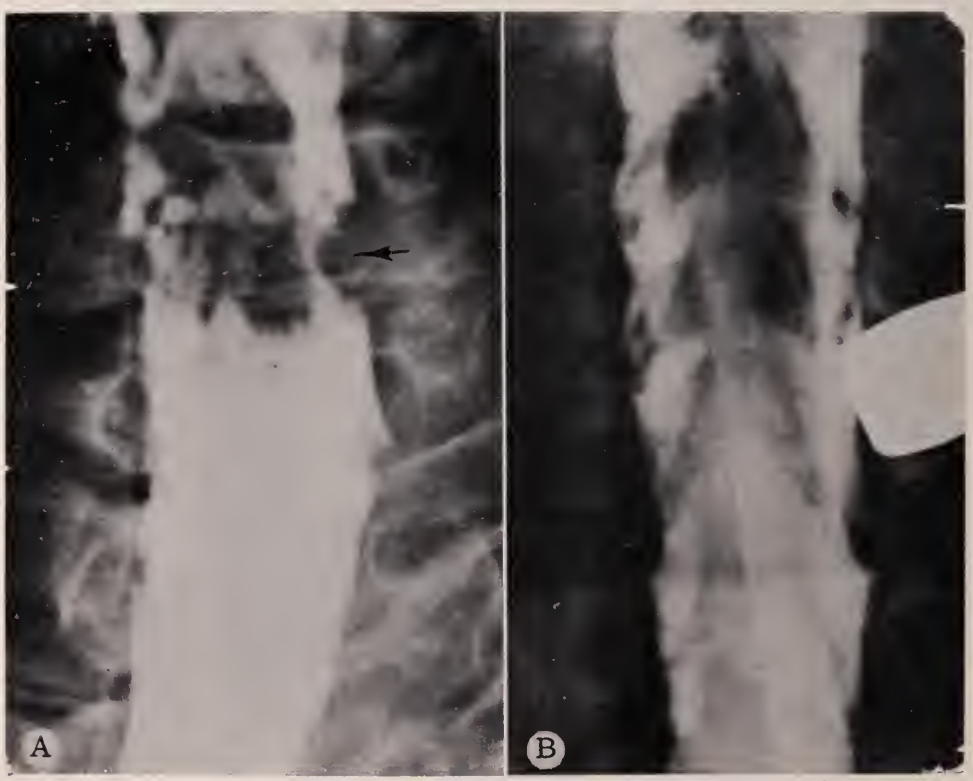

Fig. 2—*(A)* Anteroposterior view of Pantopaque myelogram of cervical spine in patient with spinal cord compression showing partial block *(arrow)* at C-6. *(B)* Same view of myelogram done three years after anterior removal of ridges and fusion, showing normal flow of Pantopaque and absence of ridges.

surgical service at the same time. Observing the postoperative course of these two groups has led us to conclude with Mayfield[3] that the anterior approach offers a less painful postoperative course than the posterior approach. There are two reasons for the lesser amount of pain postoperatively with the anterior approach. Firstly, the anterior approach through the soft fascial plains of the anterior neck causes less pain than the posterior approach through the muscle and fascial attachments to the spinous processes and lamina. Secondly, the offending disk space is immobilized by the tightly fitting bone graft after the anterior but not after the posterior approach. Interestingly, five of the patients in this series were physicians who came to the Mayo Clinic requesting the anterior operation for their cervical radiculopathy because they had arrived at similar conclusions after observing results in their own patients who had had both types of operation.

Although the anterior approach avoids some of the complications of the posterior approach in the sitting position, such as anesthetic and positioning problems, air emboli, and cerebral symptoms from hypotension, it does expose the patient to a different set of potential complications.[6] The most frequent is transient recurrent laryngeal palsy, which occurred in two of our patients. Other rare complications, not seen in this series, are esophageal and vertebral artery injury or Horner's syndrome due to injury of the cervical sympathetics.

The type of fusion done with the anterior operation does introduce the risk of pseudarthrosis and development of a "swan neck" deformity, but this did not develop in any of the 53 spaces fused in this group of patients. In fact, our series includes two patients on whom anterior operations were done because of cervical spine deformities with neural compression that followed posterior laminectomy. Critics of the anterior approach have cautioned correctly that a fusion does increase the strain on the adjacent disk spaces, which are rendered more susceptible to degenerative change. This effect has not occurred in this series, but the longest period of follow-up is only five years. Although anterior-approach operations have been done for over 10 years elsewhere, with some series registering over 500 cases, there are no data to indicate that postoperative deformities are going to be greater after the anterior than the posterior approach.[3,7]

Early in this series we were doing anterior operations only on patients who had foraminal osteophytes with neural compression because the results after posterior operations on foraminal

Fig. 3—*(left)* Lateral view of cervical spine showing severe degenerative changes at C-5 and C-6 interspace. Patient had neurologic evidence of root compressed only at C-6 space. *(middle)* Anteroposterior view of Pantopaque myelogram of cervical spine showing myelographic defect at C-6 space on right side *(arrow)*. *(right)* Lateral view of cervical spine taken after anterior decompression and fusion at C-6 space which was the level of neural compression; bone plug is in place at C-6 space *(arrow)* and interspace height has been restored. The C-5 space was not fused because there was no evidence of neural compression there.

osteophytes were less satisfactory than those for soft disk herniations. When it became obvious that patients with foraminal osteophytes operated on anteriorly had less pain postoperatively than did patients with soft disks operated on posteriorly, and that the anterior exposure was adequate to deal with soft disk herniations, we began operating on the soft ruptured disk, with similar good results. Although patients having the anterior operation for soft disk removal have less neck pain during the first month after surgery than do patients having the posterior approach, there seems to be little difference in the amount of pain thereafter.

If the cervical cord is compressed by spondylitic ridges at only one or two levels, an anterior operation is done; however, most of our operations for spinal cord compression are done posteriorly because the ridges causing cord compression are frequently present at more than two spaces. We are concerned that multi-space fusions will be associated with an unacceptably high incidence of deformity at adjacent spaces, although there is as yet no data to support this concern, and Rosomoff and Rossmann[4] have reported good results in patients who had cervical myelopathy with multiple level fusions.

On the basis of this series of 44 patients operated on at 53 spaces, we conclude that when the preoperative diagnosis is definite, the anterior approach is adequate to deal with the radiculopathy associated with foraminal spurs and ruptured intervertebral disks, and with the myelopathy due to cord compression at one or two levels.

Summary

The results of anterior cervical diskectomy with interbody fusion done by the Cloward technique are reviewed. On the basis of this series of 48 patients we conclude that the anterior approach is adequate to deal with the radiculopathy associated with foraminal osteophytes and ruptured intervertebral disks and with the myelopathy due to cord compression at one or two levels. The results were much better in the group of 36 patients on whom the anterior operation was the first or primary operation than it was in the group of eight patients on whom it was done after a posterior laminectomy had failed to control the symptoms. The neurologic deficit was not increased after surgery in any patient. The most common postoperative complication was a transient recurrent laryngeal palsy in two patients.

Distinguished Physician

Dr. Leslie Zieve, associate chief of staff for research at the Veterans Administration Hospital in Minneapolis, has been appointed a "distinguished physician," one of the highest honors of the Veteran's department of medicine and surgery.

Dr. Zieve has been a professor of medicine at the University of Minnesota since 1962 and is a member of the graduate school faculties in both medicine and biochemistry.

He is the eighth physician in the Veterans Administration to be honored by the appointment. Those appointed to the rank of "distinguished physician" are expected to enhance the various activities "essential to the achievement and maintenance of the highest quality of clinical care in the hospitals of the Veterans Administration."

Dr. Zieve has made major contributions in the field of research, especially in the study of liver function tests and liver disease.

Actinomycosis of the Female Genital Organs

GERHARD O. RICHTER, M.D., JOSEPH H. PRATT, M.D., DONALD R. NICHOLS, M.D. AND CAROLYN B. COULAM, M.D.

A LETTER FROM a woman who had had actinomycosis of her genital organs and who subsequently has been delivered of several children prompted us to review the cases of the Mayo Clinic since the reports of Paalman and associates.[1] In the literature on actinomycosis of the female genital tract, five major review articles exist: by Bucura[2] with 67 cases, to which Hartl[3] added 88 cases; by Cornell[4] with 72 cases, to which Paalman and associates[1] added 45; and by Daniel and Mavrodin[5] with 66 cases. Since 1951 reports of cases have been published by many authors.[6-22] Cross-checking the five major reviews and adding the 17 cases published since, we gathered a total of 196 cases. Not available and, therefore, not included in this summary are reviews in the Russian literature by Karasew[23] with 99 cases, to which Karabanov[24] added another 28, and the cases by Traub and Kovacs,[22] Batizfalvy,[25] Trebicka-Kwiatkowska,[26] Gridaladze and Tataradze,[27] Zawirska,[28] and Podar and Meipalu[29] published in Russian, Polish, and Hungarian journals. Including the two cases (reported herein) that were seen at the Mayo Clinic after Paalman and colleagues[1] had given their report, there are 199 cases published in the western literature until 1964 and more than 300 in the world literature.

This report describes two cases, which illustrate the existing long course of the disease with the possibility of relapses, the excellent outcome after treatment with penicillin, and, in one case, the occurrence of several pregnancies after the actinomycosis was cured.

Report of Cases

Case 1

A 16-year-old white girl was seen for the first time at the Mayo Clinic on Mar. 23, 1947. She had been well prior to an appendectomy performed at another institution in August 1945 (when she was 14 years old) because of generalized abdominal pain; the abdominal pain increased after the operation. Because of the persistence and increased severity of the pain, combined with continuing amenorrhea, dilatation and curettage was done on two occasions several months apart, resulting in temporary relief. One month after the second dilatation and curettage, a "urinary bladder infection" developed and the patient passed a blood clot in the urine. She was then referred to the Mayo Clinic.

She had lost 20 lbs. during the two month prior to referral and was acutely ill during the five days just prior to her examination, with severe abdominal pains, anorexia, chills, and a temperature as high as 102 F. For two days she passed gas but no stool.

On physical examination, she had a pulse rate of 116 beats/min and was acutely ill and anemic. The abdomen was distended, very tense, and tender, especially in the lower quadrants (on the right side more than on the left). There was no visible peristalsis. The uterus was small, fixed by a firm, hard, indurated, 5- by 6-cm mass on the right that extended into the cul-de-sac. Rectal examination revealed exquisite tenderness anteriorly.

The hemoglobin value was 9.4 gm/100 ml; erythrocyte count 3,060,000 cells/cu mm; leukocyte count 19,900 cells/cu mm; and sedimentation rate 80 mm in one hr (Westergren). Urinalysis showed albuminuria of grade 2 and pyuria of grade 3. The chest roentgenographic findings did not show any abnormalities, but a simple roentgenogram of the abdomen revealed many dilated loops but no air-fluid levels. A presumptive diagnosis of tubo-ovarian abscess or pelvic neoplasm was made, and treatment was given with fluids intravenously, a Miller-Abbott tube, sulfadiazine, penicillin, and streptomycin.

In April 1947, an abdominal exploration revealed two pelvic abscess cavities, one behind the bladder and one in the right pelvis. Each abscess contained greenish yellow, nonodorous pus and was drained without excision of any of the pelvic organs.

The bacteriologic cultures grew *Actinomyces bovis*. After surgery, the patient received, by eight intramuscular injections per day, a total of 20,500,000 units of penicillin in 18 days, and 9.5 gm of sulfadiazine orally. The patient was dismissed from the hospital on the 22nd postoperative day. One month later she received another course of 12,000,000 units of penicillin.

The patient was asymptomatic until June 1950, when an examination at another institution revealed a cystic mass in the left adnexal region. The mass was considered

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

a postinflammatory ovarian cyst.

In September 1950, the patient again had severe lower abdominal pain. The pain increased when the bladder was full and was relieved by voiding. No fever, chills, or vaginal discharge was noted. The patient had lost 15 lbs. within three months.

Physical examination revealed the uterus fixed by a large cystic and hard, irregular, nodular mass filling the cul-de-sac and constricting the rectum. The mass extended posteriorly to the right wall of the pelvis. The adnexa were not identifiable. In October 1950, an incision was made and drainage was performed through a posterior colpotomy. An abscessed cavity could not be found in the indurated mass, and cultures did not grow *A. bovis*. This time, 25,500,000 units of penicillin were given during a 24-day period. In November 1950, the patient was dismissed. She received 1,200,000 units of penicillin daily for another month.

Except for fecundity, the patient has had no pelvic problems since 1950. The patient became pregnant and delivered her first child in 1952. Subsequently she has had five other full-term pregnancies.

Case 2

A 30-year-old woman, gravida 3, para 3, with a normal menstrual history, was first seen at the Mayo Clinic on April 23, 1946. She was referred for possible surgical treatment of a "rectal tumor." She had had no bowel or rectal symptoms until two months before her admission to our clinic, when she noted the onset of progressive difficulty in moving her bowels, with the feeling of incomplete evacuation. She denied any history of blood or mucus in the stool. Six weeks before, the patient had been examined by her family physician, who found an indurated rectal mass and referred her to a local surgeon. A colostomy was performed for obstruction of the bowel in the left lower quadrant. At surgery, the mass was seen infiltrating around the rectum and into the broad ligament. A biopsy specimen was not taken. A node was taken and showed inflammatory tissue. After the operation, the patient did well and was referred to our clinic for consideration of further surgical treatment. For three to four days before her arrival, she noted stool in the rectum as well as in the colonic stoma. She had lost 23 lbs. since the onset of her trouble.

On physical examination, her temperature was 99.5 F, but her pulse rate and blood pressure were normal. She was obese but in no acute distress. The positive physical findings were restricted to the abdomen and pelvis. The liver and spleen were not palpable. There was a small, single-barrel colonic stoma, but no masses were felt. The uterus was large, with some thickening in the left adnexal area. The lumen of the rectum was narrowed but regular, with soft-tissue thickening on the left. Proctoscopy and biopsy revealed inflammatory mucosa. The Frei test was negative. The hemoglobin value was 10.6 gm/100 ml, the leukocyte count was 9,600 cells/cu mm, and the sedimentation rate (Westergren) was 99 mm in one hour. A roentgenogram of the chest showed no abnormality.

The patient returned home for six weeks to take warm soda enemas and hot sitz baths three times each day. She was advised to return for closure of her colonic stoma. She returned on June 10, 1946, feeling wel Her stools had been of normal caliber and color an nearly all from the rectum. On physical examination her temperature was 99 F. The size of the coloni stoma was decreasing, and the pelvic and rectal finding were the same as in the previous examinations. Procto scopy revealed a persistent inflammatory process in th rectosigmoid region. Examination of the stool for para sites and ova was negative. In the hope of hurryin resolution of the inflammatory process, the patient re ceived two courses of deep x-ray treatments on two consecutive days; each dose delivered 130 kv to the pelvis She returned home to continue therapy with enemas and was to return in six months for closure of her colonic stoma.

On Dec. 10, 1946, she returned to our clinic. She had had no digestive disturbances for the past six months. The stoma had become smaller, with little stool passing through it. Her temperature was 98.6 F. Pelvic examination revealed a firm mass extending upward from the uterus to the left and fixed between the uterus and sigmoid. Exploratory laparotomy in December 1946, demonstrated a left tubo-ovarian abscess. A left salpingo-oophorectomy was carried out, preserving the right tube and ovary. The colonic stoma was closed at the same time. Pathologic examination of the surgical specimen revealed multiple granulomatous actinomycotic abscesses involving the left tube and ovary. After the operation, the patient did well. She was given penicillin intramuscularly and was dismissed in December 1946.

The patient returned to our clinic on March 3, 1947. She had been doing well until seven to 10 days prior to her arrival, when she noted urgency and frequency of urination. Her family physician gave her medicine to relieve her urinary complaints. However he could not feel a mass in her pelvis. The patient had had normal bowel movements since closure of the colonic stoma. The uterus was partially fixed on the right side with a palpable, fixed, right adnexal mass. The infection from the *Actinomyces* seemed to have extended, and the patient was treated with penicillin and sulfa for four days before subtotal abdominal hysterectomy, right salpingo-oophorectomy, and appendectomy were performed. A right tubo-ovarian abscess had perforated onto the brim of the pelvis and had incorporated the appendix. Cultures from the right ovary subsequently grew *A. bovis*. The patient's postoperative course was uneventful. She received penicillin and sulfa and was discharged on the 16th postoperative day.

The patient was not seen or heard from again until she answered a letter inquiring about her well-being in 1965. In her letter she stated that she has had no further medical or surgical treatment and has been enjoying good health.

Comment

Six patients (four of whom formerly had been reported by Paalman and associates)[1] had long-term follow-up. Of the six patients, one died from active actinomycosis; the cause of death presumably was glomerulonephritis. No permission

or autopsy was granted. All five surviving patients responded to follow-up letters in 1965, and all stated that actinomycosis had not recurred and that their health was good. One patient had recurrence of the pelvic infection after three years in which she was asymptomatic, but ultimately she was cured. This same patient later became the mother of six children. After being treated for pelvic actinomycosis one patient underwent repair of an incisional hernia and a second underwent cholecystectomy; the abdominal cavity of each patient was free of adhesions. Pelvic examination with the aid of anesthesia revealed minimal adhesions in a third patient.

Actinomycosis of the female genital organs is a rare disease. About 60% of all patients with actinomycosis have the infection in the cervicofacial region, 20% in the thorax, and 20% in the abdominal region. Even among the group with abdominal involvement, genital actinomycosis is rare. Putnam and associates[30] found that among 122 patients with abdominal actinomycosis at the Mayo Clinic only 10 had actinomycosis of the genital tract. Since the advent of penicillin, the disease seems to be even rarer because *A. bovis* and *A. israeli* are sensitive to antibiotics. Such treatment, in many cases, prevents actinomycosis after appendectomy or perforation of the large bowel or makes it relatively easy to cure a patient with advanced actinomycosis. Whether there is an actual decrease in the incidence of actinomycosis is not known but, interestingly, only 25 cases of pelvic actinomycosis were found in the literature in the 15-year period from 1950 through 1964 (Table), when treatment of actinomycosis with an antibiotic was routine, whereas in the 15-year period from 1925 through 1939, 87 case reports were found.

An exogenous entry of *Actinomyces* by the chewing of grasses or grains was postulated formerly, but this theory has been disproved because *Actinomyces* organisms are found in the gastrointestinal tract of only a few animals, including man.[1] MacCarthy[17] attributed 91% of 157 cases to an infected appendix.

Putnam and associates[30] noted that 103 of 122 patients with abdominal actinomycosis had had emergency surgical procedures for perforations of the gastrointestinal tract before the development of this disease, but in genital actinomycosis, this relationship is much lower. The symptoms differ from patient to patient.

Our patient (Case 1) was especially interesting since she is the only one in the available literature who not only has become pregnant but has delivered living children. All pregnancies progressed normally and were delivered vaginally.

TABLE

Previously Reported Cases of Actinomycosis of the Female Genital Organs

Year	Number of cases
Before 1890	4
1890-1904	20
1905-1919	26
1920-1934	51
1935-1949	71*
1950-1964	25
Total	197

*Includes 10 cases seen at the Mayo Clinic up to report of Putnam and associates.[30]

Treatment

In many cases, an abdominal exploration is necessary for diagnostic purposes. Surgery consists mainly of incision and drainage of abscess pockets, after which microscopic and bacteriologic examination of pus and tissue is done.[31] If these examinations are suggestive of actinomycosis, removal of the mass and total abdominal hysterectomy or either unilateral or bilateral salpingo-oophorectomy may be performed for the older patient. In younger patients, however, the treatment should be conservative, consisting only of draining the abscesses. The results of treatment with antibiotics are excellent, and there is so little formation of adhesions that pregnancy is possible.

All strains of *A. israeli* or *A. bovis* are sensitive to penicillin and tetracycline in vitro, and most strains are sensitive to streptomycin. All strains of the fungus that we have cultured have been inhibited by 0.1 μg or less of penicillin G per cubic milliliter of culture medium. Our experience[32] in treating more than 150 patients who have had actinomycosis involving various portions of the body has established that both penicillin and tetracycline are effective agents. If the disease has been present sufficiently long to permit an overgrowth of fibrous tissue, formation of sinuses, or an impairment of the general health, effective management of the infection has been much more difficult and chemotherapy over many months has been necessary.

In actinomycosis, if penicillin is selected for the treatment, at least 1,000,000 units of procaine penicillin G should be given intramuscularly daily for a minimum of six weeks. Penicillin G or V

orally can be tried when the infection is mild, but the intramuscular route of administration is preferable for the more extensive forms of the disease.

Various studies and our own experience have indicated that the tetracyclines also are effective agents in the treatment of actinomycosis. The usual program that we have followed in recent years has been the use of tetracycline, 500 mg every six hours orally, for at least four weeks. We have found it necessary at times to administer the tetracycline for six months or more before we have had evidence that the fungus has been eradicated. Although penicillin has been regarded as the drug of choice in the treatment of actinomycosis, tetracycline in some instances may be preferable, particularly in patients who are allergic to penicillin.

In certain patients in whom response to a single antibiotic has been disappointing, we have used streptomycin in addition to penicillin or tetracycline. Results with this combined therapy have been sufficiently encouraging to warrant further investigation of such a program. If streptomycin is used, the daily intramuscular dose should not exceed 1 gm, and the drug should not be used longer than four weeks at this dosage.

The results of treatment with antibiotics are excellent. Whereas actinomycosis was formerly almost always fatal, the susceptibility of *A. bovis* or *A. israeli* to antibiotics has changed this during the past 25 years. Every case report formerly stressed the long protracted course and the small chances of cure; however, all reports since 1950 agree on the good results with antibiotic treatment. Of 17 patients whose case reports were available to us, only one patient with genital actinomycosis died; both diagnosis and treatment were delayed. Of the six patients seen at the Mayo Clinic since 1945, only one died, while suffering from an active actinomycosis, presumably from glomerulonephritis. The other five patients were alive and well, 12 to 19 years later.

Summary

Two cases of actinomycosis involving the female genital organs are added to the existing 197 reports in the literature. Both patients were cured by combining surgery with antibiotic therapy. The number of reported cases of actinomycosis involving the female genital organs has decreased greatly during the past 20 or 25 years, probably because of treatment with antibiotics. The clinical course has been shortened markedly, and the chance of survival of the victim with this once fatal disease is nearly 100%. Surgical treatment in young girls should be conservative. One of our patients treated by drainage of abscesses and with penicillin was subsequently able to bear six children.

Break the ulcer circuit to hyperacidity, hypermotility and ulcer pain.

Pro-Banthine®
propantheline bromide
A Relief Factor in Peptic Ulcer

Worry, frustration, job pressure—all set up excessive vagal currents in patients with peptic ulcer.

Pro-Banthine "insulates" the stomach, the duodenum and the lower intestinal tract—the sites where these destructive currents take their toll.

This "insulation" helps block excessive enteric activity and acidity, thus helping to provide the proper environment for the healing of peptic ulcers.

It's nice to know that Pro-Banthine provides this protection at a dosage that causes little or no discomfort and that, unlike ataractic agents, Pro-Banthine does not cloud the patient's awareness or thought processes.

By moderating excessive vagal currents Pro-Banthine relieves spasm, acid burn and pain. By reducing gastric motility Pro-Banthine also prolongs the activity of antacids.

Indications: Pro-Banthine is effective as adjunctive therapy in the treatment of peptic ulcer. Dosage must be adjusted to the individual.

Contraindications: Glaucoma, obstructive disease of the gastrointestinal tract, obstructive uropathy, intestinal atony, toxic megacolon, hiatal hernia associated with reflex esophagitis or unstable cardiovascular adjustment in acute hemorrhage.

Warnings: Patients with severe cardiac disease should be given this medication with caution. Fever and possibly heat stroke may occur due to anhidrosis.

In theory a curare-like action may occur, with possible loss of voluntary muscle control. For such patients prompt and continuing artificial respiration should be applied until the drug effect has been exhausted.

Diarrhea in an ileostomy patient may indicate obstruction, and this possibility should be considered before administering Pro-Banthine.

Precautions: Since varying degrees of urinary hesitancy may be evidenced by elderly males with prostatic hypertrophy, such patients should be advised to micturate at the time of taking the medication.

Overdosage should be avoided in patients severely ill with ulcerative colitis.

Adverse Reactions: Varying degrees of drying of salivary secretions may occur as well as mydriasis and blurred vision. In addition the following adverse reactions have been reported: nervousness, drowsiness, dizziness, insomnia, headache, loss of the sense of taste, nausea, vomiting, constipation, impotence and allergic dermatitis.

Dosage and Administration: The recommended daily dosage for adult oral therapy is one 15-mg. tablet with meals and two at bedtime. Subsequent adjustment to the patient's requirements and tolerance must be made.

How Supplied: Pro-Banthine is supplied as tablets of 15 and 7.5 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg.

Ampicillin, Carbenicillin, Oxacillin...

IMAGINE YOUR PRACTICE WITHOUT THEM

In 1957 Beecham scientists discovered and isolated 6-APA, the penicillin nucleus that opened the way to a new generation of semi-synthetic penicillins. Over the past 14 years more than 3000 different semi-synthetic penicillins have been synthesized and evaluated by our staff. The fruits of their work are in your hands today. Others will be in your hands tomorrow.

Editorials

The Accident Prone Physician Pilot

Is flying a suitable avocation for physicians? The question arises after reading an account of 15 fatal accidents involving physician pilots.* All of these accidents were chargeable to pilot error. None was caused by engine failure. Three airplanes had "structural" failure (read: the airplane fell apart in the air) in every case due to pilot error imposing excessive stress on the airframe. Nine involved flight into weather conditions beyond the ability of the pilot to handle. Eight involved night flying. One of these pilots took off for a flight northwest; was observed by the tower operator to be flying southeast and changed course only after his reciprocal bearing was pointed out. A pilot took off with his controls locked. One inadvertently landed downwind. Two were drunk. (Numbers are greater than 15, because in several there were multiple factors involved). It is evident from these reports that some of these pilots scarcely knew which end of an airplane was up when they took off with their passengers on their last flight. The article does not state the base, the total number of physicians currently flying, but a ballpark figure for the United States is 3600 based upon the 2400 membership of the Flying Physicians' Association and the estimate that two out of three physician-pilots belong.

So the annual fatality rate for 1971 is 420/100,000, right up there with heart disease, cancer and stroke. Actually a total of 42 people were killed in these 15 accidents, but there is no base figure for passengers.

One pilot attempted a night landing at his home base of Atlantic City but unfortunately confused east for west and with a west wind gusting up to 23 knots landed toward and eventually into the Atlantic ocean. Four drowned. Can anyone conceive the egregious error of a takeoff with the controls locked? A physician managed to do that. One of these fatal 15 in 200 hours of flying never bothered to increase his student rating.

If one common failure can be pinpointed among these sorry stories it is the lack of respect shown by these flyers for their machine and the art, coupled probably with unwarranted over evaluation of their own flying skill. It may be that long indulgence in careless practice of medicine with errors suppressed and mitigated by a forgiving nature leads to a similar approach to flying where errors are more sternly punished.† Safe flying is a personal matter, an over-riding desire to do it right. Flying instructors, Federal Aviation Authority examiners can assist but fundamentally safety is self-engineered.

Surely physicians can fly, thousands fly well and safely. But there are hazards, 99% of which are generated within the man (in this particular group, 100%). Physicians who fly or plan to take flying training are urged to read the article in the July 1972 issue of The Flying Physician. It will be a heuristic experience.

*Woods, P: Fatal M.D. Pilot-in-command flight accidents. The Flying Physician 15:28. 1972.

†The flight instructor has difficulty establishing a teacher-student relationship with such a doctor. He may never be able to instill proper aviation discipline.

DOCTORS.

Is your investment portfolio suffering from one of these diseases?

1. Piecemealitis.

A common disorder characterized by fragmented investing — buying a little bit here, a little bit there; usually the result of simple disorientation on the part of the investor.

2. Hot-tip-a-mania.

A compulsive, devil-may-care disease; usually manifests itself following phone calls from friends about "hot" investment tips; generally communicated orally.

3. Apartmenthousitoma.

An affliction which commonly strikes those in the medical profession who are attracted to get-rich-quick real estate ventures; can cause great financial pain and mental anguish, especially in a market that's overbuilt.

4. Multiple brokerosis.

A state of investment confusion which results from dealing with too many different counselors; characterized by the left hand not knowing what the right hand is doing.

5. Simple neglect.

A minor failing which, if not dealt with, can develop into a critical disorder; caused by not having enough time to care for investments properly; common not only to physicians, but to dentists, lawyers and most highly-paid business executives, as well.

What's the cure?

If you have an investment portfolio with $50,000 or more in securities, and you have the slightest fear that it's suffering from any of the above diseases, we strongly urge you to consult a Professional Investment Adviser at Northwestern/St. Paul.

We know all about diseases like that. And how to cure them.

In fact, we specialize in working for busy professional men who want to get and keep their investment portfolio on the road to good health.

We'll do the same for you, for as little as $300 per year (or less than 1% of the amount of your total investments).

Our credentials.

The people on our staff are all highly-trained, experienced specialists. In stocks. Bonds. Income. Gains. Taxes. The entire investment field.

When they go to work on an investment problem, they don't make top-of-the-head diagnoses.

They deal with facts. Proven facts. Facts gained from research (something we believe in).

So, they won't promise you any get-rich-quick "miracles". But they will offer you the prospect of good, steady, dependable, healthy growth.

Last year, in fact, a national professional journal* ranked our bank's investment performance among the top ten banks in the entire nation.

Want to learn more?

Why not bring in your investment portfolio for a financial checkup?

One of our specialists will give it a thorough examination (in light of your investment goals) and prescribe whatever he feels is necessary to put it in tip-top condition.

It won't cost you an arm and a leg. But it could save you thousands of dollars. And provide your investments with a long and prosperous life for the years ahead.

Just fill out the blank below and drop it in the mail.

Your portfolio has nothing to lose. Except what ails it.

*Details on request

I'd like an appointment.

Please telephone me to set up an appointment for my investment portfolio exam and diagnosis.

Hysterical Neurosis

Doctor Flemenbaum* sharpens the clinical description of the hysterical neuroses. He directs attention to certain of these patients whose elaborate neurotic defenses make accurate diagnosis difficult. Actually, because of the more refined diagnostic methods for physical disease and because of increased psychiatric knowledge among all physicians, the number of patients suspected of having conversion disorders is increasing. It is no longer sufficient to recognize only the patient who is obviously mimicking organic disease; the seductive, dramatic, paralyzed young woman, indifferent to her plight, is more a caricature out of psychiatric annals than a real representative of the somatisizing neuroses.

Flemenbaum emphasizes that an increasing proportion of hysterical patients give a premorbid history not of obvious superficiality, helplessness, and inadequacy but rather of competency and self-sufficiency (albeit superficial or inconsistent on more careful examination). Rather than the patient being suddenly incapacitated, the course is one of having gradually to "give in" to long-complained-of illness and give up "cherished" responsibilities. Highly symbolic stresses less commonly contribute to the conversion than a family or physician that reinforces the "illness."

As diagnostic sophistication increases, and as we begin looking at the male more objectively, I suspect that the apparently high ratio of women to men with conversion hysteria will diminish. This is already obvious in the area of the compensation neuroses.

Left Ureteral Obstruction

The recent report by Gilman, et al.* of left ureteral obstruction following ileac diversion of urine adds another cause to the growing list of late complications to this procedure. Gilman documents five cases out of eighty seven ileac diversions in which three cases revealed obstruction of the left ureter as it hooked under the inferior mesenteric artery. As Gilman stated, bringing the ureter through the mesocolon anteriorly would probably eliminate the problem. Other major complications such as obstruction at the skin and anastomatic levels, stasis, reflux, infection and stone formation have been reported as high as twenty five percent in some series of cases following ileac diversion. The benefits of the operation are great in patients who must have this form of diversion but the risks are significant. Candidates must be carefully evaluated. Ileac diversion should be reserved for malignant disease, neurogenic disease of permanent nature and only certain other irreversible conditions.

Gordon W. Strom, M.D.
Minneapolis, Minnesota

*Gilman LS et al.: Left ureteral obstruction. Minnesota Med 55:9:784, 1972.

Pancreatic Scanning

Doctor McGill, Wahner and Tauxe* present an interesting comparison of observer variation in accuracy of pancreatic scan interpretations alone. One important cause of these variations appears to be differences in confidence or at least in willingness to avoid the "indeterminate" category. If we all could more easily identify and learn to accept an "indeterminate" scan as just that, we could at least hope to reduce the number of false positives and perhaps obtain better service from this technique in an area in which other non-surgical methods have had great limitations.

Stanley C. Von Drashek, M.D.
Minneapolis, Minnesota

*McGill DB et al: Pancreatic scanning. Minnesota Med 55:9:796, 1972.

Cervical Disk Disease with Neural Compression

THE ARTICLE by Doctors Rhoton and Henderson* from the Mayo Clinic appearing in this issue of MINNESOTA MEDICINE is both informative and timely.

It has long been recognized by neurosurgeons that the classical posterior cervical approach for bony osteophytic spurs or so-called "hard discs" often times leads to less than optimum postoperative results. Because of the anatomy involved, it is frequently very difficult or impossible to satisfactorily remove the hard, bony osteophytic spur lying immediately anterior to the nerve root. In such situations, it is not unusual to have patients return with persistent complaints of pain, sensory disturbances and continuing motor dysfunction.

The anterior approach, as outlined in this article, makes it possible to remove the offending osteophytic spur or spondylotic ridge quite completely. It has been our practice to carry the dissection to the posterior longitudinal ligament, then incise the ligament and using a small, 45-degree angled Kerrison rongeur, remove the ligament and the spondylotic ridge or spur by working in the plane between the ligament and the anterior aspect of the dura mater. We feel that a thorough removal of the osteophytic spur can thus be effected.

Our experience with this type of operation reveals that the best results occur when only one interspace is involved. We have done a good number of two level fusions, but the long term followup has not been as rewarding as with the single lev We have seen a number of patients who have h three to five level fusions done elsewhere wl persist with a multitude of complaints referable the head, neck and arms.

Consequently, if the disease process of the ce vical spine is not limited to one or two levels, v feel that the posterior approach with a wide d compressive laminectomy, foraminotomy and de tate ligament section, should be carried out.

Our experience with one or two level fusio for osteophytic spurring and spondylotic ridges excellent and corroborates the authors' result We have little experience with the anterior a proach for acutely ruptured intervertebral disc It has been our practice to deal with these fro the posterior approach. With the excellent resul reported in this article, perhaps more ruptur cervical discs should be dealt with anteriorly.

This procedure is not only useful in handlir spondylotic ridging, osteophytic spurring and ru tured cervical discs, but also in select cases, has been helpful in dealing with fractures of th cervical spine.

The anterior surgical approach to certain di ease processes of the cervical spine has withstoo the test of time and has proved to be a highly su cessful procedure in the neurosurgeon's operativ armamentarium.

Longstanding Colon Polyp Malignancy

CARCINOMA OF THE colon continues to be an important medical entity. It is currently estimated that approximately 12% of all cancers arise from the colon or rectum. An estimated 47,000 deaths directly attributable to colon cancer are expected in 1972. What is further discouraging is that the death rate from colon cancer has not changed significantly in the past 30 years. Routine medical evaluation, proctoscopic examinations, stool analysis and periodic roentgenographic bowel evaluations have not enhanced significantly the early detection of colon cancer. Surgical procedures and medical treatment have not altered survival significantly.

In a case report in this issue, Mongé* discusses the relevance of a colonic polyp as it relates in time to the development of a carcinoma.

Medical literature is controversial regarding the premalignancy of colon polyps; yet there does seem to be some poorly defined relationship between certain adenomatous polyps and carcinomatous changes.[2-5] Clearly, what is needed is a tumor specific test that would detect early colonic cancer.

See page 986.

Gold[6] in 1965 reported the discovery of an antigen found in high proportions (97%) in patients with colon cancer. As yet this test is not readily available to most physicians. Further investigation of this carcinoembryonic antigen (CEA) has shown this not to be specific for colon cancer.[7] The CEA assay currently appears to be useful in the followup of patients with colonic cancer, and in the future, may be more of a diagnostic aid.

Barium examination of the colon may reveal early mucosal changes as well as polyps, but the histologic diagnosis remains essential. The clinical decision to obtain tissue by laparotomy is many times difficult. Recent wide spread use of the fiberoptic colonoscope has enabled physicians to view the entire colon, biopsy suspicious lesions, and snare pedunculated polyps.[8-9] This instrument makes histologic diagnosis much easier and serves as a way of following mucosal alterations.

Utilization of all the available techniques will bring about a better understanding of which polyps are most likely to undergo malignant changes, and in effect help make the diagnosis of colonic cancer earlier.

Neil Hoffman, M.D.

Technique for Placing Umbilical Catheters

This article by Dr. Strickland* poses one of the philosophic questions for which there is no glib answer. The use of a catheter in the umbilical vein has made exchange transfusion possible and relatively safe in almost any general hospital with a good laboratory and a obstetrical department. The use of arterial and venous catheters to monitor blood gases in critically ill infants poses the relation of risk to salvage. It is not possible to monitor all ill newborns in every community hospital, nor can every pediatrician become as adequate a neonatologist as Dr. Strickland. It seems we should lean more and more to centers where the high risk infant can be cared for. Often times, the risk of travel to a center is less than the risk of hazardous procedures in unskilled hands.

Cover Photograph

"November Song"

The photograph on the cover of this month's issue was taken by Dr. John Wendland five years ago during a trip he and his family made to enjoy the fall foliage. He recalls the area as being around Red Wing and at the time was impressed with this particular field of wheat as this method of harvesting wheat is disappearing from the farm scene. Most of this is done by combine.

Dr. Wendland is an ophthalmologist practicing in Minneapolis, a clinical professor of Ophthalmology at the University of Minnesota and a consultant in ophthalmology at the Veterans Hospital. He skis, climbs mountains and excels in making motion pictures for his personal use.

Letter to the Editor

To the Editor:

The latter-day barber surgeon, dignified as the "assistant physician,* "the medico." "serving a doctorless town," may be defined as an ex-corpsman or a former hospital orderly or other attendant who has taken a two-year course in the intricacies of assisting a physician. (To become a licensed physician without specialty requires nine years.)

After nine months of didactic training in courses of anatomy, physiology, physical diagnosis, and electrocardiography, the "assistant physician" may spend 15 months more in clinical experience, rotating through a four to eight weeks' course in the practical aspects of the various specialties of medicine and surgery. (To become a specialist in medicine or surgery requires three to six more years.)

In this "clinical arena" he learns "how to attend the patient's needs, order appropriate laboratory tests, make rounds, and assume other responsibility."

This novitiate in medicine is proudly endorsed by health care organizations and by politicians as a panacea for the delivery of health care; for what more ideal method of wooing the voter into Federally-controlled medicine is there, than supporting a solution for an erroneously developed public-image: the medical-care impasse!

The medico has found that his greatest contribution was by having "him work at the hospital while his physician spends most of his time in the office."

The assistant physician feels that he is competent to do a complete history and to make a complete physical examination, "including pelvic examinations on women;" he also maintains that he can arrive at a tentative diagnosis and order the appropriate laboratory tests. And, believe it or not, he feels that his service is not even used to its full potential, because he believes that he can be given the responsibility of such sophisticated tasks as "lumbar puncture, peritoneal dialysis, cut-downs, funduscopic examination, and determine the severity of the hypertension just as easily as can the physician." Furthermore, the physician's assistant maintains that he can "feel the diastolic apical thrill, hear the opening snap after the aortic second sound and the diastolic apical rumble of the mitral stenosis, and make a diagnosis of mitral stenosis—when it has been previously overlooked by others;" and still more the responsibility of performing a highly technical task such as assisting with or actually "performing right heart catheterization—ordering the electrocardiogram —in addition making an accurate interpretation of it."

In doing research work on the dog he maintains that he can perform the anesthesia, and also "complete the entire experiment." So why *we* should bother to study diligently for 12 years and then have the physician's aide assume all the responsibility, while we sit in the office waiting for him to arrive and "do the histories, conduct the pre-employment examinations, sew up the minor lacerations, change the casts," etc., is a mystery. With all that, what is there left for the physician to do?

It is certain that we can utilize assistance in our practice, but the crying need for more "health care delivery" should not be allowed to abrogate high standards and sanction inferior medical service. It seems superfluous that we must now become so involved in establishing a whole new specialty which would involve legalities, new schools, curricula, teaching staff and the thousand-and-one other imponderables, when we have so close at hand nursing schools (male and female eligible) which are immediately available and could readily adjust to the training of young men and women to become "doctors' assistants" just as nurses have

*Lewis Cope, Minneapolis Tribune, Dec. 9, 1971.

always been or as we have trained them for our own use.* It is a disservice to the very honorable and efficient nursing schools and their profession to circumvent them. Their training program is infinitely better than the two-year program that is being designed for "assistant physicians."

Thirty years ago my associate and I trained, on the job, several graduate nurses to attend to the ancillary duties of taking preliminary histories and making preliminary rounds; starting intravenous fluids, drawing blood, collecting data, changing dressings, removing casts and taking out stitches; observing temperatures, pulse and blood pressure, and in general having vital signs and physical facts at their fingertips in order to assist us in discharging our own responsibility more efficiently. We also trained a few nurses to assist at surgery in the manner in which we wanted them to be our assistants. On no occasion would we have allowed anyone but a physician to assume the responsibility of "ordering medications, doing definitive physical and pelvic examinations, interpreting eye ground and cardiac murmurs; carrying out heart catheterizations, spinal punctures, peritoneal dialyses; suturing lacerations, putting on casts," and a host of other critical procedures that require the judgment of a fully-trained physician. These vital responsibilities have always been the trust of the physician and should continue to remain so.

Now, after a professional lifetime in the field of General Surgery, it seems that my generous heritage of good health has carried me full circle, for I clearly recall, before the First World War, as a young, eager, high school student, that my ambition was to go to the University of Valparaiso,† Indiana, where I could complete the entire medical training in two and one-half years. In my youthful enthusiasm, idealism and naivete, I visualized how wonderful it would be, at the end of that time, to start serving humanity.

But shortly after I had finished high school, and a couple of years in the A.E.F., World War I convinced me of the need for more education, not less; thereafter, at the end of 12 more years, I completed my medical and surgical training. Now, we are about to be relegated to the bleachers of the "clinical arena" to watch the latter-day barber surgeon take the spotlight in medicine that we had, half a century ago, so eagerly dreamed of achieving and maintaining. It seems that in our eagerness to satisfy the clamor of the numerous malcontents we are spawning a new profession that may prove to be more troublesome than some of the cults.

Carl O. Rice, M.D., Ph.D.
Editor Emeritus

*Heartily support Dr. Madeline Leiniger, Minneapolis Star, 8/10/72.
†Long since discontinued.

Dear Editor:

I am delighted that you published the wonderful manuscript entitled "The Development of Thoracic Surgery in the Upper Midwest" by Tom Kinsella as a supplement to the August, 1972 issue of MINNESOTA MEDICINE.

Tom was my student in Anatomy for a school year in 1915. At that time, I developed a high regard for him which has continued to the present moment.

When I published a multiple authored book in 1959, Tom's chapter on *Tumors of the Chest* was and is a classic. It was so excellent that I contacted the publisher Charles C. Thomas and recommended that it be reprinted in book form. Tom took great pride in that book.

In 1965 I suggested that he write the history of other phases of his chest surgery as he had done for tumors. He worked on this project until his death. I talked with him once after he entered St. Mary's hospital in November, 1969. He had taken a part of the manuscript to the hospital where he was putting in some finishing touches. However, when he died on November 12, 1969 some necessary work on the references remained. His long time excellent secretary Mrs. Florence Olson completed the manuscript.

The original of Kinsella's manuscript is on file in the University of Minnesota Library.

J. A. Myers, M.D.
Minneapolis, Minn.

The Viewing Box

Middle-Aged Woman with Dysphagia

EDWARD A. PETERSON, M.D.

THE PATIENT was a 47-year-old woman who entered the hospital complaining of dysphagia, weight loss, easy fatigability and vasospastic phenomena of the hands. She also had mild exertional dyspnea with slightly productive cough. X-ray examination of multiple systems disclosed many positive findings (Figures 1-5).

Diagnosis: Systemic scleroderma

Systemic scleroderma is of particular interest to the radiologist because of its many roentgenographic manifestations. The chief findings are as follows:

(1) The lungs show intermittent episodes of pneumonitis and pleuritis progressing to pulmonary fibrosis in the middle and lower thirds (Figure 1). This is interstitial in type.

(2) The heart shows non-specific enlargement of the cardiac shadow (Figure 1) with occasional pericardial effusion.

(3) Gastrointestinal tract has several manifestations. The esophagus is the most often affected. There is diffuse dilatation of the esophagus (Figure 2) with diminished or absent peristalsis. This is best seen in the recumbent position.

Fig. 1—Mild cardiac enlargement and fibrosis in basilar portions of both lungs.

Fig. 2—Esophagogram showing dilatation and diminished peristalsis of the esophagus.

Fig. 3—Small bowel study discloses dilatation of duodenum and jejunum.

Fig. 4—The barium enema reveals loss of haustration of the colon with some tendency to saccule formation.

Fig. 5—Wrist and hand: Decalcification of bones, soft tissue calcifications in the wrist and some absorption of distal ends of the terminal phalanges with adjacent calcification.

(4) Small bowel involvement is relatively common. Irregular areas of constriction and dilatation (Figure 3) are usually present with absence of mucosal pattern and delay in transit time.

(5) The colon has a bag-like appearance (Figure 4) with widemouthed saccules.

(6) The musculoskeletal system has rather characteristic features. There is tapering or absorption of the tips of the terminal phalanges (Figures 5) with multiple soft tissue calcifications (Figure 5) present in addition to periarticular soft tissue changes. Occasionally, large masses of calcification are seen about the joints, producing a so-called "tumoral calcinosis."

Request for Physican's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers has received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Because of limitation of space, pictures oriented horizontally are preferred. All pictures will be returned if identified with the name and address of the physician. Please submit your pictures as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

Farrell Stiegler, M.D.
Cover Editor

New Director

Dr. George Mann has been named director of the Alcoholic Treatment Unit of St. Mary's Hospital, Minneapolis, and medical director of the Johnson Institute, an outpatient chemical rehabilitation center in Minneapolis.

Dr. Mann had been medical director of the St. Mary's unit since it opened with 16 beds in December, 1968. Now, as director of the 52-bed unit he is responsible for all phases of the two year, inpatient-outpatient, medically-oriented therapy and counseling program.

After receiving his M.D. in 1949 from Marquette University, Dr. Mann went into general practice until 1952 when he began a residency in anesthesiology at the University of Minnesota. He is certified by the American Board of Anesthesiology.

Procedures in Brief

Technique for Placing Umbilical Catheters

MARTHA BURKE-STRICKLAND, M.D.

THIS IS A PRESENTATION of technique only. Philosophy, uses and complications may be found in the listed references.

Precautions During the Procedure

During the procedure, monitor the infant's color, heart rate and respirations. Keep the baby warm. Maintain a rectal temperature of 37°C (98°F). Carry out the procedure within the incubator if a separate draft-free, thermistor-controlled heated work area is not available.

Work rapidly; prolonged procedures are extra stress for the baby. Properly organized, the complete procedure should not take more than ten minutes.

If the baby is in shock, cannulate the vein and initiate therapy before manipulating the arteries.

Maintain sterile technique.

Catheter Recommendations

A No. 5F blunted, open-end, radiopaque, polyvinal catheter* is suitable for most purposes. A No. 3F is available for use in infants weighing less than 1,000 grams. A No. 8F is available for exchange transfusions.†

Gavage feeding catheters are a poor substitute for umbilical catheters. The blind-end side hole predisposes to clotting; the side-hole is frequently occluded by arteriospasm; "adapting" the tube by cutting off the blind end leaves a sharp cutting edge that damages the vessel and increases risk of perforation.

Other Equipment

Set-up for the procedure should include adequate lighting, a Mayo stand, restraints for the baby, a constant infusion pump‡ if intravenous fluids are to be given, and a sterile umbilical tray.

The tray should contain:

—4 towels
—cotton balls
—gauze sponges
—2 curved mosquito hemostats
—1 thumb forcep
—7" straight jaw needle holder
—7" ring forceps
—2 5cc syringes
—1 oz. medicine cup filled with parenteral saline
—1 oz. medicine cup filled with Betadine
—curved cutting skin needle with 4-0 silk or woven nylon suture
—Bard-Parker handle with No. 11 blade
—5" straight scissors, blunt-sharp blades
—fine plain tip iris forceps —1 curve, 1 straight
—1 woven umbilical tape
—2 umbilical catheters
—2 disposable 3-way stopcocks

The capped end of the IV line should be readily accessible for attachment to the catheter when the latter is in place.

Safe restraints can be made by looping one end of a length of curlex gauze around the wrist or ankle. Tape in place to form a soft, snug bracelet, Position the extremity comfortably out of a field of action and secure by taping the free end of curlex to the incubator mattress frame.

Preliminary Procedure

The steps described are for working inside an incubator. Starred steps may be omitted if open facilities are used.

*Remove the iris covers from the portholes to facilitate sterile entry of the gloved hands.

The physician should scrub, put on sterile gloves and finish preparations for the procedure:

Assemble the Bard-Parker handle and blade, assemble needle and suture in needle holder, fill catheter with saline; leave catheter attached to syringe.

Place cotton balls in Betadine.

*Open one towel completely. Lay all instruments and supplies in the center. Fold the towel, envelope fashion, over the contents to make a spill-proof pack.

*While an assistant opens the access door to the incubator, place the pack over the lower ex-

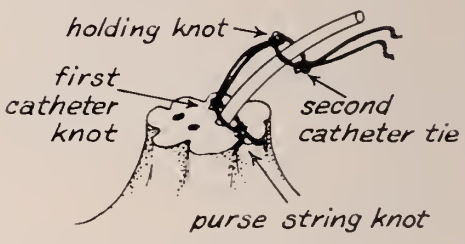

Figure 6. Completed Tie

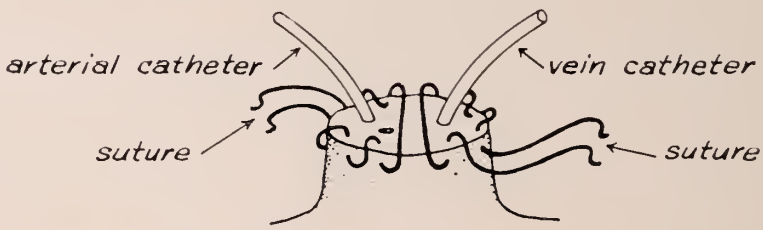

Figure 7. Separate Purse Strings for Arterial and Venous Catheters

tremities of the infant. The incubator is closed and the rest of the procedure is performed through the portholes. At this point, everything needed to complete the procedure should be inside the incubator. Avoid going in and out the portholes repeatedly.

Preparing the Site

Unfold the pack. While an assistant holds the cord stump off the abdomen, cleanse the stump and adjacent skin with Betadine. Avoid abrading the thin skin with rough scrubbing. Discard the used cotton balls and ring forceps away from the sterile area. Position the three towels to form a sterile field around the cord. Place the woven tape around the cord base in a single over hand tie to provide vessel control during the next step.

Use the Bard-Parker knife to sever the cord with a clean, even cut about ½ cm from the skin. Discard the remnant away from the sterile area.

Vessel Identification

Identify the arteries and vein with minimal manipulation of friable tissues. Remember that the vessels follow a spiral course through the cord. If the cord has been cut near the skin, the thin-walled, patulous oval lumen of the vein should be near the 12 o'clock position. The small, pinpoint lumina of the arteries should be seen jutting slightly above the surface of Wharton's jelly at 4 and 8 o'clock positions. If the infant is moribund, relaxed arterial lumina may be difficult to distinguish from the vein.

Catheter Insertion in the Vein

To cannulate the vein, remove any visible clot with a forceps, grasp the tissue near the vein with a curved mosquito hemostat, loosen the woven tape, quickly insert the catheter and advance to a premeasured length equal to the distance from the umbilicus to the xiphoid process. Retighten the woven tape. Keeping the vein occluded and using a saline filled catheter are essential for prevention of air embolism.

Obstructive kinks in the vein 1-2 cm beyond the abdominal wall may be overcome by exerting a steady, gentle pressure with the saline filled syringe as the catheter is advanced.

Rarely a problem at birth, obstructive clots encountered later may sometimes be removed by exerting a negative pressure with the syringe as the catheter is withdrawn. Clear the clot and reinsert the catheter. The risk of embolization or perforating the vessel is increased by forcing the catheter or pushing with a metal probe.

Position of Catheter in Vein

The catheter tip should lie in the inferior vena cava just about the diaphragm. If it cannot be advanced to this point, it may be left in the umbilical vein. The tip should not lie in the heart, the portal vein or branches of the hepatic vein. Check position with Xray before injecting hypertonic solutions.

In an emergency, insert the catheter only 1-2 cm for injection of medications. When the emergency is over, a new catheter can be placed in the desired position.

Cannulating the Artery

Catheterizing the spastic pinpoint lumen of an artery requires more skill. Stabilize the end of the artery by grasping adjacent tissue with a mosquito forceps. Insert the tip of the curved iris forceps into the lumen; allow the jaws of the forceps to open, exerting a gentle dilating pressure on the vessel. Insert the catheter tip between the jaws of the forceps. Continue to exert a steady, gentle pressure for 15-30 seconds. When the muscular spasm relaxes, the catheter begins to advance more freely. On rare occasion, injection of 0.1 cc of 1% Lidocaine may be needed to relieve the muscular spasm.

If the catheter will not negotiate the curve at the junction of the umbilical artery with the hypogastric artery after 30-60 seconds of gentle pressure or injection of the Lidocaine, try the other artery.

Advance the catheter a length equal to the distance from the umbilicus to the symphysis plus 3 cm. This will usually put the tip in the iliac artery. The catheter should not lie in the femoral artery nor adjacent to major visceral branches of the aorta. The catheter should be removed at once if there is unremitting vasospasm or other sign of disturbed circulation.

Securing the Catheters

If both arterial and venous catheters have been inserted, secure them with separate purse string sutures placed in the wall of the cord, not the skin. Snug the tissue up around the catheter and tie; wrap the suture around the catheter one time and tie again. Make a holding knot one cm beyond this, wrap the suture around the catheter

and tie again.

If only the vein has been cannulated, a single purse string suture should include the ends of the arteries to insure hemostasis.

An anchor suture in the wall of the cord with a tie around the catheter is not satisfactory for hemostasis nor prevention of air embolism around the catheter.

The woven tape should be removed from the base of the cord as soon as suturing is completed.

Tape the catheter to the abdominal wall with a ⅜″ x ¾″ strip of tape. Position so no torque pressure is exerted on the wall of the vessel. Tineture of benzoin to the skin before applying the tape improves holding and reduces skin irritation.

Dressings

No gauze dressings are used. Apply Neosporin and Myeostatin powder every four hours. Prevent inhalation of the powder by the baby. Creams and ointments are not recommended for use on the cord.

Cystic Fibrosis

Screen Newborn Infants

WARREN J. WARWICK, M.D.

LIFE TABLE STUDIES of the survival of different groups of patients with cystic fibrosis have shown a very poor prognosis without special treatment, a three-fold improved prognosis with special treatments, and an estimated ten-fold improvement with prophylactic pulmonary therapy.

Before 1939, when no effective treatments were known for cystic fibrosis, the survival curve for children with the disease was grave—only half of the children (97 diagnosed before 1939 and reported in the medical literature) were alive at eight months of age; only one-fourth were alive at one year, and only one was alive at age 10 years.[1]

After 1939 when antimicrobial drugs became available the survival curves showed half of the children still alive at 3½ years; one-fourth alive at nine years and about eight percent at 20 years.[2]

After the National Cystic Fibrosis Research Foundation started funding special Cystic Fibrosis Centers across the United States, prognosis improved even more. Throughout the United States the averaged survival for these children with cystic fibrosis reported from 78 Cystic Fibrosis Centers showed one-half still alive at 11 years and one-fourth alive at 20 years.[3]

These data also show that the interval from the age of diagnosis for children diagnosed between birth and 10 years of age to the death of one-half of the group was on the average 11½ years. This mortality pattern, that of an acquired disease, suggests that children with cystic fibrosis grow without special risks until some clinical pulmonary complication triggers a progressive destructive course.[3] These data support the thesis which prompted clinical study of a "prophylactic" approach to pulmonary therapy at the Western Reserve University.[4]

If prophylactic pulmonary therapy does prevent such a triggering event in the lungs, the remarkable survival curve achieved by Matthews, Doershuk and colleagues[4] is easy to understand. Their results, two-thirds of patients predicted to be alive at 19 years,[3] provide the best current argument for finding the child with undiagnosed cystic fibrosis before he develops symptoms.

How well are we doing? If the incidence of cystic fibrosis is near one case in every 1000 newborn infants, our data in Minnesota indicate that fewer than 20 percent of the cases are diagnosed. Because of this difference between predicted numbers and known prevalence, we planned a survey of 20,000 school children.

We rejected semi-quantitative tests such as the agar gell and the filter paper tests as inaccurate, we rejected pilocarpine iontophoresis as too slow, and we concentrated on a chloride-specific ion electrode test, using local heat as the sweating stimulus, because we had found the test to be as accurate as the pilocarpine test and very much faster.[5] In preliminary studies we could test at the rate of 150 patients per hour with a continuous assembly line mass production technique.

We tested 20,071 children in 26 cities around Minnesota. Their average age was eight years. We found only four patients, all previously known to their family doctor. This gave us a prevalence estimate of one case per 5,000 children aged eight years. Since only one-fourth of the patients with cystic fibrosis not receiving special therapy would be expected to live that long, we calculated an incidence estimate of one case in 1,200 newborn infants.[6]

Our conclusions were: (1) that the low prevalence of cystic fibrosis in school-aged children and the failure to find any undiagnosed cases were contraindications to mass screening of all school-aged children. (2) For such older children we recommend sweat testing if any of the cardinal

Research work reported in this paper was supported by a Cystic Fibrosis Care, Research, and Teaching Grant and Special Grants from the National Cystic Fibrosis Research Foundation and by special aid from the Minnesota Mrs. Jaycees.

Dr. Warwick is Associate Professor, Department of Pediatrics, University of Minnesota, Minneapolis, Minnesota.

symptoms of cystic fibrosis appear. When all children with such symptoms are screened, about one child in 100 will be found to have symptomatic cystic fibrosis.[7] (3) That mass screening must be done at an age when most cases would be undiagnosed and when the results of therapy would be most effective, that is, in early infancy, preferably on the newborn infant.[8]

Since 1965 three techniques have been advocated for trials of newborn screening. One of these, a semi-quantitative estimation of the albumin content of meconium, has been adequately tested and discarded.[9]

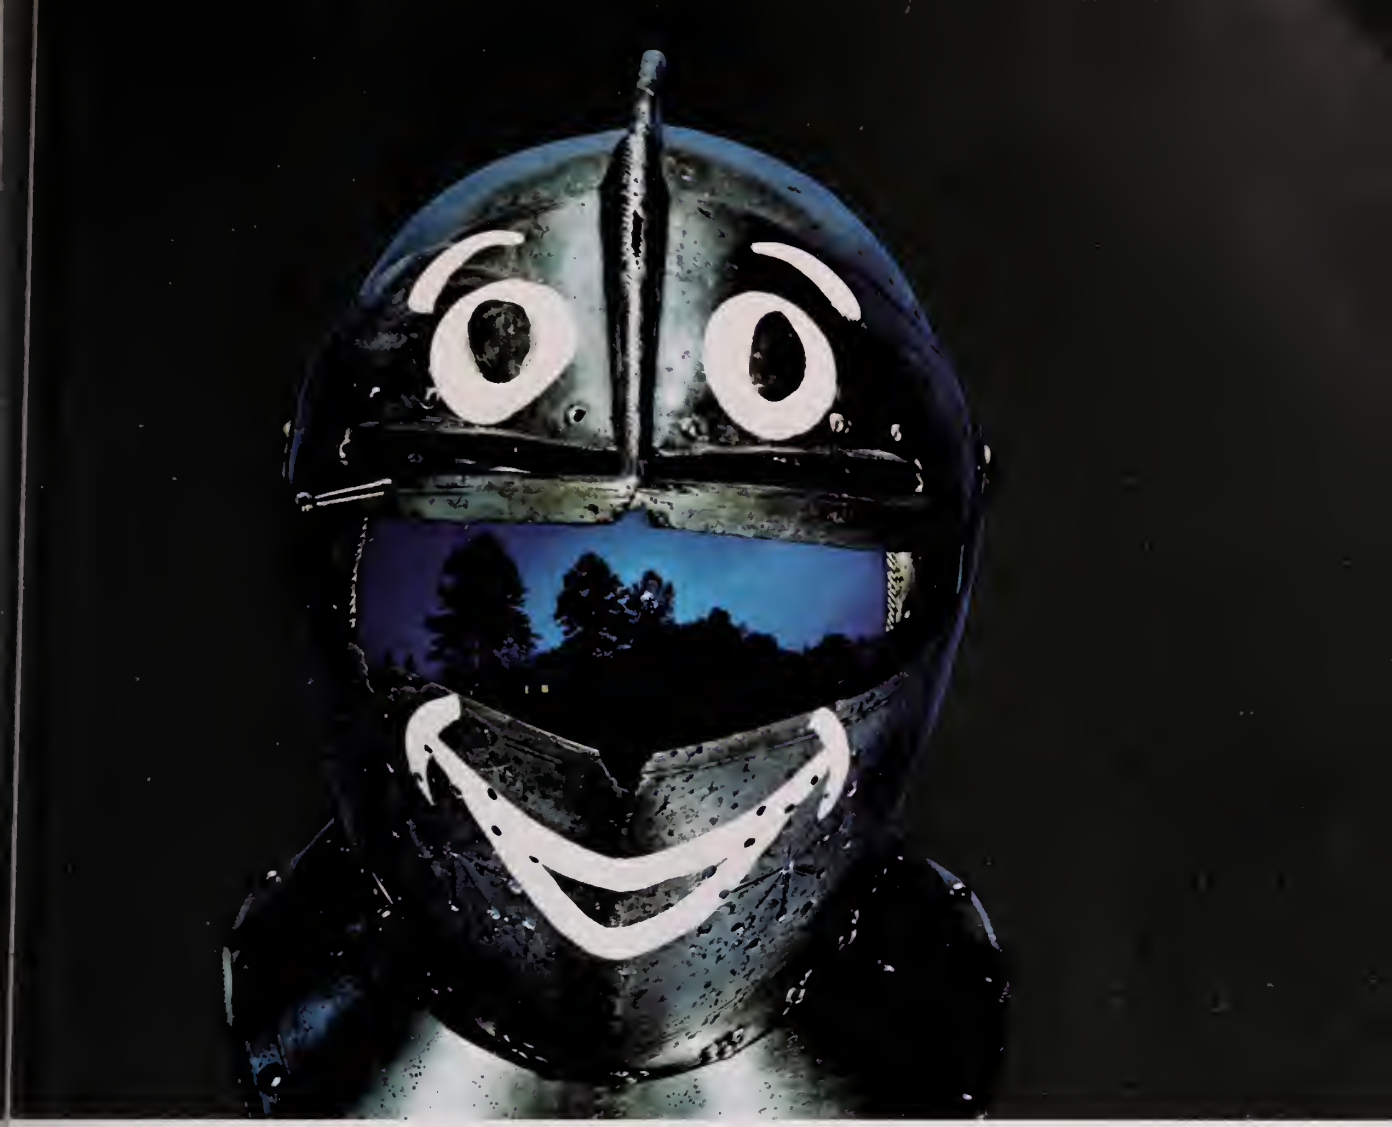
The second, measurement of Na, K and Cl in the clipping of finger or toe nails by neutron activator and scintillation counting, has captured the imagination of many U.S. investigators because it can be automated and because there are enough neutron activators in the U.S. to test nail clippings from all newborns if the test proves successful.[10,11] At present the test is about 85% accurate for diagnosis of cystic fibrosis or diagnosis of normality; but it will require much more work to obtain an acceptable accuracy of 99 percent that can be achieved with conventional sweat tests.

The third approach is to do sweat tests on newborn infants. If such infants are hydrated and warm, adequate sweat can be obtained from them for *in situ* analysis with specific ion electrodes.

With our technique the sweat chloride values found after 24 hours of age are identical with the values we obtain on the same infants at three, six or nine months, at one to three years of age.

Pilocarpine iontophoresis can also be done; and if other simple fast reliable techniques for collection and analysis of sweat can be developed, either technique for screening newborn infants will be sufficiently accurate (99%) and simple enough for feasibility studies of newborn screening.[9]

Equipment is now available for a cooperative study between multiple hospitals to test 40,000 to 60,000 newborn infants.



Summary

The grave prognosis for children with cystic fibrosis can be so improved with more intensive care, especially with prophylactic pulmonary therapy, that many such children can grow to be healthy adults. Screening programs are essential if the diagnosis is to be made prior to the development of unarrestable pulmonary complications. Screening programs for older children should be limited to children with any of the cardinal symptoms of cystic fibrosis. Mass screening of healthy children should be limited to the newborn period of early infancy. The sweat test can now be used to test the feasibility of eventual nation-wide newborn screening programs for cystic fibrosis.

A newborn screening program for cystic fibrosis ought to be started on a pilot scale because: (1) Early diagnosis and treatment can prevent the clinical complications; (2) Tests are available which will efficiently identify the one cystic fibrosis child from among the 1,200 normal newborns; (3) The cost of case finding is minimal compared to existing screening programs for phenylketonuria, and (4) The potential savings to the community through prevention of complications are very great.

Nose clear all knight

For upper respiratory allergies and infections including the common cold, Dimetapp Extentabs® effectively relieve the stuffiness, drip and congestion all night and all day long on just one Extentab every 12 hours. For most patients drowsiness or overstimulation is unlikely.

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg., phenylephrine HCl, 15 mg., phenylpropanolamine HCl, 15 mg

INDICATIONS: Dimetapp Extentabs are indicated for symptomatic relief of allergic manifestations of upper respiratory illnesses, such as the common cold, seasonal allergies, sinusitis, rhinitis, conjunctivitis and otitis. In these cases it quickly reduces inflammatory edema, nasal congestion and excessive upper respiratory secretions, thereby affording relief from nasal stuffiness and postnasal drip.

CONTRAINDICATIONS: Hypersensitivity to antihistamines of the same chemical class. Dimetapp Extentabs are contraindicated during pregnancy and in children under 12 years of age. Because of its drying and thickening effect on the lower respiratory secretions, Dimetapp is not recommended in the treatment of bronchial asthma. Also, Dimetapp Extentabs are contraindicated in concurrent MAO inhibitor therapy.

WARNINGS: *Use in children:* In infants and children particularly, antihistamines in overdosage may produce convulsions and death.

PRECAUTIONS: Administer with care to patients with cardiac or peripheral vascular diseases or hypertension. Until the patient's response has been determined, he should be cautioned against engaging in operations requiring alertness such as driving an automobile, operating machinery, etc. Patients receiving antihistamines should be warned against possible additive effects with CNS depressants such as alcohol, hypnotics, sedatives, tranquilizers, etc.

ADVERSE REACTIONS: Adverse reactions to Dimetapp Extentabs may include hypersensitivity reactions such as rash, urticaria, leukopenia, agranulocytosis and thrombocytopenia; drowsiness, lassitude, giddiness, dryness of the mucous membranes, tightness of the chest, thickening of bronchial secretions, urinary frequency and dysuria, palpitation, hypotension/hypertension, headache, faintness, dizziness, tinnitus, incoordination, visual disturbances, mydriasis, CNS-depressant and (less often) stimulant effect, anorexia, nausea, vomiting, diarrhea, constipation, and epigastric distress.

HOW SUPPLIED: Light blue Extentabs in bottles of 100 and 500.

A·H·ROBINS

A. H. Robins Company
Richmond, Va. 23220

for today's pain...
memory of yesterday's pain...
apprehension over tomorrow's pain–

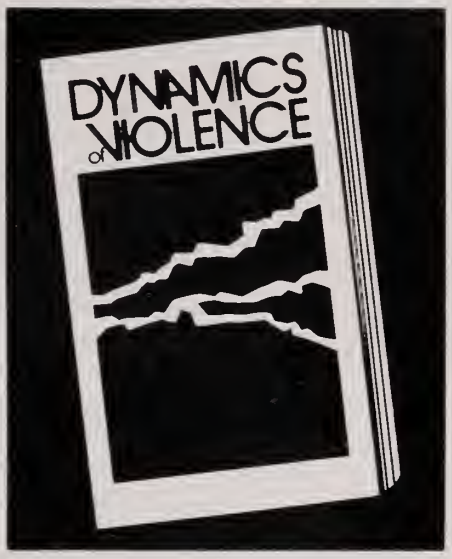
A·H·ROBINS

For the patient with a terminal illness, PAIN past, present, and future can dominate his thoughts until it becomes almost an obsession. The more he is aware of the pain he is now experiencing, the more difficult it is to erase his memory of yesterday's pain, and to allay his fearful anticipation of tomorrow's pain. Surely the last thing this patient needs is an analgesic containing caffeine to stimulate the senses and heighten pain awareness. A far more logical choice is Phenaphen with Codeine. The sensible formula provides ¼ grain of phenobarbital to take the nervous "edge" off, so the rest of the formula can help control the pain more effectively. Don't you agree, Doctor, that psychic distress is an important factor in most of your terminal and long-term convalescent patients?

the analgesic formula that calms instead of caffeinates

Phenaphen® with Codeine

Phenaphen with Codeine No. 2, 3, or 4 contains: Phenobarbital (¼ gr.), 16.2 mg. (warning: may be habit forming); Aspirin (2½ gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Codeine phosphate, ¼ gr. (No. 2), ½ gr. (No. 3) or 1 gr. (No. 4) (warning: may be habit forming).



Indications: Provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. **Contraindications:** Hypersensitivity to any of the components. **Precautions:** As with all phenacetin-containing products, excessive or prolonged use should be avoided. **Side effects:** Side effects are uncommon although nausea, constipation and drowsiness may occur. **Dosage:** Phenaphen No. 2 and No. 3—1 or 2 capsules every 3 to 4 hours as needed; Phenaphen No. 4—1 capsule every 3 to 4 hours as needed. For further details see product literature.

(III) Phenaphen with Codeine is now classified in Schedule III, Controlled Substances Act of 1970. Available on written or oral prescription and may be refilled 5 times within 6 months, unless restricted by state law.

DYNAMICS of VIOLENCE

Brief, brilliant studies drawn from a close, often painful scrutiny of human violence

Jan Fawcett's superbly edited book takes you on an exploration into this age of violence. Nightmarish cases from contemporary history...war, bombings, assassination, mass murder, rape, arson, riots...are the backdrops against which eminent psychiatrists discuss violence and aggression.

Immensely revealing and readable, Dynamics of Violence examines violent aggression in terms of historical and social dimensions in our national history, clinical case studies of violent individuals, and clinical research investigations.

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

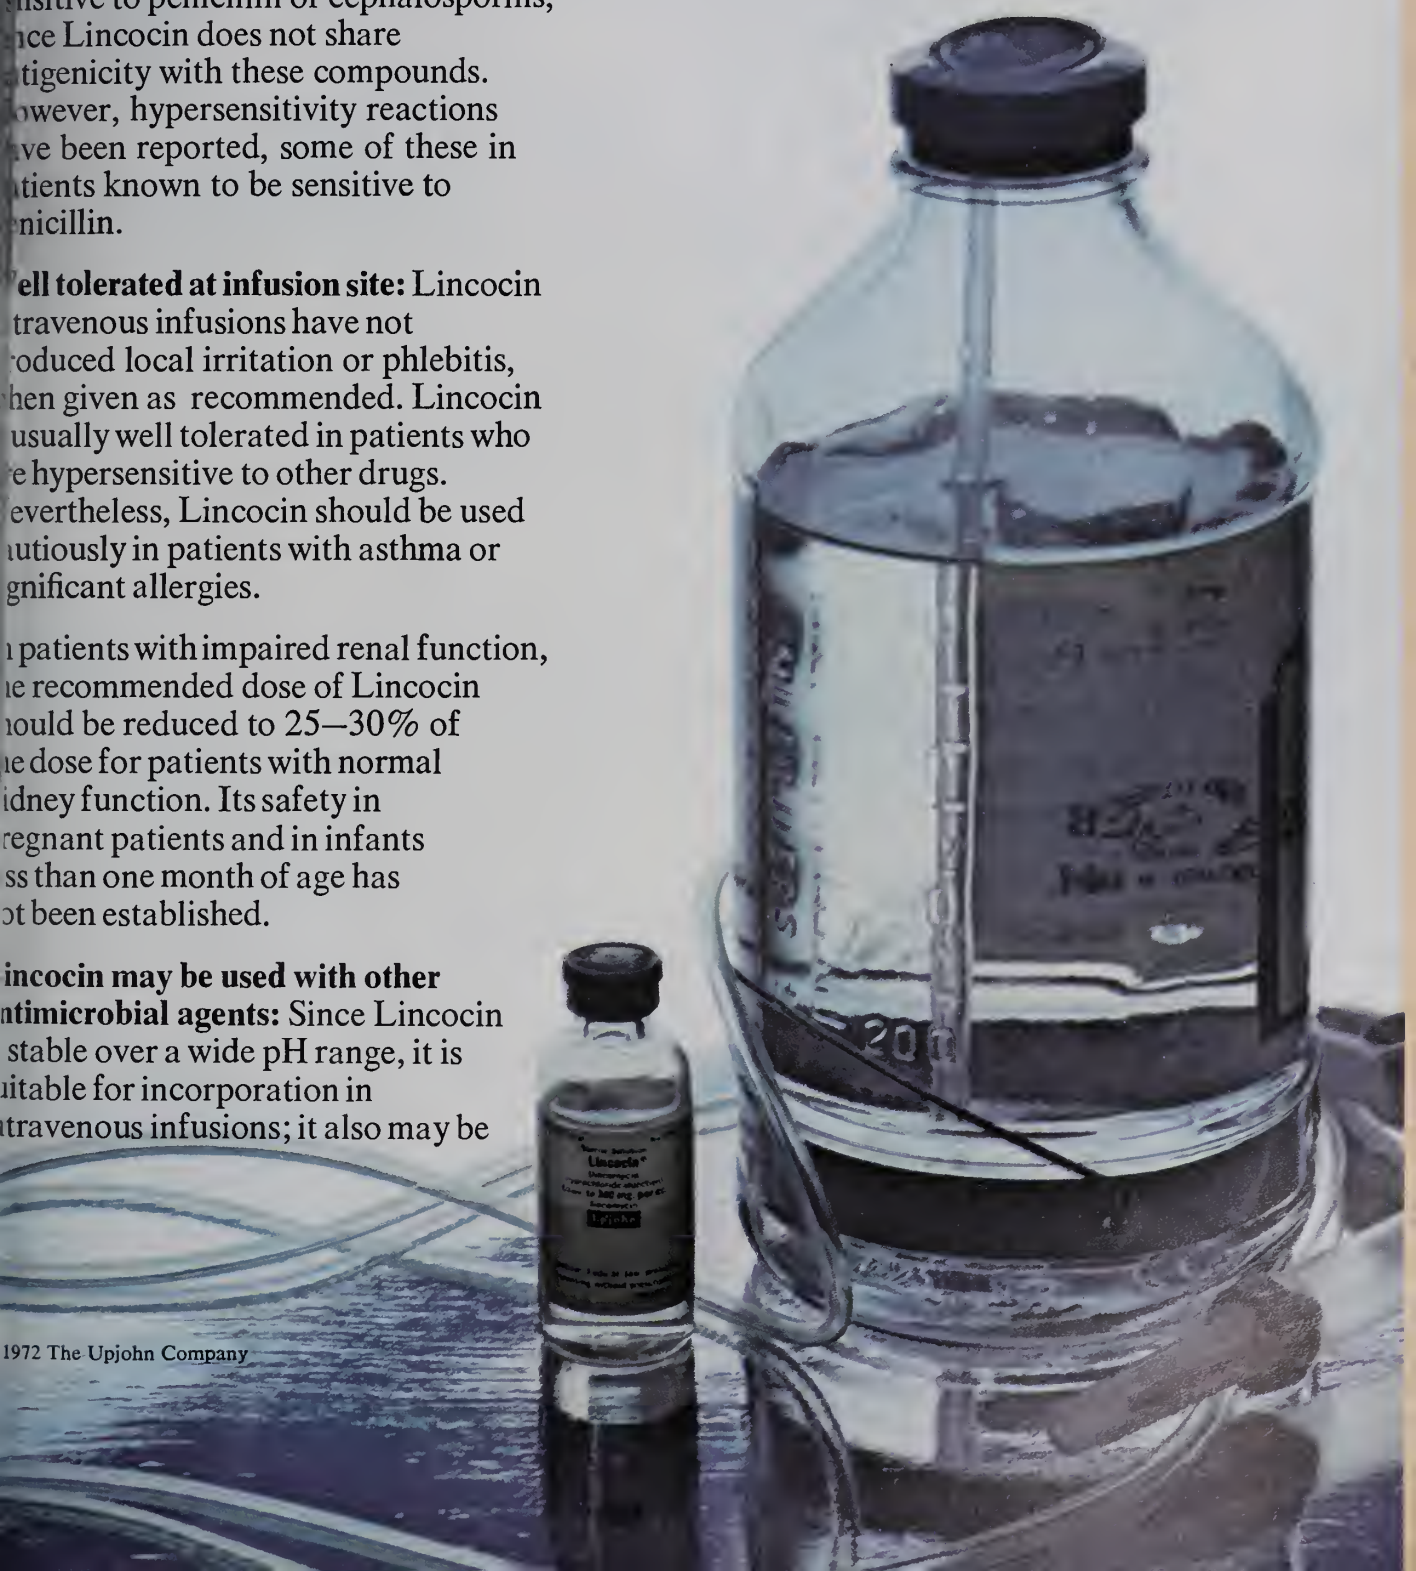
In usual IV doses, Lincocin (lincomyc hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water But when 4 grams or more per day is given, Lincocin should be diluted in n less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

ifections caused by susceptible strains
pneumococci, streptococci, and
aphylococci, including penicillin-
sistant strains. Staphylococcal strains
sistant to Lincocin (lincomycin
drochloride, Upjohn) have been
covered. Before initiating therapy,
lture and susceptibility studies should
performed. Lincocin has proved
luable in treating patients hyper-
nsitive to penicillin or cephalosporins,
nce Lincocin does not share
tigenicity with these compounds.
owever, hypersensitivity reactions
ve been reported, some of these in
tients known to be sensitive to
nicillin.

ell tolerated at infusion site: Lincocin
travenous infusions have not
oduced local irritation or phlebitis,
hen given as recommended. Lincocin
usually well tolerated in patients who
e hypersensitive to other drugs.
evertheless, Lincocin should be used
utiously in patients with asthma or
gnificant allergies.

patients with impaired renal function,
ie recommended dose of Lincocin
ould be reduced to 25—30% of
ie dose for patients with normal
idney function. Its safety in
regnant patients and in infants
ss than one month of age has
ot been established.



incocin may be used with other
ntimicrobial agents: Since Lincocin
stable over a wide pH range, it is
uitable for incorporation in
travenous infusions; it also may be
administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

1972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatm *Skin and mucous membranes*—Skin ras urticaria, vaginitis, and rare instances of exfoliative and vesiculobullous dermatitis h been reported. *Liver*—Although no direc lationship to liver dysfunction is establis jaundice and abnormal liver function (particularly serum transaminase) have observed in a few instances. *Cardiovasc* —Instances of hypotension following pa teral administration have been repor particularly after too rapid IV admini tion. Rare instances of cardiopulmonary rest have been reported after too rapid administration. If 4.0 grams or more ad istered IV, dilute in 500 ml of fluid administer no faster than 100 ml per h *Special senses*—Tinnitus and vertigo h been reported occasionally. *Local react* —Excellent local tolerance demonstrate intramuscularly administered Linco (lincomycin hydrochloride). Reports of following injection have been infrequ Intravenous administration of Lincoci 250 to 500 ml of 5% glucose in dist water or normal saline has produced local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500* Capsules—bottles of 24 and 100. *St Solution, 300 mg per ml*—2 and 10 ml and 2 ml syringe. *Syrup, 250 mg per* —60 ml and pint bottles.

Case Report

Concurrence of Achalasia

with Adenocarcinoma of the Stomach

REX B. SHAFER, M.D. AND JOHN R. JACOBSON, M.D.

Achalasia is a disorder of esophageal motility characterized by esophageal dilatation with absence of effective propulsive movements and failure of relaxation of the lower esophageal segment. The cause of achalasia is unknown, though many consider it to be of neural origin. Microscopic examination of the esophagus with achalasia reveals fewer ganglion cells than normal in Auerbach's plexus.[1-3] The reduction of ganglion cells is more pronounced in the body of the esophagus and to a lesser extent in the lower sphincter. The precise nature of the autonomic neural lesion has not been agreed upon.

Incidence

Carcinoma of the esophagus occurs with a definite increased incidence in patients with achalasia. This incidence of carcinoma has been reported to vary from one to 20%.[4-6] The most quoted incidence of 3% is probably accurate.[4] Histologically, squamous cell carcinoma has been found in essentially all instances. Only infrequently has adenocarcinoma been described, and then arising from the esophagus. The concurrence of achalasia with adenocarcinoma of the stomach is extremely rare.

Purpose

The following case is reported to re-emphasize the association of carcinoma with achalasia and more specifically to report the association of adenocarcinoma of the stomach with achalasia. Attention is drawn to the delay in recognition of the malignancy because of the presence of achalasia and its associated signs and symptoms.

From the Department of Medicine, University of Minnesota, Minneapolis, Minn., and Minneapolis Veterans Hospital, Minneapolis, Minnesota.

Reprint requests to Nuclear Medicine Service, Veterans Administration Hospital, Minneapolis, Minnesota 55417 (Dr. Shafer).

Case Report

A 40-year-old white male with a history of congenital achalasia, symptomatic since age six, was referred to the Minneapolis Veterans Administration Hospital because of abrupt onset of abdominal pain with melena and sudden hematemesis. History included the onset of substernal pain and difficulty swallowing at age six. Diagnosis of cardiospasm was made from the clinical history and typical x-ray changes.

Early Treatment

The patient was treated with dilatations which afforded little relief. He remained symptomatic through childhood, but learned to force food from the esophagus into the stomach by swallowing air. At age 20 he was re-evaluated at the Hines Veterans Administration Hospital and underwent an esophago-gastrostomy with a Heller myotomy.

He experienced significant clinical improvement and

Fig. 1—Barium swallow reveals dilated esophagus, showing typical conical narrowing of the lower segment.

Fig. 2—Upper gastrointestinal Xrays with contrast material in the dilated esophagus, shows filling defect (arrow) involving the cardia of the stomach.

Fig. 3—Gross autopsy specimen demonstrating: (1) dilated esophagus, (2) gastroesophageal junction, and (3) cardia and body of the stomach. The nodular serosa of the cardia of the stomach is identified (arrow).

remained asymptomatic until ten years later when he noted onset of gastrointestinal bleeding and melena. Esophagoscopy at that time demonstrated severe esophagitis. Surgery was recommended but was refused by the patient.

Present Illness

Conservative management with diet and dilatation was instituted. This therapy was reasonably effective until December, 1970 when at age 39 the patient experienced marked increase in dysphagia with associated 25 pound weight loss. In July, 1971, he was hospitalized at a local hospital where examination and biopsy of a supraclavicular lymph node established the diagnosis of metastatic adenocarcinoma. Esophagoscopy revealed a constriction of the lower esophagus near the gastrointestinal junction, with a fibrous mucosa which suggested carcinoma. The stomach was not entered. An upper gastrointestinal series was obtained and showed a mass involving the cardia of the stomach, as well as constriction and narrowing of the lower esophagus (Figure 1 and 2). Because of the obvious metastatic extension of the carcinoma, no surgery was performed. The patient was discharged and later admitted to this institution following the abrupt onset of abdominal pain and melena.

Physical and Laboratory Results

On presentation here, he was a pale, anxious white man with evidence of recent weight loss. Vital signs were unremarkable. A hard, nodular mass was present over the left supraclavicular area of previous biopsy scar. The liver was enlarged and palpable three finger-breadths below the right costal margin. The stool was guaiac positive. Laboratory values including a complete blood count, urinalysis, serum electrolytes and an SMA-12 survey were unremarkable except for an alkaline phosphatase of 65 King-Armstrong units (normal 4-17) and a serum glutamic-oxaloacetic transaminase of 300 Babson units (normal 10-40).

Management and Course

Initially, the patient's gastrointestinal bleeding was managed with intravenous hydration, nasogastric suction, and gastric lavage. The patient was treated symptomatically. He died after twelve days in the hospital.

Autopsy

At postmortem examination, the esophagus was dilated throughout its entirety, measuring six cm in diameter at its mid-portion. Immediately above the gastro-esophageal junction, there was focal thickening with a ragged mucosa, but no ulceration or infiltration of the esophageal wall. The esophagogastric lumen was markedly narrowed and two tracts passed from the esophagus into the stomach. The cardia of the stomach was thickened with nodular serosa, the largest nodule of which measured four cm in greatest dimension (Figure 3). The lungs, liver and mediastinal lymph nodes were all grossly involved with tumor. The liver was large, extending eight cm above the xiphoid and seven cm below the right costal margin, and there were numerous nodules present on its surface. Histologic sections of the tumor from the cardia of the stomach, lungs, liver and medias-

ial nodes all contained undifferentiated adenocarcinoma (Figure 4).

Discussion

Thomas Willis first reported achalasia in 1679.[7] n 1872 Fagge described a patient with carcinoma eveloping in a dilated esophagus presumed to be halasia.[8] Since then, there have been numerous oradic case reports of the coexistence of carnoma and achalasia. Unfortunately, disparate gures persist regarding the exact incidence of is association. In a most recent review of the bject by Just-Viera and Haight in 1969, a total f 167 patients with achalasia and carcinoma ere reviewed.[4] This represents a summation of ne reported world's literature.

The incidence of the coexistence of achalasia nd carcinoma of the esophagus has been reported o be from 1 to 20%. The usual figure of 3% or the incidence of the coexistence of these two liseases seems reasonable.[4,5] This figure is dependent upon the duration of follow-up observation because carcinoma does not develop until nany years after the onset of symptoms and diagnosis of achalasia. Williams reported an average apse time of 18 years between the onset of symptoms due to achalasia and carcinoma detection.[9] In some instances this interval has been as long as forty years. For this reason, a series weighted with patients having achalasia for a much longer duration would show a higher incidence of carcinoma.

Squamous Cell vs. Adenocarcinoma

Most reports incriminate squamous cell carcinoma of the esophagus as the most common malignant tumor accompanying achalasia.[4-6,10] Only a single example of adenocarcinoma localized to the cardia of the stomach was included in the review of Just-Viera and Haight.[4] This histological type is only infrequently associated with achalasia because the predominant primary site of the neoplasm is the esophagus, not the stomach.

Theories

There have been multiple theories proposed as to why achalasia might predispose to malignancy. Fleiner initially suggested that the trauma of repeated tube bouginage in patients with achalasia might lead to the malignant transformation.[11] Rake postulated that the carcinomatous transformation seen may result from necrotic irritation of the esophageal mucosa caused by retained foodstuffs and saliva.[12] He drew the comparison of this process to the malignant transformations seen in patients with long-standing ulcerative colitis. Virno and Carboni reinforced the belief of most authors supporting the view that carcinoma is a result of local chronic irritation that is present in achalasia.[13] They proposed that an initial stage of muscular hypertrophy was seen early in the disease which subsequently was followed by esophageal dilatation and then retention of the esophageal contents. This resulted in a change in the character of the esophageal wall, which permitted increased bacterial growth and continuous

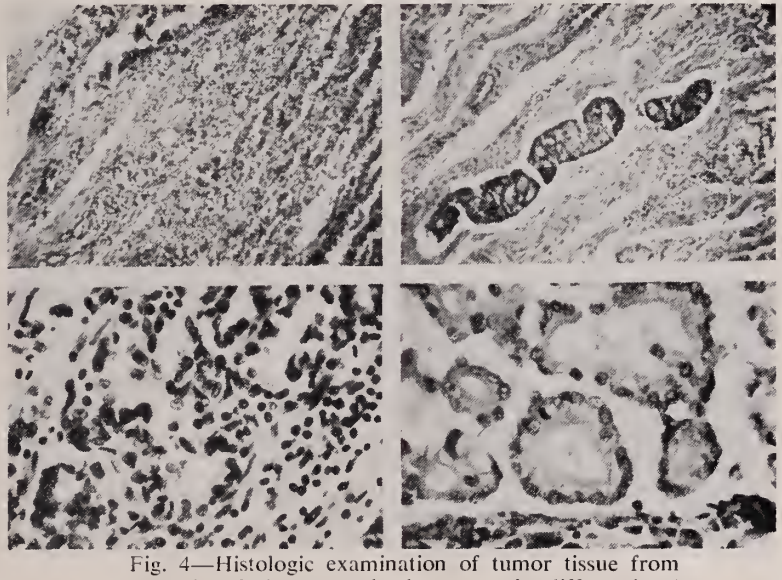

Fig. 4—Histologic examination of tumor tissue from the cardia of the stomach shows poorly differentiated adenocarcinoma.

chemical irritation from retained, decomposing food. The resultant chronic esophagitis then becomes the fertile ground for metaplasia of the epithelium to occur. Neither the trauma of repeated bouginage or the chronic irritation caused by retained foods could be implicated logically in the association of achalasia with adenocarcinoma of the cardia of the stomach. The same motility dysfunction involving the esophagus may also have involved the epithelium of the gastric cardia.

Management

If these theories are correct and stasis and chronic irritation contribute to the incidence of malignant degeneration, then prompt management eliminating stasis would reduce the occurrence of carcinoma. The findings reported by Wychulis et al. from the Mayo Clinic support the impression that there is reduced incidence of carcinoma in patients who have had early surgical treatment by esophagogastric myotomy.[6] This results in a more effective prophylactic measure to control retention of esophagitis and it is believed by them to reduce the incidence of premalignant changes. Le Roux and Wright refute this point and feel that if the drainage procedure is not complete, the potential for development of carcinoma may be even greater.[14]

The consensus of opinion from the literature then is that if early and adequate surgical intervention is performed and the patient is relieved of symptoms, there is probably a reduction in the incidence of carcinoma. In our patient there was a 20-year interval after his Heller myotomy before the diagnosis of carcinoma, although he had been symptomatic for the ten years prior to this diagnosis.

Recognition of the malignant potential in a patient with achalasia demands that he have regular, periodic examinations. There exists at lea three reasons for delay in recognition of mali nancy in the patient with achalasia: (1) the patie with achalasia is already accustomed to episod of dysphagia and with the onset or recurrence this symptom, he does not seek early medical a tention, (2) there is difficulty in x-ray diagnosis the malignant lesion because of the long-standir changes of achalasia and possible previous oper tive procedures, and (3) because of the dilat cardio-esophageal junction, considerable extensic of the malignancy has to occur before there obstruction of the lower esophagus and seriou symptoms of dysphagia with regurgitation.

Conclusion

While the co-existence of achalasia with squan ous cell carcinoma of the esophagus has been r ported, the concurrence of achalasia and carcin ma of the stomach is extremely rare. Similarit in etiology including race, age and duration symptoms are common to both malignant lesion Whether relief of stasis by an esophageal myotom delays malignant degeneration, or whether the d generation occurs as a natural sequence of th lesion is unknown. Certainly, the difficulty i early diagnosis of malignant change was compl cated by the previous diagnosis of achalasia. Be cause of recurrent episodes of dysphagia, the pa tient did not seek early medical advice. Onc examined, the dilated cardio-esophageal junctio was not initially interpreted as malignant becaus of the changes of achalasia and previous surgica intervention. Finally, demonstration of a malig nant mass involving the cardia of the stomach wa accomplished by x-ray diagnosis, esophagoscop gastroscopy and biopsy.

Fracture Conference

The Thumb Metacarpophalangeal Joint

Injuries

RONALD L. LINSCHEID, M.D., R. WAYNE GRAINGER, M.D. AND
EINER W. JOHNSON, JR., M.D.

Dr. Wayne Grainger:

This conference is concerned with injuries to the ligaments of the metacarpophalangeal joint of the thumb. Stability of this joint depends on the radial and ulnar collateral ligaments which run from the first metacarpal to the proximal phalanx. A force deviating the phalanx ulnarly or radially may tear the ligament on the opposite side or avulse its bony attachment. If the injury is ignored or treated improperly, instability of the metacarpophalangeal joint results, producing pain and weakness on pinching motion of the thumb.

The first patient was a 22-year-old nurse who dislocated the metacarpophalangeal joint of her right thumb while skiing, and this was reportedly reduced by the ski patrol at the site. When she was seen here, she had tenderness, swelling, ecchymosis, and slight radial deviation of the metacarpophalangeal joint. Figure 1 shows the roentgenogram made about 36 hours after the injury.

Dr. Wayne E. Janda:

There is a slightly displaced avulsion fracture at the ulnovolar aspect of the proximal phalanx of the thumb. This is presumably from an abduction sprain of the joint and may indicate injury to the ulnar collateral ligament or its insertion. There is also a suggestion of volar subluxation of the joint.

Dr. Grainger:

The second patient was a 35-year-old male physician who sustained a dislocation of the metacarpophalangeal joint of the thumb when the starting cord of his lawn mower flew back and twisted his thumb. He noted then that *at that time* his thumb was in slight ulnar deviation at the metacarpophalangeal joint. Figure 2 shows the roentgenogram made when he was seen here.

Dr. Matko Milicic:

There is ulnar deviation of the proximal phalanx. I would suspect that the radial collateral ligament has been injured. The injured collateral ligament might be repaired to ensure adequate reduction and late stability, although casting for four weeks is an acceptable alternative.

Fig. 1 (Case 1)—Postreduction film of 22-year-old nurse who dislocated thumb metacarpophalangeal joint, showing avulsion of small articular fragment with insertion of ulnar collateral ligament. Slight volar subluxation persists.

Drs. Linscheid and Johnson are in the Section of Orthopedic Surgery, Mayo Clinic and Mayo Foundation.
Dr. Grainger is a Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.
Fracture Conference, May 12, 1969.

Dr. Grainger:

Does the roentgenographic appearance make any difference in your proposed treatment?

Dr. Milicic:

The physical examination to assess unusual mobility at the joint is as important as the roentgenogram. Stress roentgenograms should be made of both thumbs to demonstrate the degree of ligamentous laxity or rupture. Local anesthetic instilled sterilely into the joint may be necessary to achieve this. There is also an obvious small avulsion fracture on the ulnar aspect of the joint, which appears to be a margin of joint surface avulsed with the dislocation. In this instance, however, this is of less importance than the radial collateral ligament injury.

Dr. Grainger:

In both instances the thumb was deviated to relax the involved ligament, and small gauntlet casts were applied. The first patient, the nurse, wore the cast for three weeks. She was seen one week after cast removal and had satisfactory maintenance of the reduced position and good stability and pinch without pain. The second patient managed himself and was lost to follow-up. We will have to get the follow-up from Dr. Linscheid.

Dr. Ronald Linscheid:

He has a stable, painless thumb and is doing very well. Injury to the ulnar collateral ligament may represent a partial tear or a complete rupture. A distinction should be made because open reduction is indicated in the latter case. The necessity of this has been explained and emphasized by Stener.[1] When the ulnar collateral ligament is torn by marked radial deviation, the avulsion occurs at the insertion at the base of the proximal phalanx. The proximal margin of the extensor mechanism is pulled distally with the thumb and slides over the raw end of the collateral ligament. When the thumb recoils, the extensor margin retracts the ligament away from the site of avulsion. Thus prevented from spontaneous healing, the joint remains unstable and insecure.

Dr. Mark B. Coventry:

Last month I saw a patient, a man about 23 years old, with this deformity untreated initially and with marked disability with relaxation of the metacarpophalangeal joint of the thumb. Not knowing what else to do, we decided to perform arthrodesis of the joint. He was a student, and even holding a pen to write his examination pap was painful and difficult. Another patient wi similar history and findings had been treated the same fashion several years before. I presun from my experience with two cases that it is muc

Fig. 2—(Case 2)—Self-reduced subluxation of thum metacarpophalangeal joint. Despite fragment of bone o ulnar margin of joint, there was ulnar deviation o thumb, tenderness, and instability of radial collateral lig ament.

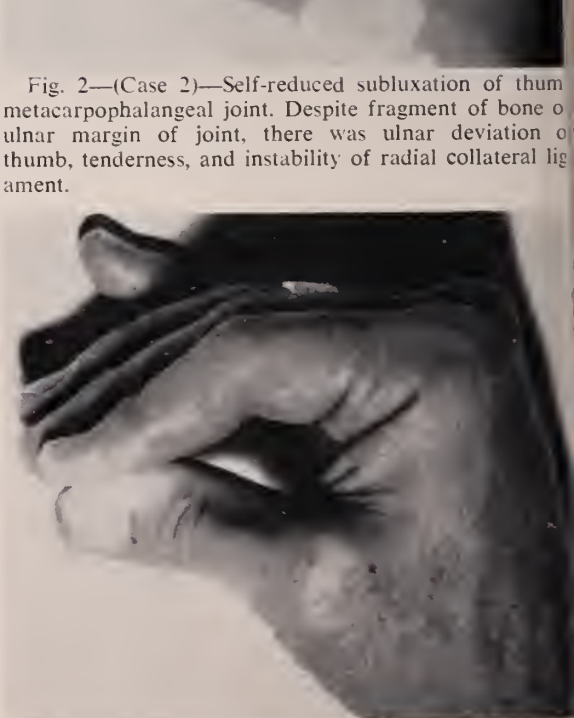

Fig. 3—Unstable ulnar collateral ligament in 33-year old orthopedist.

better to treat these positively and adequately rather than as late complications.

Dr. Linscheid:

We do not commonly see this injury. An unstable thumb may result when either the radial or the ulnar collateral ligament of the metacarpophalangeal joint is sufficiently injured, although the latter is of greater significance.

Dr. Grainger:

My own thumb was treated conservatively 13 years ago. I wish it had been operated on. It is unstable (Figure 3) and has been a nuisance, especially in doing fracture manipulations.

Dr. Edward M. Tapper:

The same injury in a younger person produces an epiphyseal separation rather than a collateral ligament rupture.

Dr. Linscheid:

We were just going to show that. A 12-year-old girl with hypermobile joints sprained her thumb while turning cartwheels. A stress view of the thumb is shown in Figure 4. There was point tenderness directly over the ulnar collateral ligament, and radial abduction was significantly greater in the injured than in the noninjured thumb. Dr. Dobyns explored this injury and found a type I epiphyseal fracture: a fracture entirely through the cartilaginous portion of the growth plate. Healing was uneventful with cast fixation. I apparently did not stress this thumb sufficiently to demonstrate it on the roentgenogram.

Dr. Tapper: This is a common skiing injury.

Dr. Linscheid:

Yes. When skiers slip a hand through the wrist strap to grasp the pole, many tend to twist the strap around the radial border of the thumb. Thus, if they fall, the strap tends to adduct the thumb ulnarly over the handle of the pole or may act as a fulcrum to the radial aspect and aid ulnar collateral ligament injury. Soreness of this joint is extremely common in skiers.

Dr. James H. Dobyns:

Water-skiing is an even more significant cause of serious injury to the thumb; I have seen three thumbs completely avulsed by the tow rope. I favor aggressive treatment in the matter of sprains. Flexibility of the thumb at the metacarpophalangeal joint is not nearly as important as stability of the thumb at this joint. I agree with Dr. Coventry; one sees many patients with thumbs disabled by injuries that produce instability and weakness because of rupture of the collateral ligaments.

Fig. 4 (Case 3)—Type I epiphyseal separation in 12-year-old girl. Torn ulnar collateral ligament was suspected. Stress film failed to open the epiphyseal separation which was obvious at operation.

Dr. Linscheid:

These three cases illustrate the effect of a force that deviates the phalanx from the long axis of the metacarpal of the thumb. After epiphyseal closure, rupture of one of the collateral ligaments results. If left untreated, these thumbs are weak, unstable, painful, and disabling. Often, arthrodesis of the joint is the only subsequent treatment left.

We believe that vigorous initial treatment is indicated. In some instances this means open reduction and accurate replacement or repair of the avulsed or parted ligament. With lesser injuries, reduction and casting are sufficient. Adequate fixation for the necessary time is also an

important factor, with a minimum of three weeks.

Prior to epiphyseal closure, separation of the proximal phalangeal epiphysis often results from this same force. Manipulative reduction is most often the successful means of treatment.

Historic Hospitals

Arab Hospital Architecture

Courtyard of the Nuri Hospital at Damascus, built in the twelfth century. Herzfeld, Ars Islamica, IX: 1, 1942.

The Arabs built their early hospitals in population centers for maximum availability to the people. They conceived of hospitals as refuges from the crowding of the surrounding city where the sick could find peace and comfort as well as treatment. The central courtyard, the most characteristic architectural feature, was said to be modelled after the Prophet's simple home at Medina. Mohammed's advice against elaborate and costly buildings was widely disregarded, however, as ambitious builders produced structures of ever greater dimensions and more grandiose conception.

The first of their hospitals was built at Baghdad of sun-dried mud brick. As the center of the culture shifted to Damascus and Cairo the humble material gave way to limestone, granite, and marble. The typical floor plan consisted of four high-ceilinged arcades arranged in the form of a cross with the courtyard at its center. Each arcade, open on the side facing the courtyard, was subdivided into rooms, or iwans, used for wards, examining rooms, and the many special purposes required by a hospital. The complex subdivision made it possible to segregate the patients by sex and by the nature of their disease. In the late Middle Ages the specialized wards were attended by physicians of appropriately specialized training and interest.

Many of the arcades included fountains with running water draining by aqueducts into the pool at the center of the courtyard. Because of their desert origin the Arabs found special comfort and security in freely flowing water; even the earliest Baghdad hospitals made use of its esthetic value and cooling effect. In colder regions such as Anatolia the same general plan was followed except that the central courtyard was covered over by a vaulted masonry ceiling.

Alcoholism

Hospital Treatment of Alcoholism

A New Therapeutic Concept

GEORGE MANN, M.D.

We in the medical profession hold the philosophic attitude that we will care for all persons who have medical problems regardless of their nature. Persons with certain illnesses, however, have a difficult time receiving medical care. The alcoholic clearly exemplifies this defect in medical care. His disease is destructive to himself, his family, and his social environment.

Three years ago, we at St. Mary's Hospital decided to try to help the individual and society by providing care for the alcoholic. We wanted to show that a private general community hospital could effectively care for and rehabilitate alcoholics. Alcoholics are ubiquitous in our hospital population. Traditionally we treat alcohol complications in medical and surgical units. The emotional complications have been treated in our psychiatric units.

But nowhere in the general hospital has it been possible for the alcoholic to receive care for the etiologic process that produces these complications. Our basic premise is this: alcoholism can be diagnosed in its early stages and proper therapeutic and rehabilitative efforts can be made to forestall medical complications and to return the alcoholic to society as a functioning responsible person. Our present system of medical education largely ignores this concept of the disease. There is extensive information available to the student in diagnosing and treating alcohol-caused problems of the liver, pancreas, brain, etc., but little didactic or clinical experience in the basic disease process. As a result the focus in medicine today is not on early diagnosis and treatment, but rather on relief of symptoms and therapy for complications.

Dr. Mann is Medical Director, Alcoholism Unit, St. Mary's Hospital, Minneapolis, Minnesota. (Also see page 1020.)

Given as part of a Symposium on the "Treatment of the Hospitalized Alcoholic" which was presented to the combined meeting of the Mayo Clinic Staff and the Zumbro Valley Medical Society on November 4, 1970.

The general community hospital possesses within its institutional structure individuals who can be used effectively in the care of the alcoholic patient. For these people to use their backgrounds efficiently it is necessary to add to the hospital staff others who are expert in the general field of alcoholism and chemical dependency. They can act in ways that enable others in the hospital to focus on this process in a more realistic way than has been done traditionally.

The alcoholic has developed a pattern that affects him in most vital areas of his existence. He must be considered as an individual who is sick physically, emotionally, intellectually, socially, and spiritually. This process envelops the entire human being.

In order, then, to restore this individual to a functional level, therapy must be directed to all five of these areas—hence, the concept of a multidisciplinary approach to treatment. It is our belief that the patient has the best opportunity to achieve the necessary goals for his rehabilitation when the medical staff, nursing staff, counseling staff, clergy, dedicated laymen, and recovered alcoholics all function together in a spirit of equality and teamwork.

There is embodied in the previous statement the concept upon which effective treatment in this area pivots. This concept is that the traditional lines of authority and classic ways of communicating within the hospital structure must be altered. The multidisciplinary approach dictates that professional, paraprofessional, clerical, and lay therapists must all assume co-responsibility, for the overall good of the patient.

We physicians seem to be one of the most conservative groups in our society. The alteration of this way of behaving entails a change of attitude and a willingness to risk some personal involvement with persons who have not yet been included in the spectrum of professionalism in other areas.

I cannot emphasize too strongly the need for the production of an environment which will provide the staff with the greatest degree of freedom to act responsibly and to communicate with each other on an open peer level.

Results

The only way a unit such as ours can justify its existence is by objectively reporting the positive results of such a program. At this point we have been treating patients for two years. Our results are as follows: about 60% of our patients, upon completion of their inhospital therapy, move into our outpatient program, become involved with Alcoholics Anonymous, and stay sober. About 20% of the patients experiment one or more times with alcohol or drugs for relatively brief periods of time, but remain involved in the outpatient program and continue to make efforts to alter their behavior patterns and become more responsible. The remaining 20% lapse into their old behavior patterns, but even among these, because of their experience in treatment and their families' experience in what can be done with others, a high percentage are returned for subsequent treatment either to our hospital or some other institution for therapy.

High on the list of beneficial results must be placed the help that is afforded the family of the patient, whether the patient is able to achieve independence from chemicals or not. In many cases, for the first time in years, the family develops insight into the alcoholic and also an understanding of the role that they play in this disease process. Another great therapeutic result we see is that almost 90% of our outpatients are returned to productive employment or resumption of interrupted educational processes. The ultimate benefit of this to the community cannot be estimated.

At this time we have treated 559 patients; although this is not a great number compared to the estimated 60,000 alcoholics in Hennepin County alone, it is a sufficient number to conclude that the efforts being made in our unit can produce an impact in our community that will be beneficial in areas of employment, traffic accidents, legal procedures, divorce, delinquency, financial stability, community responsibility and other areas that are eroded by this destructive disease process known as alcoholism.

Crippled Children Services

Multidisciplinary Workshops—1972-73

The following Workshops have been arranged for physicians, nurses, teachers, psychologists, speech therapists, social workers and others working with children with a handicap.

No registration fee will be charged. Registration is at 8:30 a.m. unless specified.

Learning Disabilities

A panel consisting of a pediatric neurologist, occupational therapist, speech pathologist and clinical psychologist will discuss the evaluation and treatment of children with learning disabilities.

Various tests and procedures used to identify and evaluate children with learning difficulties will be discusssed by each discipline. Suggestions will be provided for helping a learning disabled child function in a regular classroom. Actual cases will be staffed by the team and there will also be an opportunity for small group discussion with each discipline.

Verapamil

An Anti-anginal Agent

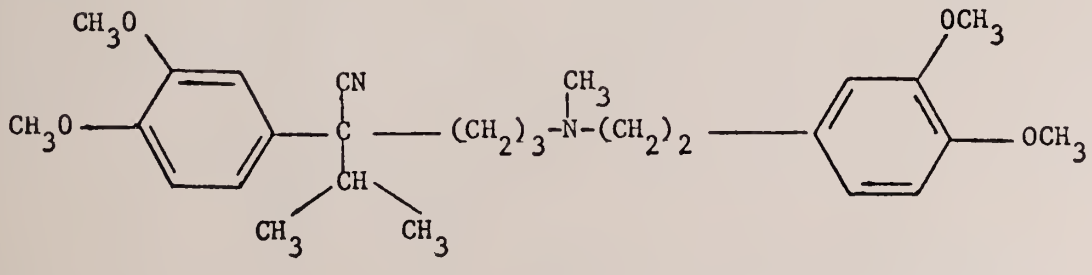
RICHARD R. MOYER, M.D.

AN ORIGINAL PROTOCOL was designed and followed in an attempt to evaluate the therapeutic value of verapamil in a double-blind clinical trial.

Verapamil is α-isopropyl-α-S-(N-methyl-N-homo-veratryl)-α-aminopropyl)-3, 4-dimethoxyphenylacetonitrile and has the structural formula shown in the Figure.

Haas and Hartfelder found the following pharmacologic effects in dogs in lower doses: (1) increased coronary blood flow; (2) increased oxygen saturation of coronary sinus blood with decreased cardiac arteriovenous oxygen differences; (3) variable changes in 0_2 uptake by myocardium.[1]

Higher doses caused lowering of arterial pressure, bradycardia, and decreased myocardial contractility. The difference between the therapeutic and toxic doses was wide. Clinical reports have indicated that verapamil is effective in the treatment of angina.[2]



Method of Study

After a one month rapport single-blind period, a double-blind crossover study was performed to determine the efficacy of verapamil hydrochloride (80mg) in comparison with placebo, in reducing the frequency of reported attacks of exertional angina and nitroglycerin tablets required for its relief. Each patient acted as his own control. The same kind and number of observations were made both in the drug and in the control periods and for the same duration.

Cooperative patients, with objective criteria confirming the diagnosis of angina pectoris (characteristic symptoms plus positive double Master's two-step test, documented history of myocardial infarction, coronary angiogram, or characteristic resting electrocardiogram) with more than five attacks per week, volunteered to participate in this study. Patients who improved by more than 50% reduction in number of attacks while on placebo during the initial rapport period and patients who did not improve on nitroglycerin were rejected from the study. Patients receiving other experimental drugs or experimental therapies for angina or other conditions were excluded.

Twenty-five patients with confirmed angina pectoris secondary to documented coronary arteriosclerosis were studied. In the classification of the New York Heart Association, all were graded Functional Class III (marked limitation of physical activity) or Class IV (inability to carry on any physical activity without discomfort). Patients with angina due to other causes, e.g. aortic stenosis and insufficiency, or arteriovenous fistula were not included in this study. Coronary arteriosclerosis complicated by systemic hypertension in excess of 110 mm HG diastolic was excluded. Patients with

Dr. Moyer is associated with the Mesaba Clinic, Hibbing, Minnesota.

Figure

other systemic diseases which would make the interpretation of the pain difficult—as angina associated with gallbladder stones, hiatus hernia, or duodenal ulcer—were rejected. Patients with depressed sensorium due to narcotics, sedatives, or tranquilizers were excluded. There was no upper age limit, but patients with severe cerebrovascular disease and chronic brain syndrome were excluded because in such patients the evaluation of the anginal response to therapy is difficult.

The frequency of attacks of anginal pain and the number of nitroglycerine tablets required to remain comfortable (not symptom-free) were counted. Other non-quantitative characteristics of angina such as changes in character, intensity, exercise tolerance, and anatomic distribution were also evaluated. Any changes in the patient's emotional state, environment, marital, or occupational status which accounted for a change in the patient's angina were recorded. Efficacy was assessed by statistically significant quantitative changes or consistent subjective improvement affecting the clinical picture of the disease.

Results

Twenty-five patients with angina pectoris due to arteriosclerosis and who had evidence of a previous myocardial infarction were studied. Fourteen were male and eleven were female. The mean age was 63.8 years and the range was 45 to 91 years. The dose of verapamil was 80 mg q.i.d.

Minor adverse reactions occurred in nine of the patients while on verapamil and three of the patients while on placebo. In no instance was the drug discontinued because of side effects. Constipation, dizziness, headache, urinary frequency, and gaseous distention were the symptoms noted during the verapamil period.

No laboratory abnormalities occurred that were considered to be drug related.

Discussion

A striking early improvement (usually on the first day) was noted by most patients on verapamil. In addition to a sharp curtailment in the number of anginal attacks and a reduced need for nitroglycerin, many patients noted a sense of well being with a desire and ability to be more active. Because of this, the numerical data do not fully show the clinical effects of the drug. Many patients found they were able to perform work (such as shoveling snow, mowing lawns, etc.) which they were unable to do during the baseline or placebo period. This added work may have maintained the attack rate. A variety of other drugs previously given to these patients were continued during the study period without any unusual effects. These include: anticoagulants, hypoglycemic agents, thiazide diurectics, antidepressants and tranquilizers.

A further indication of the measure of benefit derived from verapamil can be obtained from the fact that, despite the inconvenience of repeated laboratory and clinical evaluation necessary during the experimental study, all patients wished to continue with verapamil.

Results

The raw data from this study consisted of three measures. Each patient reported the number of exertional angina attacks, the number of nonexertional angina attacks, and nitroglycerine tablets taken between visits. Patients were examined at 14-day intervals. Two observations were made at baseline while the patients were known by the investigator to be on placebo. Thereafter, each patient was placed in a double-blind fashion on either verapamil or placebo for five visits then crossed over to the alternate drug for another five visits.

Each measure was analyzed three ways. Verapamil was considered effective if each number of episodes of angina the patient experienced while on verapamil was less or equal to the smallest number recorded while the patient was on placebo, or if the number recorded while the patient was on placebo was greater than or equal to the greatest number recorded while the patient was on verapamil. This method of analysis tends to downgrade the effect of verapamil by failing to consider

TABLE 1

SignTest Significance Level	0.006	7.17	0.035

marginal cases. The number who appeared better on verapamil were subjected to a sign test. The results are displayed in Table 1, indicating significant improvement under verapamil for exertional attacks and for the number of nitroglycerine tablets.

For the second method, baseline averages were calculated for each patient on each measure. Each recorded value was then converted to percentages of baseline. Mean percentages for verapamil and for placebo were then subjected to a paired t test. The results indicate significant improvement of exertional attacks and for nitroglycerine consumption.

Finally, the differences between the observed value and the baseline were compared by the mean sign test (Table 3).

By all three methods of analysis, verapamil decreased both the number of exertional attacks of angina pectoris and the number of nitroglycerine tablets taken.

Conclusion

Verapamil at a dose of 80 mg q.i.d. (320 mg per day) effectively decreases the frequency of angina pectoris due to coronary artery disease. Drug side effects included constipation and dysuria and were mild in severity.

Acknowledgment

The verapamil and an identical appearing placebo were made available by Chas. Pfizer & Co., Inc., & Knoll Pharmaceutical. I would like to thank Dr. Kenneth Ahola, Angeline Johnson, R.N., Antoinette Mestnick, R.N., and Darla Willmarth, L.P.N. for their assistance in the study.

Laboratory Letter

Creatinine and Creatine Phosphokinase (CPK)

Why creatinine?

Because it's the best single serum test for evaluating renal function. And because, when measured with urine creatinine, it can be used to calculate creatinine clearance—the most commonly used test to approximate glomerular filtration rate.

The Council on the Kidney of the American Heart Association has established these criteria for evaluating severity of established renal disease:[1]

Class A
- Primary: Glomerular filtration rate normal
- Secondary: Serum creatinine normal

Class B
- Primary: Glomerular filtration rate reduced more than 50%
- Secondary: Serum creatinine normal to 2.4 mg/100 ml

Class C
- Primary: Glomerular filtration rate 10% to 50% of predicted normal
- Secondary: Serum creatinine, 2.5 to 4.9 mg./100 ml.

Class D
- Primary: Glomerular filtration rate 10% to 20% of predicted normal
- Secondary: Serum creatinine, 5.0 to 7.9 mg/100 ml

Class E
- Primary: Glomerular filtration rate less 10% of predicted normal
- Secondary: Serum creatinine, 8 to 12 mg/100 ml

Class F
- Primary: Glomerular filtration rate less than 5% of predicted normal
- Secondary: Serum creatinine greater than 12 mg/100 ml

BUN/Creatinine Ratio

Is there anything else you ought to know about creatinine and creatinine clearance?

There must be many things, but two spring immediately to mind: (1) If pre-renal azotemia exists (from reduced renal plasma flow due to dehydration, congestive failure, shock, or circulatory slowing in desperately sick patients), you ought to anticipate a discrepancy between BUN and creatinine. In most of these instances, the ratio of BUN to creatinine will exceed 10:1.[2] If true renal insufficiency exists, however, the ratio is usually less than 10:1. To summarize and elaborate:

(A) If BUN/creatinine ratio is more than 10:1, following more likely:
pre-renal azotemia from dehydration, shock, heart failure
excess protein intake when renal function is depressed
blood in bowel
tissue breakdown in starvation, fever, burns, steroid therapy, or any wasting pre-terminal state
urinary tract infection
occasionally hemorrhagic or embolic glomerulonephritis
ureterocolostomy

(B) If BUN/creatinine ratio is less than 10:1, following more likely:
renal insufficiency
low protein intake
repeated dialysis for chronic renal disease
severe diarrhea or vomiting in chronic renal disease
severe hepatic insufficiency with renal insufficiency

(2) The creatinine clearance depends on age.[3] As you age, you clear less creatinine through your kidneys. For this reason, creatinine clearance declines as you grow older.

Normal Range for Creatinine Clearance

Age	Men	Women
20-29	100-135	85-115
30-39	90-120	75-100
40-49	80-110	70- 90
50-59	75-100	65- 85
60-69	65- 90	55- 75
70-79	60- 80	50- 65
80-89	45- 60	35- 50
90-99	30- 45	25- 40

Now, CPK

Which brings us to creatine phosphokinase (CPK).

Why CPK at all? Aren't there enough enzyme tests already? Why complicate matters with yet another?

Because CPK isn't like the others.

You see, there isn't any CPK in the liver. It's in skeletal, smooth, and heart muscle. And in brain tissue. But not in the liver. Think about that just a moment. Alkaline phosphatase, LDH SGOT, and SGPT abound in the liver. But not CPK. So? So, if CPK is strikingly up, you can bet muscle damage—not liver damage—is the source. If on the other hand, the other enzymes are out of sight and CPK is normal, you can surmise the problem's inside Glisson's capsule.

Two Rumors, Three Bicycles

Recently I got the chance to chase down two rumors with three bicycles. The first rumor was that strenuous exercise elevated CPK. The second was that CPK broke down quickly after being placed in a serum vial. So, when three of our employees went on an 80 mile bicycle ride, we drew their blood when they returned and checked these same serum samples again after the sample sat on the counter at room temperature for three and five days. This is what was found:

Value After Three and Five Days

	Initial Value	at room temperature		Normal upper
Bicyclists	after ride	day three	day five	limits
Woman	65	70	65	50
Man	115	115	120	75
Man	160	160	155	75

As you can see, strenuous exercise elevated the CPK so it exceeded the upper limit by 15 to 85 units—confirming the first rumor. But CPK levels did not decline —even after sitting for five days—spiking the second rumor.

Relative CPK Magnitudes

Because muscle is so rich in CPK (The ratio of CPK activity in skeletal to heart muscle is 10:1[4]), almost anytime you cut, cauterize, bruise, stretch, manipulate or otherwise tamper with muscle, CPK will rise. Yes, that's true, say proponents of CPK use, ". . . but not significantly." So the question becomes: "What do you consider significant?" To try to answer that I've done some moseying around the literature with these results:

	Average increase of upper limit
Muscular dystrophy[5]	
Duchenne type	100 fold increase
Limb-Girdle	8 fold increase
Fascioscapulohumeral	3 fold increase
Myocardial Infarction[5-7]	10 to 40 fold increase
Major Surgery,[8] postoperative levels	
thoracic	8 fold increase
open heart	12 fold increase
intra-abdominal	9 fold increase
Urological Procedures with cutting of bladder muscle[9]	3 fold increase
IM Injection[10]	2-6 fold increase

Brain Damage and CPK

One of the odd things about CPK is that it consistently goes up in brain damage, yet on electrophoresis of CPK, the source of this elevated CPK appears to be muscle—not brain tissue.

From Australia comes word that CPK levels were elevated in all of 22 cases of encephalitis and meningitis.[11] And American psychiatrists report high CPKs in 24 of 37 acute psychotic patients.[12] But perhaps the best study comes from the British.[13] They report the following:

	Number of Patients	Number with Abnormal CPK	Number with Levels Greater than 10 normal	Number with Levels Greater than 20 times normal
Head Injuries	14	14	13	7
Strokes	21	15	2	0
Meningitis	7	3	0	1

To my knowledge, CPK is the only enzyme in the peripheral blood that goes up when a stroke occurs. This property could make CPK a valuable test in assessing brain damage or in differentiating between cerebrovascular insufficiency versus cerebrovascular necrosis.

Alcohol Ingestion and CPK

Yet another dilemma occurs in alcoholics. Although many alcoholics have liver damage, almost as many have muscle injury. In St. Louis, Perkoff, et al. observed a five-fold increase in CPK of 21 alcoholics compared to normal subjects.[14] And in Philadelphia, Lafair and Myerson reported these observations:[15]

	Number of Patients	Number with Abnormal CPK	Mean Peak Value of CPK
Chronic Alcoholics with no recent drinking	11	0	Normal
Chronic Alcoholics with acute muscle pain	6	6	4.4 times upper limit of normal
Chronic Alcoholics with delerium tremens	24	21	8.6 times upper limit of normal
Chronic Alcoholics admitted with acute intoxication	20	15	5.4 times upper limit of normal

Myocardial Infarction and CPK

Just a word about interpreting CPK in myocardial infarction. CPK acts essentially like a sensitive short-lived SGOT. CPK rises sooner than SGOT (three to six hours vs. six to 12 hours), peaks higher (40 times upper limit vs 12 times upper limit), and drops to normal quicker (perhaps a few hours). Here is some information indicating how CPK contrasts with SGOT and LDH.[16]

Post-Myocardial Infarction	Percent with Elevated Values		
	CPK	SGOT	LDH
1 day	100%	95%	87%
4 days	88%	96%	96%
7 days	50%	58%	70%
10 days	30%	50%	40%
14 days	0%	20%	40%

Hypothyroidism and CPK

Then there is the tricky business of elevated CPK levels in hypothyroidism (and of decreased CPKs in hyperthyroidism). No one knows why for sure, but hypothyroid patients run CPKs about eight times the normal mean, with levels reaching two to five times the upper limit.[17,18] Furthermore, the degree of CPK abnormality parallels the degree of hyperthyroidism.

A Final Note

I don't want to leave you with the impression I devote all of my energy digging in dark corners of the literature. Not so. I occasionally corroborate what I read, in light of local knowledge.

To check the validity of the BUN/Creatinine ration in distinguishing between pre-renal azotemia and true renal damage, I asked two colleagues, Doctors Patrick Ward and Desmond Burke, pathologists at Mt. Sinai in Minneapolis, to gather records on 25 patients with congestive failure—far and away the most common cause of pre-renal azotemia. I did so because the Mt. Sinai SMA—12/60 simultaneously measures BUN and creatinine on all patients.

In all of the congestive failure patients, the BUN/Creatinine ratio was greater than 10:1. In 22 of 25 patients, the ratio exceeded 11:1. The mean ratio was between 18:1 and 19:1.

And, with the help of Doctor David Kvistberg, biochemist at Lufkin Medical Laboratories, I checked out the magnitude of CPK elevations in chronic alcoholics and hypothyroidism. In 14 alcoholics admitted to an alcoholic treatment center, he found three with high CPKs. None of these CPKs surpassed 1.3 times the upper limit of normal. Among 13 patients with low T-4s (Murphy-Pattee), six had elevated CPKs. The highest value, 350 units or about five times the upper limit of normal for women, occurred in a patient with a T-4 of 0.1.

Richard L. Reece, M.D.

In gram-negative sepsis*...

*Due to susceptible organisms

Schering

The antibiotic of first resort...

In suspected or documented gram-negative sepsis, GARAMYCIN Injectable may be considered as initial therapy.

- Effectiveness against the nosocomial problem pathogens of the 1970's
- Proven clinical effectiveness
- Risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended
- Effective against pathogens resistant to many commonly used antibiotics
- Versatility and convenience of administration

Garamycin®

brand of gentamicin sulfate injection

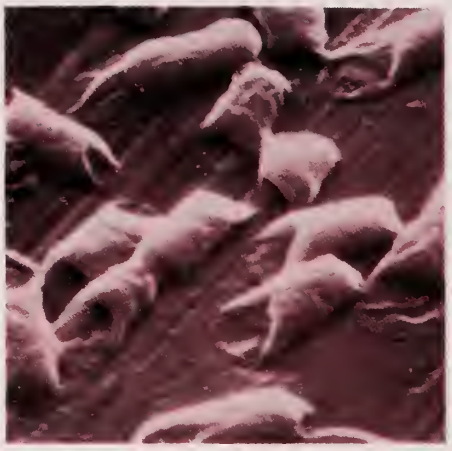
injectable

I.M./I.V.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

See Clinical Considerations section which follows...

The antibiotic to start with...



*In suspected or documented gram-negative sepsis due to susceptible organisms, GARAMYCIN Injectable may be considered as initial therapy. Th decision to continue therapy with this drug should be based on the results o susceptibility tests, the severity of the infection, and the important concept contained in the Warning Box below.

An indispensable spectrum for today[1-3]

GARAMYCIN Injectable offers a high probability of effectiveness against virtually all of the gram-negative pathogens which are a growing cause of clinical concern. GARAMYCIN Injectable has also demonstrated striking activity against *Proteus* species, both indole-positive and indole-negative.[2]

Proven clinical efficacy[1,4-13]

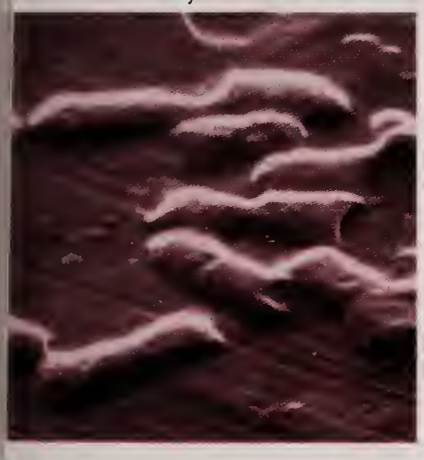
GARAMYCIN Injectable may be lifesaving in septicemia... may give a dramatic response in wounds and burns complicated by sepsis. GARAMYCIN Injectable has also demonstrated outstanding results in serious gram-negative infections other than sepsis, such as serious respiratory infections and selected urinary tract infections. To date, GARAMYCIN Injectable has been the subject of more than 1,500 published papers and 12 international symposia.

Note: The photomicrographs of gram-negative organisms reproduced here were obtained by a relatively new process employing a scanning beam electron microscope. The pathogens represented are *Klebsiella pneumoniae*, *Escherichia coli*, and *Proteus mirabilis*. The colors shown here are an artist's representation. The magnification is 10,000X.

WARNING: Patients treated witl GARAMYCIN Injectable should be under close clinical observation because the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, pa and those with pre-existing renal dam e, treated with GARAMYCIN Injectab usually for longer periods or with gh doses than recommended.

GARAMYCIN Injectable is potentially



Schering

The antibiotic to stay with*

A high degree of sensitivity maintained[14-16]

Bacterial resistance to GARAMYCIN Injectable has not been a problem to date. In the laboratory, resistance has been demonstrated to develop slowly in stepwise fashion. No one-step mutations to high resistance have been reported. One investigator noted: "In the experience so far with [gentamicin], which is 7 or 8 years, in centers where it's been restricted to parenteral use, resistance has not appreciably changed."[14] Another authority "...found very little emergence of resistance" during eight years of use.[15]

In a survey of published studies on resistance to gentamicin, Weinstein and co-workers[16] report little change in bacterial sensitivity since 1963 in the percentage of sensitive strains. *In vitro* sensitivity was determined in all cases by the tube-dilution method.

Relatively low incidence of adverse reactions[3,14,17]

As with certain other aminoglycoside antibiotics, ototoxicity (primarily vestibular with gentamicin) and potential nephrotoxicity are risks of therapy.

Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy.

In contrast to kanamycin, neomycin, and streptomycin, which primarily cause deafness or difficulties in the auditory end organs of the eighth nerve, gentamicin primarily causes labyrinthian dysfunction.[14] This dysfunction, manifested by dizziness (not deafness) has, in most cases, been transitory.

As to nephrotoxicity, according to Finland,[3] "as in the case of kanamycin, the nephrotoxicity was found to be largely 'potential,' and very little if any has been encountered except with obviously excessive doses or in patients with already damaged kidneys."

Garamycin®
brand of gentamicin sulfate injection

injectable
I.M./I.V.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

ephrotoxic, and this should be kept in ind when it is used in patients with re-existing renal impairment.

Monitoring of renal and eighth nerve nction is recommended during therapy f patients with known impairment of nal function. This testing is also commended in patients with normal nal function at onset of therapy who evelop evidence of nitrogen retention ncreasing BUN, NPN, creatinine or liguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

Usage in Pregnancy: Safety for use in pregnancy has not been established.

See Clinical Considerations section which follows...

When preculture signs point to gram-negative sepsis...

Garamycin® Injectable
brand of gentamicin sulfate U.S.P., injection 40 mg./cc.
Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin
For Parenteral Administration

WARNING: Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause toxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

INDICATIONS GARAMYCIN Injectable is indicated, with due regard for relative toxicity of antibiotics, in the treatment of serious infections caused by susceptible strains of the following microorganisms:

Pseudomonas aeruginosa, Proteus species (indole-positive and indole-negative), **Escherichia coli** and **Klebsiella-Enterobacter-Serratia** species.

Clinical studies have shown GARAMYCIN Injectable to be effective in septicemia and serious infections of the central nervous system (meningitis), urinary tract, respiratory tract, gastrointestinal tract, skin and soft tissue (including burns).

Bacteriologic tests to determine the causative organisms and their susceptibility to gentamicin should be performed.

Bacterial resistance to gentamicin develops slowly in stepwise fashion; there have been no one-step mutations to high resistance.

In suspected or documented gram-negative sepsis, GARAMYCIN may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important additional concepts contained in the "Warning Box." In the neonate with suspected sepsis or staphylococcal pneumonia, a penicillin type drug is usually indicated as concomitant antimicrobial therapy.

GARAMYCIN Injectable has been shown to be effective in serious staphylococcal infections. It may be considered in those infections when penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

CONTRAINDICATIONS A history of hypersensitivity to gentamicin is a contraindication to its use.

WARNINGS (See "Warning Box.")

PRECAUTIONS Neuromuscular blockade and respiratory paralysis have been reported in the cat receiving high doses (40 mg./kg.) of gentamicin. The possibility of these phenomena occurring in man should be considered if gentamicin is administered to patients receiving neuromuscular blocking agents such as succinylcholine and tubocurarine.

Treatment with gentamicin may result in overgrowth of nonsusceptible organisms. If this occurs, appropriate therapy is indicated.

ADVERSE REACTIONS

Nephrotoxicity: Adverse renal effects, as demonstrated by rising BUN, NPN, serum creatinine and oliguria, have been reported. They occur more frequently in patients with a history of renal impairment treated with larger than recommended dosage.

Neurotoxicity: Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss.

Numbness, skin tingling, muscle twitching, and convulsions have also been reported.

Note: The risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

Other reported adverse reactions, possibly related to gentamicin, include increased serum transaminase (SGOT, SGPT), increased serum bilirubin, transient hepatomegaly, decreased serum calcium; splenomegaly, anemia, increased and decreased reticulocyte counts, granulocytopenia, thrombocytopenia, purpura; fever, rash, itching, urticaria, generalized burning, joint pain, laryngeal edema; nausea, vomiting, headache, increased salivation, lethargy and decreased appetite, weight loss, pulmonary fibrosis, hypotension and hypertension.

DOSAGE AND ADMINISTRATION GARAMYCIN Injectable may be given intramuscularly or intravenously.

For Intramuscular Administration:

PATIENTS WITH NORMAL RENAL FUNCTION*

Adults: The recommended dosage for GARAMYCIN Injectable for patients with serious infections and normal renal function is 3 mg./kg./day, administered in three equal doses every 8 hours.

For patients weighing over 60 kg. (132 lb.), the usual dosage is 80 mg. (2 cc.) three times daily. For patients weighing 60 kg. (132 lb.) or less, the usual dose is 60 mg. (1.5 cc.) three times daily.

In patients with life-threatening infections, dosages up to 5 mg./kg./day may be administered in three or four equal doses. This dosage should be reduced to 3 mg./kg./day as soon as clinically indicated.

*In children and infants, the newborn, and patients with impaired renal function, dosage must be adjusted in accordance with instructions set forth in the Package Insert.

For Intravenous Administration:

The intravenous administration of GARAMYCIN Injectable is recommended in those circumstances when the intramuscular route is not feasible (e.g., patients in shock, with hematologic disorders, with severe burns or with reduced muscle mass).

For intravenous administration, in adults, a single dose of GARAMYCIN Injectable may be diluted in 100 or 200 cc. of sterile normal saline or a sterile solution of dextrose 5% in water; in infants and children, the volume of diluent should be less. The concentration of gentamicin in solution, in both instances should normally not exceed 1 mg./cc. (0.1%). The solution is infused over a period of 1 to 2 hours.

The recommended dose for intravenous administration is identical to that recommended for intramuscular use.

GARAMYCIN Injectable should not be physically pre-mixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

HOW SUPPLIED GARAMYCIN Injectable, 40 mg. per cc., 2 cc. multiple dose vials for parenteral administration.

Also available, GARAMYCIN Pediatric Injectable, 10 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Review—

Psychiatric Disabilities of the Vietnam Veteran

Review and Implications for Treatment

GAYLE K. LUMRY, Ph.D., CHERRY B. CEDARLEAF, M.D.
M. SUZANNE WRIGHT, Ph.D., AND GORDON A. BRAATZ, Ph.D.

APPROXIMATELY ONE-FOURTH of all hospitalized Vietnam veterans are treated for a primary psychiatric disability. Psychological factors also enter into physical illnesses and the magnitude of this problem is such that more information is needed in order to formulate treatment objectives.

Method

The clinical records of 458 psychiatric and 48 medical patients were reviewed. The psychiatric sample included patients under 26 years of age, admitted to the psychiatric service of the Minneapolis Veterans Hospital from 1963 to 1969, and who were otherwise free of serious medical problems. The 48 medical controls, who were also under 26 years of age, represented a wide variety of medical disabilities and were seen at the Minneapolis Veterans Hospital from 1963 to 1969. The only difference between the two groups in respect to military experience was that about one-third of the psychiatric patients were still on active duty at the time of the admission and none of the medical patients were on active duty.

Results

Demographic Characteristics

One-fourth of the psychiatric sample did not complete high school. Most of the veterans had little or no pre-service work or technical training. Of the psychiatric patients, 60% were single and the married veterans almost uniformly reported marital problems sufficient to require counselling. Also 40% of the psychiatric patients were from homes which were broken by divorce, separation or desertion, and in 48% of the families there was a severe degree of psychopathology including alcoholism, child-abuse, and psychotic episodes in one or both parents.

Diagnoses

The clinical diagnoses are shown in Table 1. To a far greater extent than is true of older patients there were ambiguities in diagnoses since physicians found it necessary to employ a long series of modifying phrases even to approximate a gross description of a patient. As noted by Siegel,[2] at one end of the spectrum are the patients with a character disorder who are relatively well integrated and who relate well socially. At the other end of the spectrum are severely withdrawn, psychotic (usually schizophrenic) individuals who have great difficulty with interpersonal relationships and socialization. Between these two groups are the patients who vary in ability to relate to others and in the degree of withdrawal.

Adjustment Deficiencies

A sample of 200 patients was evaluated for deficiencies in six major life areas. As can be seen from Table 2, the marked vocational and interpersonal maladjustment (especially failure in marital adjustment) is striking. The magnitude of these difficulties is even clearer when it is recognized that three-fourths of the psychiatric group had

TABLE 1

difficulties in at least three of the six areas of life adjustment.

TABLE 2
Percentage of Patients Having Deficiencies in Six Life Adjustment Areas

Life Adjustment Areas	Percent Deficient
Education: School attainment below intellectual potential. Lacks vocational training or employable skills	52%
Vocation: Not well established in a vocation	84%
Socialization: Does not have satisfying interests or hobbies	55%
Sexual Adjustment: Expresses conflict about sex	58%
Interpersonal Adjustment: Unable to maintain satisfying interpersonal relationships	76%
Family Relationships: Still very dependent upon family, considerable conflict with family	57%

Acting Out Potential

Another important consideration in evaluation of treatment needs is the assessment of behavior which might indicate "acting out potential." These proclivities directed outwardly in anti-social acts and assaultive behavior or self-inflicted injuries, drug addiction or alcohol abuse, must be considered in treatment planning.

TABLE 3
"Acting-Out Potential" of Young Veteran Patients (N=458)

	Active Service N-157	Other Veterans N-301	Vietnam Veterans N-85	Total # N-458
Alcohol Problems	42.0%	40.0%	51.7%	40.8%
Drugs	25.4	11.8	16.4	16.5
Suicidal or Assaultive	63.6	36.8	43.5	54.1
Suicidal Acts	35.6	15.9	21.1	26.6
Disciplinary Problems, Civilian or Military	24.1	26.2	27.0	25.7

Comparison of the MMPI Profiles

The mean MMPI profile for the medical school sample reflects considerably less distress than the psychiatric sample. This is even more interesting in view of the fact that two-thirds of the medical control group had served in Vietnam while only 18% of the psychiatric group had served there. The mean profiles of the psychiatrically disabled veterans who have had active duty in Vietnam could not be reliably discriminated from those who had served elsewhere, or from those who were in active service at the time of the psychiatric hospitalization.

TABLE 4
Mean MMPI T Scores for the Vietnam Era Patient Samples

	Psychiatric Patients	Medical Patients
Lie Scale (L)	48.4	47.9
Validity Scale (F)	72.8	60.4
Correction Scale (K)	49.3	54.2
Hypochondriasis (Hs)	65.6	62.3
Depression (D)	76.5	62.3
Hysteria (Hy)	68.7	62.7
Psychopathic Deviate (Pd)	76.3	64.5
Masculinity-Femininity (Mf)	63.8	56.3
Paranoia (Pa)	70.6	56.4
Psychasthenia (Pt)	77.7	63.3
Schizophrenia (Sc)	82.7	67.8
Hypomania (Ma)	67.8	62.5
Social Introversion (Si)	59.4	51.9

Conclusions

This study suggests that the psychiatric disabilities of Vietnam veterans follow a continuous pattern like those found in civilian practice. In addition, almost all the psychiatrically disabled veterans have had education, vocational or social problems of a serious nature prior to entering active duty. Sexual adjustment has not been adequate and general, interpersonal adjustment and family relationships can be characterized as either unsatisfactory or insufficient. From our data it would appear that active military duty may exacerbate symptoms, but is not a sufficient cause in itself to explain their disabilities and psychiatric illnesses. Moreover duty in Vietnam in itself cannot be blamed for the psychiatric disabilities of these individuals. Indeed, most of our psychiatrically disabled veterans have not served in the combat area.

Recommendation for Treatment

A full range of psychiatric facilities could effectively meet the needs of these young patients. A patient's involvement in such a multifaceted treatment program should begin with a thorough evaluation in an in-patient service for a period of time sufficient for the formulation of an effective, long-term program. Major areas of personality adjustment must be approached, especially those areas which were deficient prior to the veteran entering the Armed Forces. Most of our patients could be treated on some form of psychiatric service which does not require full-time in-patient care. Married patients and single patients with close parental family ties might find a modification of the day hospital most effective. The Minneapolis Vet-

rans Hospital has already achieved considerable uccess with these individuals. Some individuals /ho do not fit this category may require some orm of community living arrangement. Many pa-ients need to take steps in order to achieve inde-endence from their parents and to acquire suffi-ient integration to maintain themselves without upport in the greater society. Perhaps such a pro-ram could involve an apartment complex housing 6-24 residents which could provide the varying legrees of independence and yet, enhance "in a rotective setting" social integration. Certainly, educational-vocational programs could be pursued luring the day with evening activities directed owards socialization and improved interpersonal elationships. Group therapy, discussion of topics f general interest and concern, social activities nd recreation could be included. In addition to a rofessional staff, hopefully, volunteers would also be available to provide the necessary peer relationships as well as some of the adult leadership required.

Summary

It is evident that varied programs are needed for Vietnam veterans and these must be different from the usual medical models we have used in the past. Most of our patients have not developed stability and maturity before entering the Armed Forces and it is essential for them to have assistance in developing these characteristics if they are to cope with society and avoid recurrent hospitalization. Immeasurable benefits are to be gained by helping these patients to achieve greater productivity and a happier, more comfortable relationship in our society. To create and implement such a program requires a more flexible approach than orthodox, in-patient psychiatric care.

Cerebral Concussion Syndrome in Children

Schnitker described a syndrome of concussion in 11 children who suffered minor head injury. The clinical picture followed a blow to the frontal or temporal skull, after which there was a lucid interval with crying, vomiting, and mild shock. These symptoms were followed by a period of traumatic stupor that closely resembled the classic syndrome of extradural hematoma in the adult.

According to Schnitker, the cause was probably a mild, localized, cerebral edema extending to the region of the diencephalon. The condition should be differentiated from that of cerebral contusion in which the injury is more severe and there is prolonged unconsciousness. Recovery was complete in 24 hours.

Psychiatry

The Schizophrenic

The Pill or Not the Pill—Fluphenazine Enanthate an Answer

WILLIAM W. BRAUER, M.D.

THE AUTISTIC meandering of a schizophrenic reverie leaves little room for logic. The daily repetitious question of "Should I take my pill?" is a logical one, for without medications the schizophrenic may have a 75 percent chance of rehospitalization.[1] Taking a pill involves timing, trust, memory, and consistency. Unfortunately, schizophrenic disorganization disrupts these traits.

Until recently physicians had to rely on either the patient, the relatives, or the nurse to ensure that medication was taken properly by the schizophrenic patient.

Introduction

Fluphenazine hydrochloride[2,3] (Prolixin) is known to be an effective antipsychotic drug. It is fat-soluble and released slowly from fatty tissue. Esterification with various acid esters, particularly Enanthic acid, further reduces the rate of release of Fluphenazine in the body. Dissolving this ester in sesame oil constitutes the injectable Fluphenazine Enanthate.

This depot Fluphenazine product is released from the buttock injection site and the sustained therapeutic effect may continue for two weeks after the injection. Side effects are similar to those of the oral Fluphenazine and caution is necessary, as once the drug is injected it cannot be retrieved. Used properly, however, Fluphenazine Enanthate affords numerous therapeutic advantages.

Indications

The Acutely Psychotic

An acutely psychotic and delusional schizophrenic is often too disturbed to accept pills. He thinks that medication destroys his grandiose talents or that it may indicate a poison plot.

A 20-year-old disturbed schizophrenic was admitted to the hospital forcefully after several nights of wandering aimlessly throughout the city. Medication was refused because it would "disrupt my religious powers." After he received ½ cc (12½ mg) of Fluphenazine Enanthate, his threats to leave the hospital were discussed for the next few days. Rather rapidly his philosophical and religious musings decreased and he cooperated in accepting treatment. Five days after the initial injection, a repeat injection was given and benztropine mesylate (Cogentin), one mg tablet twice a day, was added to the therapy. Within several weeks this young man was discharged from the hospital and has remained on a weekly dosage of 12½ mg of Fluphenazine Enanthate. He has worked steadily the past six months and faithfully continues his medication.

Merry-go-round Syndrome

Many schizophrenics demonstrate "the merry-go-round syndrome;"[4] repetitive hospitalizations precipitated by interruption of phenothiazine therapy by the patient. His improvement on phenothiazine therapy allows a false feeling of recovery and, either because of this or other rationalizations, he discontinues the medication.

A 26-year-old man had a six-year history of schizophrenia. Following an acute psychotic episode in college, treatment has included electroshock therapy, medications, and approximately 10 re-hospitalizations. During my two-year care of this young man, he has been re-hospitalized on three occasions, each time within two to four weeks of his unilaterally discontinuing his phenothiazines. Despite periodic review of these failures, he gained no insight. On his last hospitalization Fluphenazine Enanthate therapy was begun: weekly injections of ½ cc (12½ mg). He has worked now a total of four months, a feat impossible in the preceding six years. He has remained now with his parents, although on five previous occasions in the past six years he had eloped and ended up being hospitalized in such distance places as California, New York, and Canada. Even now he continues to lack insight and may admit that he has stopped chlorpromazine (Thorazine) or other additional medications he receives. On occasion he has marked dystonia and extrapyramidal side effects; at those times he admits discontinuing his Cogentin. Recently, however, he has taken the Cogentin faithfully and appears to be learning the necessity for medication.

Periodic Aggression

The schizophrenic with periodic aggression represents a dangerous threat to the community. A homicidal, paranoid patient who has recovered from a psychosis through pharmacotherapy will usually stay well as long as he remains on medica-

Reprint request address to: Dr. W. W. Brauer, 527 Medical Arts Building, Minneapolis, Minnesota 55402.

tion. The psychiatrist in this situation has a duty to insure that this potentially aggressive individual is on medication and thus well under control.

A 19-year-old man had been treated with a five-month hospitalization one year prior to my care. In the past year and one-half, he has had aggressive outbursts at home in which he attacked his father or mother. At various times they received trauma sufficient for them to be hospitalized. When medication including Thorazine and oral Fluphenazine was insufficient to prevent his outbursts, he began Fluphenazine Enanthate weekly injections of ½ cc (12½ mg). In the past seven months he has remained at home, rather isolated from peers and the community, but has had no aggressive nor violent outbursts. He is cooperative with his parents and also with his weekly hospital visits for his medication. He speaks only rarely of his delusional system which in the past consisted of thoughts that people were looking at him, talking about him, and thinking him homosexual. He no longer mentions the delusions that other people are accusing him of molesting young women.

Discussion

The three problem patients above are responding well to treatment. The main feature of their treatment includes Fluphenazine Enanthate, although simultaneously all received mega-vitamin treatment as advocated by Hoffer.[5] Other adjuncts included daily Cogentin to control the extrapyramidal effects and occasional simultaneous use of oral phenothiazines. Although no proof exists that Fluphenazine Enanthate is the sole agent responsible for their improvement, care of these patients would have been markedly handicapped or would have failed without the use of intramuscular, long-acting, antipsychotic medication.

Advantage of Injectable

Cole[3] points out two possible advantages of the injectable over the oral form of Fluphenazine. One is that the drug is absorbed into the blood stream and goes through the lungs *to the brain before passing through the liver*. It may well be that chronic schizophrenic patients with long histories of exposure to phenothiazines have developed hepatic enzymes. These enzymes are highly efficient at metabolizing and deactivating orally administered phenothiazine medication. The use of the long-acting injectable form may provide an effective level of drug in the brain which may have been achievable only by extraordinarily high oral doses of similar medications. The second advantage is that the long-acting injectable Fluphenazine is more effective because it provides to all patients a *higher level of drug in the central nervous system* than would be achieved by much higher doses of oral Fluphenazine.

Many clinicians report using Fluphenazine Enanthate at fortnightly intervals (every two weeks) and may give one cc (25 mg) or higher doses per injection. Yet many patients complain bitterly of extrapyramidal side-effects and listlessness the second through the fourth day of post-injection therapy. To decrease this reaction, weekly shots at a decreased dosage as illustrated in the examples decrease the side-effects of the medication; however, the more frequent injections decrease the advantage of the long-lasting effect of the medication. Extrapyramidal effects are fairly well controlled through the use of such drugs as Cogentin. Studies indicate that the long-acting extrapyramidal side-effects are no different from those of routine anti-psychotic drugs although the onset may be different and the dystonic reactions a little more bizarre.[3] Hematologic and liver disturbances are rare, but periodic blood tests are advisable.

Advantage to Side Effects

An interesting advantage acrues from the side-effects of the medication. Extrapyramidal effects are disturbing to the patient and point out the necessity vividly described in the patient with the merry-go-round syndrome for medication to counteract the muscular discomfort. From a behavioral modification standpoint, patients on depot Fluphenazine eventually learn that medication is important. While they may neglect taking phenothiazines because "it doesn't do me any good," they will happily and conscientiously take the anti-parkinsonism agents to relieve physical discomfort. This patterned performance is helpful in learning medication schedules and proves useful if at a future time medication is shifted to oral Fluphenazine or other phenothiazines. "The pill or not the pill" becomes a forgotten issue in many of these improved schizophrenic patients.

Summary

The long-acting injectable form of Fluphenazine has unique value in the treatment of schizophrenia. It is indicated for use in patients who refuse oral medications, patients with exacerbations of illness due to discontinuation of medication, and individuals with severe paranoid homicidal tendencies who are potentially a threat to the community. Fluphenazine Enanthate appears more active in causing extrapyramidal and lethargic effects than has been reported elsewhere. Titra-

tion of medication and use of antiparkinsonism drugs may be necessary. Fluphenazine Enanthate is the drug of choice in some schizophrenic illnesses and merits wider popular use by the medical profession.

In Memoriam

God's finger touched him, and he slept.—Tennyson

OMER E. SNYKER, M.D.

Dr. Omer E. Snyker, 66, Ely physician, died September 2. Born in St. Paul, Dr. Snyker took pre-medical courses at the University of Minnesota in the early 1920s and later studied part-time at Loyola University Medical School, getting his degree there in 1934. Four years later he chose Ely to set up his practice. In 1945 he converted the brick school into Ely's first hospital.

He was a member of the Range Medical Society and the American Medical Association and was an Associate Member of the Minnesota State Medical Association.

Dr. Snyker is survived by his sons, Donald, Gary and Kenneth, and one daughter, Mrs. William Mackie.

CHARLES W. FROATS, M.D.

Dr. Charles W. Froats, 72, a former chief of the medical staff of St. Luke's in St. Paul died August 30. His medical education was obtained at Northwestern University Medical School in Chicago.

He was a member of the Ramsey County Medical Society and the American Medical Association, a Fellow of the American College of Surgeons and the Central Association of Obstetricians and Gynecologists, a charter member of the Minnesota Society of Obstetrics and Gynecology, and a Life Member of the Minnesota State Medical Association.

Dr. Froats is survived by his wife, Doris, a daughter, Mrs. Thom Jordan and sons David J. and Charles W., Jr.

IVAN C, DIMMICK, JR,, M.D.

Dr. Ivan C. Dimmick, the senior staff physician at the Brainerd State Hospital, died July 25. He was 62. Dr. Dimmick came to the State Hospital in March of 1970 after retiring from military service with the rank of colonel.

He was a member of the Upper Mississippi Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Dimmick is survived by his wife, Marion.

EDWARD N. COOK, M.D.

Dr. Edward N. Cook, 66, Mayo Clinic urologist emeritus, died July 26. He was a member of the department of urology at the Mayo Clinic and professor of urology in the Mayo Graduate School of Medicine from 1936 until his retirement in 1970.

Born in St. Paul, Dr. Cook obtained his doctor of medicine degree from the University of Minnesota. He went to Rochester in 1930 as a fellow in surgery in the Mayo Graduate School.

Dr. Cook was certified as a specialist in urology by the American Board of Urology and was a member of the International Society of Surgery, the American Medical Association, the American Urological Association, the Southern Minnesota Medical Association, the North Central Section of the American Urological Association, the Zumbro Valley Medical Society, an honorary member of the Mexican Urologic Society and of the South Central Section of the American Urological Association. He was a Residency Member of the Minnesota State Medical Association.

Dr. Cook is survived by his wife, Jean, a son Edward and two daughters, Mrs. Carroll Berndt and Mrs. Bruce Nelson.

FREDOLPH H. MAGNEY, M.D.

Dr. Fredolph H. Magney, 86, Duluth physician, died September 6. Born in Ellsworth, Wisconsin, Dr. Magney graduated from the University of Minnesota Medical School in 1915 and established his practice in Duluth the following year.

He was a member of the American Medical Association, St. Louis County Medical Society and the state board of medical examiners. He was a fellow of the American College of Surgeons and had been chief of staff of all three Duluth hospitals. In 1955 he was given the Distinguished Service Award by the Minnesota State Medical Association and was a 50 Club and Life Member of this organization. A member of the St. Louis County Tuberculosis and Health Association, Dr. Magney was instrumental in that organization's acquisition of the first mobile tuberculosis detection unit.

Dr. Magney is survived by his wife, Ruth, and four sons, Roy, Robert, Paul, and Mark.

RAYMOND D. J. ALBRECHT, M.D.

Dr. Raymond J. Albrecht, 40, St. Paul specialist in obstetric and gynecology, died September 23. He was born in St. Paul and lived there all his life. Dr. Albrecht pioneered natural childbirth at St. Joseph's Hospital in St. Paul, and was on the staff of this hospital in addition to being a clinical professor of obstetrics and gynecology at the University of Minnesota.

He was a member of the Ramsey County Medical Society, a diplomat of the American Board of Obstetrics and Gynecology, a member of the American Medical Association and the Minnesota State Medical Association.

Dr. Albrecht is survived by his wife, Judith and four children, Lisa, Katherine, Mary and Paul.

HENRY D. DIESSNER, M.D.

Dr. Henry D. Diessner, 86, Minneapolis urologist, died September 21. He attended the University of Minnesota Pre-med School and graduated from Hahnemann Medical College in Philadelphia in 1909.

A former chief of staff of St. Barnabas Hospital, Dr. Diessner was a member of the Twin Cities Urological Society, the North Branch of the American Urological Society, the American Medical Association and the Hennepin County Medical Society. He was a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Diessner is survived by his wife, Eleanor, daughters Sylvia, Viola, Gladys and Laura. Dr. William Diessner of Waconia is his brother.

FRANK E. ELLISON, M.D.

Dr. Frank E. Ellison, 88, of Monticello died September 19. He participated actively in the civic life of Monticello and had been a member of the school board for 30 years, serving as its president for 27 years. In 1959, the high school awarded him a special award as the outstanding citizen in Monticello. In 1954 he was among a select group of citizens who were given a citation by Hamline University "for achievements and service in medicine and church leadership."

Educated at Hahnemann Medical School in Chicago, he was a member of the American Medical Association and the Wright County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife, Caroline, and sons, John and Everett.

WILLIAM B. EILERS, M.D.

Dr. William Benit Eilers, 36, died September 7. He was born in Brooklyn, Iowa and attended Fairmont and Redwood Falls schools, graduating from the University of Minnesota Medical School in 1960.

After his discharge from the army, Dr. Eilers joined Cairns Clinic in Redwood Falls in 1963. He was a member of the MidMinnesota County Medical Society and the American Medical Association and a Residency Member of the Minnesota State Medical Association.

Dr. Eilers is survived by his wife, Marilyn, and children, Lynda, Kathryn, William, Kristin, Timothy and Patricia.

MANLEY F. JUERGENS, M.D.

Dr. Manley F. Juergens, 50, Stillwater physician, died September 5. He was reared in Belle Plaine, Minnesota, and graduated from the University of Minnesota Medical School in 1945. He served in the Army Air Force and practiced medicine in Minneapolis and Thief River Falls before moving to Stillwater in 1949 where he became a partner in the Stillwater Clinic.

He was a member of the Minnesota State Medical Association, Wakota County Medical Society, American Academy of Family Practitioners, Minnesota Academy of Family Practice, American Medical Association, Minnesota Heart Assocation, and the Lakeview Hospital Medical Staff of which he was a former chief of staff.

Dr. Juergens is survived by his wife, Harriet, and three sons, Hugh, Steven and Mark. Dr. H. M. Juergens of Belle Plaine is his father and Dr. John L. Juergens of the Mayo Clinic, Rochester, his brother.

CHARLES F. REICHELDERFER, M.D.

Dr. Charles Reichelderfer, Staples physician and surgeon for many years, died July 17. He was 70 years of age. He received his medical education at Northwestern University Medical School in Chicago, and after interning, moved to Staples where he opened his medical office in 1927 where he continued his medical practice until his death.

He was known in Staples as the "Father of the Vocational School" being one of the first to recognize the need for vocational training. He served as chief of staff at the Staples Municipal Hospital, as Health Officer and Registrar of Vital Statistics for many years, and was a member of the American Medical Association and the Upper Mississippi Medical Society and a Life Member of the Minnesota State Medical Association.

Dr. Reichelderfer is survived by his wife, Lylla, two daughters, Elaine and Cynnthia, and one son, Dr. Charles F. Reichelderfer, Jr. of Hyattsville, Maryland.

RICHARD E. ANDERSON, M.D.

Dr. Richard E. Anderson, Willmar physician, died August 26. He was 88 years of age. He went to Willmar in 1921 from Chicago where he had been engaged as a medical doctor for an insurance firm, and practiced there until 1951. The next two years he resided in Rock Island, Illinois, before returning to Willmar to continue his practice until his retirement in 1963.

Born in Rock Island, Illinois and graduating from the University of Illinois Medical School, Dr. Anderson interned at the County Hospital in Chicago.

He was a member of the American Medical Association and the Mid Minnesota Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association. He is also a 50-year member of the Masonic Order and a past master of the Sharon Lodge, A.F.&A.M.

Dr. Anderson is survived by his wife, Caroline.

NORMAN H. BAKER, M.D.

Dr. Norman H. Baker, 67, Fergus Falls physician and surgeon, died September 23, on a hunting trip near Baudette, Minnesota. Educated at the University of Minnesota Medical School, Dr. Baker spent his entire private medical career in Fergus Falls.

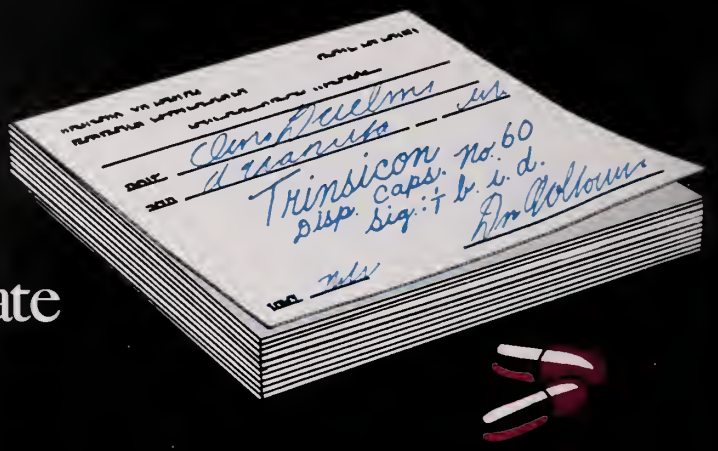
He was a member of the American Medical Association, the Minnesota State Medical Association and the Park Region District and County Medical Society.

Dr. Baker is survived by his wife, Dr. Jeanette Baker, two sons, Dr. Richard Baker and Dr. Norman Baker, and a daughter, Dr. Jean Trousdale.

Iron therapy for anemia is almost as old as history itself

Celsus's empirical use of iron

Aulus Cornelius Celsus recommended an unusual form of iron therapy for the treatment of enlarged spleens—the oral administration of water that blacksmiths had used for dousing white-hot iron.



For more modern anemia therapy

Trinsicon®

Hematinic Concentrate with Intrinsic Factor

(See reverse side for prescribing information.)

Trinsicon®
Hematinic Concentrate with Intrinsic Factor

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	240 mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin	7.5 mcg.

(The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)

Iron, Elemental (as Ferrous Fumarate)	110 mg.
Ascorbic Acid (Vitamin C)	75 mg.
Folic Acid	0.5 mg.

Indications: Trinsicon is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia. Therapeutic quantities of hematopoietic factors that are known to be important are present in the recommended daily dose.

Vitamin B_{12} with Intrinsic Factor—When secretion of intrinsic factor in gastric juice is inadequate or absent (e.g., in Addisonian pernicious anemia or after gastrectomy), vitamin B_{12} in physiological doses is absorbed poorly, if at all. The resulting deficiency of vitamin B_{12} leads to the clinical manifestations of pernicious anemia. Similar megaloblastic anemias may develop in fish tapeworm (*Diphyllobothrium latum*) infection or after a surgically created small-bowel blind loop; in these situations, treatment requires freeing the host of the parasites or bacteria which appear to compete for the available vitamin B_{12}. Strict vegetarianism and malabsorption syndromes may also lead to vitamin B_{12} deficiency. In the latter case, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient.

Potency of intrinsic factor concentrates is determined physiologically, i.e., by their use in patients with pernicious anemia. The liver-stomach concentrate with intrinsic factor and the vitamin B_{12} contained in two Pulvules Trinsicon provide 1½ times the minimum amount of therapeutic agent which, when given daily in an uncomplicated case of pernicious anemia, will produce a satisfactory reticulocyte response and relief of anemia and symptoms.

Concentrates of intrinsic factor derived from hog gastric, pyloric, and duodenal mucosa have been used successfully in patients who lack intrinsic factor. For example, Fouts *et al.* maintained patients with pernicious anemia in clinical remission with oral therapy (liver extracts or intrinsic factor concentrate with vitamin B_{12}) for as long as twenty-nine years.

After total gastrectomy, Ficarra found multifactor preparations taken orally to be "just as effective in maintaining blood levels as any medication that has to be administered parenterally." His study was based on twenty-four patients who had survived for five years after total gastrectomy for cancer and who had been taking two Pulvules Trinsicon daily.

Folic Acid—Folic acid deficiency is the immediate cause of most, if not all, cases of nutritional megaloblastic anemia and of the megaloblastic anemias of pregnancy and infancy; usually, it is also at least partially responsible for the megaloblastic anemias of malabsorption syndromes, e.g., tropical and nontropical sprue.

It is apparent that in vitamin B_{12} deficiency (e.g., pernicious anemia), lack of this vitamin results in impaired utilization of folic acid. There are other evidences of the close folic acid-vitamin B_{12} interrelationship: (1) B_{12} influences the storage, absorption, and utilization of folic acid, and (2), as a deficiency of B_{12} progresses, the requirement for folic acid increases. However, folic acid does not change the requirement for vitamin B_{12}.

Iron—A very common anemia is that due to iron deficiency. In most cases, the response to iron salts is prompt, safe, and predictable. Within limits, the response is quicker and more certain to large doses of iron than to small doses.

Each Pulvule Trinsicon furnishes 110 mg. of elemental iron (as ferrous fumarate) to provide a maximum response.

Ascorbic Acid—Vitamin C plays a role in anemia therapy. It augments the conversion of folic acid to its active form, folinic acid. In addition, ascorbic acid promotes the reduction of ferric iron in food to the more readily absorbed ferrous form. Severe and prolonged vitamin C deficiency is associated with an anemia which is usually hypochromic but occasionally megaloblastic in type.

Contraindications and Precautions: Anemia is a manifestation that requires appropriate investigation to determine its cause or causes.

Folic acid *alone* is unwarranted in the treatment of pure vitamin B_{12}-deficiency states, such as pernicious anemia. Indeed, the use of folic acid in large doses in pernicious anemia without adequate vitamin B_{12} may result in hematologic remission but neurological progression.

As with all preparations containing intrinsic factor, resistance may develop in some cases of pernicious anemia to the potentiation of absorption of physiological doses of vitamin B_{12}. If resistance occurs, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient. No single regimen fits all cases, and the status of the patient observed in follow-up is the final criterion for adequacy of therapy. Periodic clinical and laboratory studies are considered essential and are recommended.

In extremely rare instances, skin rash suggesting allergy has been noted following the oral administration of liver-stomach material. Allergic sensitization has been reported following both oral and parenteral administration of folic acid.

Hemochromatosis and hemosiderosis are contraindications to iron therapy.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastrointestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects in the iron-sensitive patient.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500 and in Identi-Dose® (unit dose medication, Lilly) in boxes of 100.

Encounter under the Scanning Electron Microscope

SEM reveals changes in *E. coli* exposed to antibacterial agents

The Scanning Electron Microscope (SEM) is the only instrument which gives 3-dimensional views on a microscopic level. This permits the surface morphology of microorganisms to be observed in detailed perspective. Changes in surface morphology of *E. coli* exposed to various antimicrobial agents are seen on the following page. An SEM photomicrograph of normal control *E. coli* appears above.

Different modes of antibacterial action — Similar changes in morphology

As part of a series of experiments,[1-3] strains of *E. coli* proven susceptible to each antibacterial agent were exposed to 1 MIC of the respective antibacterials for a three-hour period. Included were cell-wall-active drugs, ampicillin and cephalothin; a drug interfering with intracellular protein synthesis, tetracycline; and a chemical agent which acts by interference with para-aminobenzoic acid, sulfamethoxazole.

As seen above, elongation of the bacilli, mid-cell defects and spheroplast-like forms may be appreciated with the SEM technique. These changes in bacterial morphology were similar... regardless of the antibacterial agent used and irrespective of its mechanism of action.

"At present, the significance of these observations in clinical infection must be considered with caution, but it is hoped that these data will stimulate a reevaluation of present concepts of the nature and role of morphological variants of bacteria exposed to a variety of antibacterial factors."[2]

It should be noted that no clinical conclusions can be drawn from this study, as it is not always possible to extrapolate *in vitro* data to humans.

L.: Scientific Exhibit presented at the 25th American Medical Association Clinical Convention, New Orleans, La., Nov. 28-Dec. 1, 1971. **2.** Klainer, A. S., and Perkins, R. L.: *Antimicrob. Agents Chemother.*, *1*:164, 1972. **3.** Klainer, A. S.: Data on file, Hoffmann-La Roche Inc., Nutley, N.J.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Acute, recurrent or chronic nonobstructed urinary tract infections (primarily pyelonephritis, pyelitis and cystitis) due to susceptible organisms. **Note: Carefully coordinate *in vitro* sulfonamide sensitivity tests with bacteriologic and clinical response; add aminobenzoic acid to follow-up culture media. The increasing frequency of resistant organisms limits the usefulness of antibacterials including sulfonamides, especially in chronic or recurrent urinary tract infections.** Measure sulfonamide blood levels as variations may occur; 20 mg/100 ml should be maximum total level.

Contraindications: Sulfonamide hypersensitivity; pregnancy at term and during nursing period; infants less than two months of age.

Warnings: Safety during pregnancy has not been established. Sulfonamides should not be used for group A t hemolytic streptococcal infections and will not eradicat o prevent sequelae (rheumatic fever, glomerulonephritis) of c infections. Deaths from hypersensitivity reactions, agranulo t sis, aplastic anemia and other blood dyscrasias have bee r ported and early clinical signs (sore throat, fever, pallor, pu or jaundice) may indicate serious blood disorders. Frequent B and urinalysis with microscopic examination are recomme e during sulfonamide therapy. Insufficient data on children u e six with chronic renal disease.

Precautions: Use cautiously in patients with impaired or hepatic function, severe allergy, bronchial asthma; in glu 6-phosphate dehydrogenase-deficient individuals in whom related hemolysis may occur. Maintain adequate fluid inta prevent crystalluria and stone formation.

Adverse Reactions: *Blood dyscrasias* (agranulocyt

Encounter in Clinical Practice

Control of primary bacterial offenders

Antibacterial Gantanol® (sulfamethoxazole) controls susceptible strains of *E. coli* and other gram-negative and gram-positive organisms often implicated in acute nonobstructed pyelonephritis and cystitis.

Prompt antibacterial blood and urine levels

In from 2 to 3 hours after the initial 2-Gm adult dose, antibacterial levels are present in both the blood and urine.

B.I.D./T.I.D. dosage for around-the-clock coverage

Subsequent 1-Gm doses provide up to 12 hours of antibacterial coverage. More severe u.t.i. may require a q. 8 h. dosage regimen. Either schedule provides coverage during the waking and sleeping hours—especially important during hours of sleep when normal urinary retention tends to favor bacterial proliferation.

Also effective in nonobstructed chronic and recurrent u.t.i.

It is not uncommon for the elderly and the debilitated to develop chronic and/or recurrent nonobstructed urinary tract infections such as pyelonephritis and cystitis. Such cases often respond satisfactorily to Gantanol. The increasing frequency of resistant organisms is a limitation of usefulness of antibacterial agents including sulfonamides, especially in chronic or recurrent u.t.i.

Your Option: Tablets or Suspension

Either dosage form—the Tablets or the pleasant-tasting, cherry-flavored Suspension—can provide the dependable antibacterial activity necessary to control susceptible nonobstructed cystitis and pyelonephritis. Symptomatic improvement may usually be expected in 24 to 48 hours. The usual precautions with sulfonamide therapy should be observed, including adequate fluid intake. Gantanol (sulfamethoxazole) is generally well tolerated with relative freedom from complications; the most common side effects are nausea, vomiting and diarrhea. Frequent c.b.c.'s and urinalyses with microscopic examination are recommended.

In nonobstructed cystitis and pyelonephritis due to susceptible organisms

Gantanol®
(sulfamethoxazole)
Basic Therapy

stic anemia, thrombocytopenia, leukopenia, hemolytic ane-
purpura, hypoprothrombinemia and methemoglobinemia);
gic reactions (erythema multiforme, skin eruptions, epider-
necrolysis, urticaria, serum sickness, pruritus, exfoliative
natitis, anaphylactoid reactions, periorbital edema, conjunc-
and scleral injection, photosensitization, arthralgia and
gic myocarditis); *gastrointestinal reactions* (nausea, emesis,
minal pains, hepatitis, diarrhea, anorexia, pancreatitis and
natitis); *CNS reactions* (headache, peripheral neuritis, men-
lepression, convulsions, ataxia, hallucinations, tinnitus, ver-
and insomnia); *miscellaneous reactions* (drug fever, chills,
nephrosis with oliguria and anuria, periarteritis nodosa and
phenomenon). Due to certain chemical similarities with
e goitrogens, diuretics (acetazolamide, thiazides) and oral
glycemic agents, sulfonamides have caused rare instances
oiter production, diuresis and hypoglycemia as well as thy-
roid malignancies in rats following long-term administration. Cross-sensitivity with these agents may exist.

Dosage: Systemic sulfonamides are contraindicated in infants under 2 months of age (except adjunctively with pyrimethamine in congenital toxoplasmosis).

Usual adult dosage: 2 Gm (4 tabs or teasp.) initially, then 1 Gm *b.i.d.* or *t.i.d.* depending on severity of infection.

Usual child's dosage: 0.5 Gm (1 tab or teasp.)/20 lbs of body weight initially, then 0.25 Gm/20 lbs *b.i.d.* Maximum dose should not exceed 75 mg/kg/24 hrs.

Supplied: Tablets, 0.5 Gm sulfamethoxazole; Suspension, 0.5 Gm sulfamethoxazole/teaspoonful.

Special Article

Acute Myocardial Infarction, 1970

Evaluation by Medical Audit in Five Minnesota Hospitals

WILLIAM R. FIFER, M.D.

INTERNAL MEDICAL AUDIT is being used by five Minnesota community hospitals to determine the continuing education needs of their medical staffs in a program sponsored by the University of Minnesota Division of the Northlands Regional Medical Program. The process involves six steps:

1. Setting standards of optimal achievable care for a given illness, operation, or condition. This function is performed by the medical staff audit (professional activities) committee.
2. Reviewing by the consecutive case method the actual care of that illness. This function is performed by review of displays of patterns of care prepared by the Medical Records Department.
3. Comparing optimal care with actual care to look for gaps, a function of the medical staff audit committee.
4. Translating these gaps into educational objectives which become the basis for the hospital's continuing medical education program. This is done by the medical staff education committee under the leadership of the Director of Continuing Medical Education.
5. Establishing "monitor parameters" for the illness studied to permit rapid evaluation of compliance with standards on a periodic basis. This procedure is set up by the audit committee.
6. Scheduling re-audit of the illness studied at an appropriate interval after the educational program, to see if learning (behavioral change) occurred. This step closes the loop to the beginning of the audit cycle.

Each of the five participating hospitals is encouraged to internalize the audit procedure so that they are working with their own standards, their own cases and their own education. The medical staffs are organized differently and have proceeded independently to select their choice of diseases to study. We have intentionally avoided suggesting external standards or some universal "gold standard" for each disease, because the process of standard setting is educational in itself.

As coordinator of their efforts, however, we could not resist the temptation to pool data for certain common diseases, hoping we would all learn more in the process than if each hospital made its own studies. Therefore, we decided to have each of the five medical staff audit committees respond to a list of 23 questions* about myocardial infarction to derive comparative and group standards, or "pattern criteria." We then reviewed all the cases of acute myocardial infarction in 1970 in the five participating hospitals to formulate comparative and group care patterns. Results of these comparisons are being reported here.

The important achievement is the *process* by which medical care is appraised—the *content* is incidental. We selected myocardial infarction because it is a common and serious disease in our society, and serves to display the practice patterns of Minnesota doctors in community hospitals. The data are crude, but as true as can be obtained by mass analysis techniques without reviewing every chart in detail. These crude data were fed back to each cooperating hospital to help them identify their own continuing education needs.

The Study Context

The five Minnesota Audit Hospitals in this year's program are scattered about the state in small (circa 10,000 population) cities. The smallest hospital has 17 medical staff members and 64 acute beds; the largest has 31 doctors and 185 acute beds. We have a total of 142 physicians and 663 acute beds to share data; a sizable community "teaching hospital" in a functional sense. Each hospital has a Director of Continuing Medical Education (DCME) one day a week. Three of the five hospitals are long-time subscribers to the PAS/MAP computer-assisted data storage and retrieval system sponsored by the Commission on Professional and Hospital Activi-

Dr. Fifer is Director, University Division, Northlands Regional Medical Program.

*See Appendix, page 1075.

ties in Ann Arbor, Michigan. In those hospitals, we used only the computer-generated forms in reviewing care in this study. These forms greatly simplify record review, but allow a little "dirtier" data than when each medical record is reviewed completely. This is because PAS/MAP review assumes that each case listed as an acute myocardial infarction has satisfied enough diagnostic criteria to be so coded by the attending physician at the time of discharge. Such a review accepts the diagnosis as given, rather than examining the diagnostic process. When one reviews actual medical records, however, he begins to "toss out" cases included in that diagnostic code because, for example, the electrocardiographic charges are non-specific, and the rise in serum enzymes is equivocal. Any review of patient care is only as good as the medical record, and when such a review is based on PAS/MAP printouts, it also depends heavily on the accuracy of preparation of the case abstract by medical records personnel. One must carefully define the diagnosis of even such an apparently noncontroversial disease as myocardial infarction in order to assure uniformity of the data.

Presented, then, is a data display gleaned from PAS/MAP printouts alone, and the questions asked are limited to those which the PAS/MAP forms can answer. In so doing, we are only presenting one-third of the total information needed to appraise medical care, as we divided information needs into three parts: (1) that information which can be retrieved by medical records personnel (given the right questions by the medical staff) from PAS/MAP printouts; (2) that information which is retrievable by medical records personnel from the medical record itself (this includes many items in the history and physical examination); and (3) that information which only the medical staff can appraise, such as appropriateness of antibiotic therapy.

Our study included 424 cases, and represents all patients discharged from our five audit hospitals in calendar year 1970, with the exception of our smallest hospital, where we studied all of 1970 with ten months of 1971 to get a reasonable number of consecutive cases (78). One hospital did not have an intensive coronary care unit (ICCU) during 1970, and another had such a unit in operation for only half of the year. The composition of the medical staffs varies greatly and this, along with rules about ICCU care, affects such things as the consultation rate. Thus some of our hospital staffs are predominantly general (family) practitioners, while others consist mostly of specialists, with the internist assuming the care of medical illnesses of adults. Sometimes one or two internists function primarily as cardiologists, and care for all the patients with acute myocardial infarction. At times, the ICCU rules decided by the medical staff provide for mandatory consultation by a cardiologist in certain situations. In one hospital, a full-time, hospital-based internist is director of the ICCU. All of these variations tend to affect the behavior of the medical staff and show up as differences in such items as consultation rate. These local practice patterns tend to make data such as the consultation rate incomparable, but reinforce the importance of having each staff set its own standards and perform its own internal medical audit.

Pattern Criteria

As mentioned, we asked the audit committee of each of the five medical staffs to answer 23 questions in order to derive group and comparative pattern criteria.

Some questions (5, 7, 12 and 17) were answered virtually identically by all five audit committees indicating complete agreement on a standard. They all felt that 100% of the patients should have an electrocardiogram and a repeat unless they died within hours, an event which precludes a repeat or comparison tracing. They all felt that 95% to 100% of all patients with acute myocardial infarction should be treated in an ICCU. They agreed it was important to diagnose the anatomic site of the infarction (though as we shall see, most of the time they did not actually specify the site in their discharge diagnosis). Finally, they felt that all of these patients should have a chest Xray during their hospitalization.

Eleven questions provoked answers in substantial agreement, though not complete (questions 1, 2, 3, 6, 11, 11a, 13, 14, 20, 22 and 23). For example, all five committees agreed closely on the median length of stay (LOS) (average 21.4 days —range 20 to 24 days). They felt the death rate should range from 15% to 20% (average 18.6%). They believed that 5% to 15% (average 9%) of patients should require pacemaker utilization for optimal care. They believed steroid therapy would be required seldom (3% to 10%)

and felt the same way about antibiotics (2% to 10%).

Nine questions, however, produced answers which were in substantial disagreement. Representative questions from this group were:

4. Consultation percentage (10% to 100%).
8. Percent of patients treated with oxygen (50% to 100%).
9. Percent of patients treated with anticoagulants (30% to 90%).
10. Percent of patients treated with cardiac regulatory drugs (50% to 80%).
15. Percent of patients having a rectal or pelvic examination at some time during admission (0% to 100%).
19. Percent of patients receiving coronary vasodilator drugs (0% to 50%).

To answer these questions, the medical staff committees drew upon their knowledge and opinions regarding these matters, and since there continues to be controversy in medicine regarding issues such as the use of anticoagulant therapy in acute myocardial infarction, we cannot expect uniform opinions (standards) to emerge. Likewise, there must be differences of opinion as to whether giving oxygen benefits these patients (and why) or whether coronary vasodilators (such as nitroglycerine and its analogs) are contraindicated. Most doctors agree that coronary vasodilators are useful for the patient with angina or coronary insufficiency, and may use them until they are convinced the patient has indeed suffered a myocardial infarction, and then discontinue them. These discussions (and many more) provoked by criteria setting, are inherently educational to the medical staff committees.

Profiles of Care

We studied both PAS/MAP printouts (mostly) and patient records (less) from many perspectives to describe the profiles of care in these 424 patients in five hospitals. Their median age was 66 years and 67% of them were men. The length of stay (median) was 20.4 days, with a range of 17 to 25 days. The death rate average 23.8%, but varied significantly from 12.5% to 40%. The hospital with the highest death rate did not have an ICCU in operation during 1970. There was no correlation between the consultation rate and the death rate; in fact the hospitals with the lowest death rate (12.5%) and the highest death rate (40%) had very similar consultation rates (34% and 30% respectively). Also Hospital "D" with a low consultation rate (7.2%) had the second lowest death rate (17.8%) (Table 1). These data illustrate that process cannot always be translated to outcome.

TABLE 1
Acute Myocardial Infarction, 1970
Patterns of Care

Item	Hospital A	B	C	D	E	Ave.
Median LOS (Days)	18	21	25	21	17	20.4 Days
Death Rate (%)	22	40	12.5	17.8	26	23.8%
Consultation Rate (%)	42	30	34	7.2	2.6	23%

The use of ICCU's in Minnesota hospitals is widespread, with 105 in operation out of 165 short-term general hospitals. The Minnesota Heart Association, in cooperation with the Northlands Regional Medical Program, has operated excellent training centers for ICCU nurses in multiple sites. A cooperative study by 64 participating ICCU's reported a hospital mortality rate of 18.3% for all acute myocardial infarction patients from July 1, 1970 to July 1, 1971. In the four audit hospitals with ICCU's 86% of the acute myocardial infarction patients were treated in these units, and all these were monitored. When we determined what percent of patients admitted to ICCU's turned out to have an acute myocardial infarction, we found a consistent figure of 44% (43, 45 and 45). This agrees well with the cooperative study of the Minnesota Heart Association which found 41% of 5,791 patients admitted to 64 participating ICCU's proved to have an acute myocardial infarction. Such consistency of data is most useful in planning such resources as ICCU beds and their staffing requirements. A total of 50 patients in this study (11.4%) were not treated in ICCU's (in the four hospitals that had ICCU's) and the same number did not receive the benefit of monitoring. Of these 50, 12 (24%) died, but there was great variation (from 14% to 45%), and our numbers are too small in this study to assess the increased risk of not being admitted to an ICCU.

When it came to "working up" the acute myocardial infarction patient, our doctors varied a lot. Although 79% of the patients had enzymes studied (SGOT, LDH, CPK) the range was from 57% to 92%. The blood sugar was determined in only 64% of the patients, again with a wide range of 49% to 90%. Cholesterol and/or lipid profiles were determined in only 49% of these patients. Physician behavior seems not to have been unduly influenced by automated "packages" of lab tests in these five hospitals. We found that Hospital "D," with the highest curiosity about the

patient's blood sugar (90%) and enzymes (92%), had the lowest curiosity about his cholesterol and/or lipids (36%) (Table 2).

TABLE 2
Acute Myocardial Infarction, 1970
Patterns of Care

Item	Hospital A	B	C	D	E	Ave.
Enzymes (%)	79	51	85	92	88	79%
FBS (%)	55	49	75	90	50	64%
BUN (%)	50	49	75	88	63	65%
Chol. Lipids (%)	49	48	55	36	57	49%
Oxygen Ther. (%)	84	0*	73	38.5	76	54%

*Recording Error?

There was a great difference in the use of oxygen. While overall 54% of the patients received oxygen, its use varied from 38% to 84%. We believe sharing these data with our hospital staffs will make them ask, "What is the right answer?" and set in motion education efforts to find out.

Location of Infarct

What is physician behavior in regard to stating the anatomic site of myocardial infarcts and does it make any difference? In answering this latter question to devise pattern criteria, most staffs said "yes," but they do not diagnose the site very consistently on the face sheet. Again, there was a great variation in behavior: Hospital "A" specified the site 86% of the time, whereas Hospital "B" *did not* specify the site 87% of the time. Altogether, anterior wall infarct was the most common site specified (24%) but "site not specified" was even more common (46%). When we look at these data we see that different physicians must be using different electrocardiographic criteria for identifying the site, and these variances are compounded by how many different physicians read the tracings. Note in Table 3 that 27% of the infarcts in Hospital "A" were classified as "inferior," while Hospital "C" classified none as "inferior." Hospital "C" said 22% were "lateral" while Hospital "E" said none were. Hospital "A" said no "posterior," while Hospital "E" said 21% were posterior, and both of these hospitals showed a great tendency to classify site. Data like this suggest that until we have uniform criteria for specifying the anatomic site of an infarct applied uniformly by all physicians who read EKG's, we will never be able to derive any meaningful correlation between site and prognosis (or complications). The Minnesota Heart Association Cooperative Study found that anterior wall infarction represented 48% of their 2,403 cases, while 30% had inferior wall infarction and 22% were subendocardial. Their hospital mortality rate was: anterior 23.5%, inferior 18%, and subendocardial 8%. This indicates an apparent prognostic difference determined by site. The Minnesota Heart Association Study also shows that anterior wall infarcts tend to die in the ICCU 78% of the time rather than after they are transferred out of the unit. Subendocardial infarcts, however, seem to be under greater increased risk, proportionately, after they leave the ICCU. But obviously the *extent* of the infarction is likewise important in determining survival, because most ICCU deaths are due to "pump failure" (72% in the Minnesota Heart Association Study). After leaving the ICCU, however, (a time during which a quarter of the deaths occur, according to the MHA Study) dysrhythmia deaths became almost as frequent (43%) as pump failure deaths. These data suggest we should know both the site and extent of infarction to predicate the likelihood of death both during and after the ICCU stay.

TABLE 3
Acute Myocardial Infarction, 1970
Patterns of Care
Location of Infarct (Expressed as Percent)

	Hospital A	B	C	D	E	Average (Range)
Anterior	23.5	10	41	22	25	24 (10-41)
Posterior	0	0	12.5	5.4	21	8 (0-21)
Inferior	27	3	0	3.6	6.5	8 (0-27)
Lateral	4.7	0	22	1.8	0	5.7 (0-22)
Subendocardial	3.5	0	1	0	4	1.7 (1-4)
Multiple Sites	29	0	0	0	5	7 (0-29)
Not Specified	14	87	24	67	37	46 (14-87)

When we look for other coded diagnoses on the face sheet such as shock, congestive heart failure and dysrhythmias, we find them infrequently; yet study of charts indicated they were present much more often. Depending on one's definition of how many runs of premature ventricular contractions make a dysrhythmia, this diagnosis appears almost universal from a study of the "rhythm strips" in the ICCU nurse's notes. Likewise, our doctors rarely diagnosed "defibrillation" such that the record librarian could spot it and enter it as a codeable operation.

How often should physicians manage infarct patients to remain competent? Medical staffs should address themselves to such questions. The range of cases per doctor in our study in 1970 was from one to 24, and each of the four hospitals for which we have information had at least one medical staff member who cared for only one

case in that year. It seems likely that if six liver biopsies were to be done annually in a hospital with six physicians on the staff, the staff would get together, choose the most able among them to perform the procedure, and have him do all six rather than each doing one per year. From such a division of labor we might expect less complications and more proficiency.

Utilization review (retrospective) is a by-product of such a review of cases as this. We found considerable difference in "long stay" (over 30 days) patients from 26% in Hospital "C" to 6.5% in Hospital "E." These patterns remained consistent when we selected long stay patients with no secondary diagnoses, ranging from 12.5% in Hospital "C" to 0% in Hospital "E." Before we get carried away by the siren song of reduced cost through reduced utilization, however, we note that Hospital "C," with its long stay, produced the lowest death rate (12.5%) of all (Table 4).

TABLE 4
Acute Myocardial Infarction, 1970
Patterns of Care

Item	Hospital A	B	C	D	E	Total or Ave.
Percent of Long Stay (LOS > 30 Days) Pts.	—	13	26	8	6.5	13 (8-26)
Percent of Long Stay (LOS > 30 Days) Pts. With no Secondary Diag.	—	5	12.5	1.8	0	4.8 (0-13)
Death Rate Percent	22	40	12.5	17.8	26	23.8

Performance of rectal and pelvic examinations showed behavioral differences among the medical staffs of the hospitals in the study. In Hospital "C" 7% of the patients got rectal and 1% got pelvics. In Hospital "E," however, 30% of the patients got rectals. There is no "right" answer, but if the infarct patient presented with metastatic rectal carcinoma six months after his hospitalization, we would all be chagrined.

Seventeen percent of all these patients had an elevated blood sugar, but in only 40% of this group was diabetes diagnosed. It is known that transient hyperglycemia occurs occasionally immediately after an infarct, presumably due to adrenal medullary hyperactivity. It is also known that most ICCU patients have a "keep open" I.V. of 5% glucose running (in our series 74%). But until we have a chance to follow these patients, we should list "elevated blood sugar" on the problem list in order to make sure we satisfy ourselves regarding its investigation in future encounters with the patient.

Identifying Gaps

By comparing pattern criteria with profiles of care, medical staffs can identify "gaps" between what they consider optimal care and the actual care delivered. As seen in Table 5, in certain areas no gap exists. For example, the standard set for median length of stay was 21.4 days, and the actual median stay was 20.4 days. In some very important areas, significant gaps exist. For example, Hospital "B" thought its myocardial infarction death rate should be 15% and it proved to be 40%. Learning of such *outcomes* as a 40% death rate motivates a medical staff to look at the *process of care* to see if they can improve their figure, in the same way that a golfer who shoots 90 on a par 72 course analyzes his game to seek improvement in his score.

TABLE 5
Acute Myocardial Infarction, 1970
Identifying Gaps

	Ideal Criteria	Actual Pattern
Length of Stay	21.4	20.4
Death Rate, Hospital B	15%	40%
Cholesterol/Lipid, Hospital D	100%	36%
Chest Xray	100%	83%

Review of blood chemistries done in "working up" infarct patients also discloses major discrepancies between standards set and actual behavior. For example, Hospital "D" set as a pattern criterion the performance of cholesterol/lipid patterns in 100% of its myocardial infarction patients, but did so in only 36%. Gaps may exist for all hospitals within the study which "cancel out" when looked at as a group. This is seen in the use of anticoagulant therapy: The "group standard" was to administer anticoagulants to 68%, yet among the individual hospitals both positive and negative discrepancies exist between the standard set and the care delivered.

All five hospitals agreed that 100% of all myocardial infarction patients should have a chest Xray, based upon sound medical reasoning which seems universally shared, yet about 17% of those patients failed to get a chest Xray for one reason or another.

Educational Objectives

The audit committee, having identified gaps between optimal and actual performance, asks the education committee to translate these gaps into educational objectives to guide a program of hospital-based continuing medical staff education

based on demonstrated knowledge needs. The Director of Continuing Medical Education functions as staff to the education committee in implementing this continuing education program.

A sample educational objective might be: "Following a medical staff meeting devoted to learning the importance of lipid phenotypes and their treatment and the association of abnormal lipid metabolism to the risk of coronary atherosclerosis, the medical staff will determine cholesterol/lipids in 95% of all patients with acute myocardial infarction, and diagnose hyperlipidemia on the face sheet in 75% of the patients in whom it has been demonstrated."

One can easily formulate similar educational objectives related to these gaps: (Table 6)

(1) Fourteen percent of the patients in these five hospitals never get into the ICCU.
(2) Fifty percent of these patients in Hospital "E" did not have blood glucose determined.
(3) Forty-nine percent of these patients in Hospital "B" did not have enzymes determined.
(4) Sixty-two percent of these patients in Hospital "D" did not receive oxygen therapy.
(5) Eighty-seven percent of the infarcts at Hospital "B" were diagnosed as "site not specified."
(6) Twenty-three percent of the myocardial infarction patients in Hospital "D" did not have a chest Xray during their admission.

TABLE 6
Acute Myocardial Infarction, 1970
Educational Objectives

1. **Get all patients into the ICCU (14% did not).**
2. **Get blood sugar in all MI patients (50% did not).**
3. **Get enzymes on 100% (49% in Hospital B did not).**
4. **Give oxygen therapy to all patients (62% in Hospital D did not get oxygen therapy).**
5. **Specify the site 100% of the time (87% in Hospital B were diagnosed as "site not specified.")**
6. **Get chest Xrays in all (23% in Hospital D did not get chest Xrays).**

Some gaps (knowledge needs) are common to all five hospitals, while others are limited to one or two. Each educational program must be individually tailored to meet the knowledge needs of the hospital.

The medical audit system used in this study provides a means of objectively evaluating the education program in terms of behavioral change by simply re-auditing myocardial infarction care (or any specific element of it) at a suitable interval after the education effort. We know from our 1970 study that only 36% of the acute myocardial infarction patients in Hospital "D" had cholesterol and/or lipids determined. After Hospital "D" conducts an education program whose objective is to increase this level of determinations, the level will either go down, stay the same, or go up. Only with the latter result can one claim that the education program modified physician behavior favorably.

Summary

We have presented a look at the use of internal medical audit to determine continuing medical educational needs in five community hospitals in Minnesota—using a study of all myocardial infarction patients in these hospitals in 1970 as an example. There are limitations to using PAS/MAP printouts alone to garner such statistics: These limitations are related to: (1) the accuracy of input (the case summary prepared by the medical records personnel) and (2) the acceptance of the diagnosis as given without critically examining the evidence upon which it is based.

Such a study, however, displays gaps which the individual hospital medical staffs may wish to pursue by appraisal of all or any part of such a subject as myocardial infarction. We believe these displays of patterns of care prepared by medical records personnel permit the medical staff audit committee to "zero in" on problem areas. Busy doctors cannot take the time away from patient care to review all 424 cases of myocardial infarction by reviewing every single chart. They can, by learning to review patterns of care, select those cases, those areas, which require further analysis to improve care of this disease in their institution by applying *directed* continuing education.

We have little ability to study *diagnostic outcomes* or *process* by this method, but we feel satisfied that such an audit as the one presented does identify some *therapeutic outcomes* and scrutinizes the *therapeutic process* in considerable detail. It permits the medical staff to "take inventory" of specific areas of care, and allows them to select "critical incidents" of care for study by review of the entire medical record.

This study illustrates how the medical staff of the community hospital can determine its knowledge needs to construct a relevant, on-site pro-

gram of continuing education whose effectiveness can be evaluated by re-audit after the educational effort has occurred. We hope studies like this also provide feedback to medical educators who have often constructed curricula with little information about the actual behavior of physicians in community hospitals.

APPENDIX

Pattern Criteria for Acute Myocardial Infarction

1. What percent of the patients we admit to the ICCU should turn out to have an acute myocardial infarction?
2. What should be the median (50th percentile) stay for acute myocardial infarction patients?
3. What should the death rate be?
4. What percent of acute myocardial infarction patients should have consultation?
5. What percent should have an electrocardiogram? A repeat electrocardiogram?
6. What percent should have:
   - A. Fasting blood sugar
   - B. BUN
   - C. Enzymes
   - D. Cholesterol/lipids
7. What percent of patients should be in the ICCU?
8. What percent should receive oxygen therapy?
9. What percent should receive anticoagulant therapy?
10. How often should cardiac regulator drugs be used?
11. How often should defibrillation be needed?

11a. How often should closed-chest cardiac massage be needed?

12. Is it important in the clinical management of the infarct patient or in his prognosis that we identify the anatomic site of the infarct?
13. How often should pacemakers be needed?
14. How often should patients stay beyond 30 days with no other coded diagnoses?
15. What is the significance of hypertension on admission? How common is it?
16. How often should we do rectal/pelvic examinations on a patient with acute myocardial infarction at any time during their admission?
17. How often should we do chest Xrays on acute myocardial infarction patients?
18. Are there times you would not like to put a patient in the ICCU? If so, would you monitor such a case on the open wards?
19. What are the indications or contraindications for the use of coronary vasodilator drugs in the patient with acute myocardial infarction? How often should they be used?
20. What are the indications for steroid therapy in acute myocardial infarction patients? How often would we expect them to be used in our hospital?
21. What are the indications for diuretic therapy in acute myocardial infarction patients? How often would we expect them to be used in our hospital?
22. What are the indications for antihypertensive therapy in acute myocardial infarction patients? How often would we expect them to be used in our hospital?
23. What are the indications for antibiotic therapy in acute myocardial infarction patients? How often would we expect them to be used in our hospital?

We never cast our eyes towards "Harrow on the Hill" (let us keep these picturesque denominations of place as long as we can) without thinking of an amiable man and most pleasant wit and physician of Queen Anne's time, who lies buried there—Garth, the author of the *Dispensary*. He was the Whig physician of the men of letters of that day, as Arbuthnot was the Tory: and never were two better men sent to console the ailments of two witty parties, or show them what a nothing party is, compared with the humanity remaining under the quarrels of both.*

*Leigh Hunt, "Garth, Physicians, and Love-Letters," in Men Women and Books, 1847.

PSYCHIATRIC STAFF—Requirements of three year residency training to Board Certified. $26,000 to $36,300 depending upon qualifications. Dramatically beautiful, leisurely paced, cultural, summer and winter vacationland. Superb sailing, skiing, fishing. Resident theater. Near Interlochen National Music Camp. College. J.C.A.H. approved 1,400 bed psychiatric hospital. Three year psychiatric residency program. Excellent fringe benefits. Contact Philip B. Smith, M.D., Room 322, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

PHYSICIAN NEEDED part time for a large scale clinical, epidemiological program. The program starts soon and is to be done in a hospital near downtown Minneapolis. Write: MINNESOTA MEDICINE, 474, 375 Jackson St., St. Paul 55101.

FOR SALE—4 suites of Hamilton examining room furniture, 1 Coleman Photo-electric Colomiter, 1 water bath, 1 Pelton sterilizer and 1 ultraviolet lamp—all at ⅓ cost. Phone 692-2133, E. S. Watson, M.D., Brookings, South Dakota.

GENERAL PRACTITIONER desired for northern Minnesota clinic located near Lake of the Woods area. Enjoy the clean air, clear waters, compatible working arrangements including ample time off for meetings, vacations and good financial arrangements. Excellently equipped hospital (acute, skilled nursing and board and care facilities). Fine clinic one block from hospital. Write: MINNESOTA MEDICINE, 473, 375 Jackson St., St. Paul 55101.

al Wonderland"

Vernon L. Lindberg, M.D.

DECEMBER, 1972

Section 1 of Two Sections

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

Valium®
(diazepam)

To help you manage excessive psychic tension

if skin is infected, or open to infection...

choose the topical that gives your patient–

- broad antibacterial activity against susceptible skin invaders
- low allergenic risk—prompt clinical response

Special Petrolatum Base

Neosporin® Ointment

(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand Polymyxin B Sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical aftercare, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

lk ittle interest in the affairs
in him. His reactions are slow
layed. He speaks very little.
n e does, it's mostly to com-
his insomnia, fatigue, or
t ation.

One way of relieving depression in the geriatric patient is with Tofranil.

Please read the prescribing information for details of usage (lower dosages are recommended for elderly patients and adolescents), precautions, warnings, contraindications, adverse experiences, and dosage recommendations. It is summarized below.

Tofranil® Geigy
imipramine hydrochloride USP

mipramine hydrochloride USP

ications: The concomitant use of this agent amine oxidase inhibiting (M.A.O.I.) com- contraindicated. Hyperpyretic crises or ivulsive seizures may occur. Potentiation of fects can be serious or even fatal. An interval 14 days after M.A.O.I. therapy has been ed should be allowed before this drug may uted. Initial dosage should be low, increases gradual, and the patient's progress should ly observed. The drug is also contraindicated the acute recovery period after myocardial . (b) in patients with known hypersen- the drug. Cross-sensitivity to other dibenz- mpounds should be kept in mind.

nings: *Usage in Pregnancy:* Safe use of ne during pregnancy and lactation has not blished; therefore, in administering the drug nt patients, nursing mothers, or women of ing potential, the potential benefits must be against the possible hazards. Animal repro- tudies have yielded inconclusive results. ve been clinical reports of congenital mal- n associated with the use of this drug, but a lationship has not been confirmed. eme caution should be used when this drug o:

s with cardiovascular disease because of the ility of conduction defects, arrhythmias, rdial infarction, strokes and tachycardia; ts with increased intraocular pressure, history ary retention, or history of narrow-angle ma because of the drug's anticholinergic ties;

hyroid patients or those on thyroid medica- cause of the possibility of cardiovascular y;

ts with a history of seizure disorder because ug has been shown to lower the seizure old;

ts receiving guanethidine or similar agents mipramine may block the pharmacologic of these drugs.

ge in Children: Pending evaluation of results ical trials in children, the drug is not recom- for use in patients under twelve years of age. e the drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as operating an automobile or machinery, the patient should be cautioned accordingly.

Precautions: Because of the possibility of suicide in seriously depressed patients, careful supervision during the early phase of treatment is necessary and hospitalization may be required. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, imipramine may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g. paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential.

Adverse Reactions: *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue), drug fever, cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

How Supplied: Round tablets of 25 and 50 mg.; **triangular** tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration. (B)98-146-850-H (7/71)

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administere intravenously to adults.

In usual IV doses, Lincocin (lincomyc hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in wate But when 4 grams or more per day is given, Lincocin should be diluted in r less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

ifections caused by susceptible strains
pneumococci, streptococci, and
aphylococci, including penicillin-
sistant strains. Staphylococcal strains
sistant to Lincocin (lincomycin
ydrochloride, Upjohn) have been
covered. Before initiating therapy,
alture and susceptibility studies should
performed. Lincocin has proved
luable in treating patients hyper-
nsitive to penicillin or cephalosporins,
nce Lincocin does not share
tigenicity with these compounds.
owever, hypersensitivity reactions
ve been reported, some of these in
tients known to be sensitive to
nicillin.

ell tolerated at infusion site: Lincocin
travenous infusions have not
oduced local irritation or phlebitis,
hen given as recommended. Lincocin
usually well tolerated in patients who
e hypersensitive to other drugs.
evertheless, Lincocin should be used
utiously in patients with asthma or
gnificant allergies.

patients with impaired renal function,
e recommended dose of Lincocin
ould be reduced to 25—30% of
e dose for patients with normal
dney function. Its safety in
egnant patients and in infants
ss than one month of age has
t been established.

incocin may be used with other
timicrobial agents: Since Lincocin
stable over a wide pH range, it is
itable for incorporation in
travenous infusions; it also may be
administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

1972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatme
Skin and mucous membranes—Skin rash urticaria, vaginitis, and rare instances of foliative and vesiculobullous dermatitis h been reported. *Liver*—Although no direct lationship to liver dysfunction is establish jaundice and abnormal liver function te (particularly serum transaminase) have b observed in a few instances. *Cardiovascu*—Instances of hypotension following par teral administration have been report particularly after too rapid IV administ tion. Rare instances of cardiopulmonary rest have been reported after too rapid administration. If 4.0 grams or more adm istered IV, dilute in 500 ml of fluid a administer no faster than 100 ml per ho *Special senses*—Tinnitus and vertigo h been reported occasionally. *Local reacti*—Excellent local tolerance demonstrated intramuscularly administered Lincoc (lincomycin hydrochloride). Reports of p following injection have been infreque Intravenous administration of Lincocin 250 to 500 ml of 5% glucose in distill water or normal saline has produced local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500 m* Capsules—bottles of 24 and 100. *Ster Solution, 300 mg per ml*—2 and 10 ml vi and 2 ml syringe. *Syrup, 250 mg per 5* —60 ml and pint bottles.

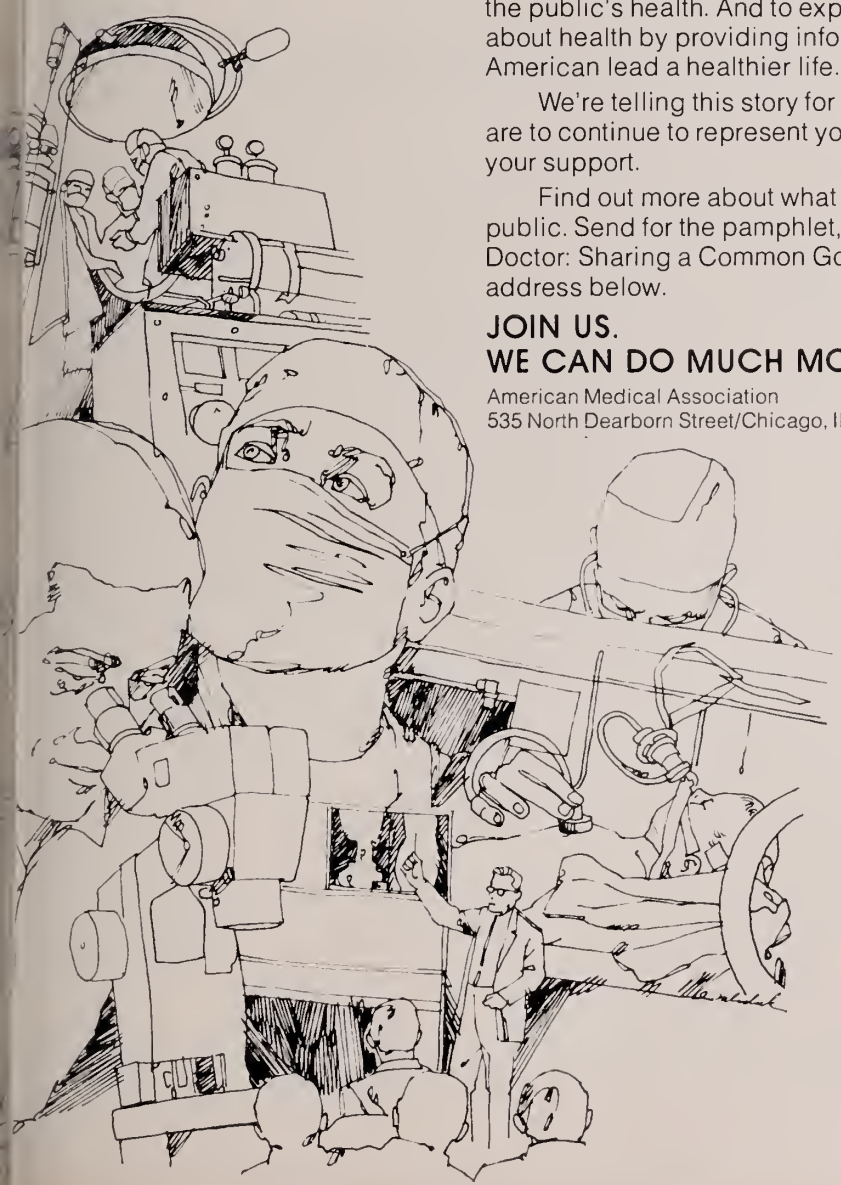
It's about time somebody told the true story of the American Doctor.

You'd agree 100% on that. There have been too many of the other kind of story.

You know that the vast majority of American doctors are honest, hardworking, skilled and dedicated human beings who have the interests of their patients at heart.

That's exactly what the AMA is trying to make the public aware of.

One of the many ways the AMA is doing it is through its special communications program.



Perhaps you've seen pages in newspapers and national magazines signed "America's Doctors of Medicine." They're part of this program. It tells the true story of what it takes to become a doctor. The ways American medicine has improved the public's health. And to express the profession's concern about health by providing information which will help every American lead a healthier life.

We're telling this story for you, the American doctor. If we are to continue to represent you effectively, we need your support.

Find out more about what the AMA does for you and the public. Send for the pamphlet, "The AMA and the American Doctor: Sharing a Common Goal." Write: Dept. DW, at the address below.

JOIN US.
WE CAN DO MUCH MORE TOGETHER.

President's Letter

Christmas Gift

THE FIRST GREETING on Christmas Day in our family is "Christmas Gift," a tradition originating from the Kentucky background of my father. It has come to be a greeting and expression of good will rather than its prosaic meaning, almost as if to say "The Gift of Christmas to you."

During the Advent Season, our schedules are full and often the Gift of Christmas, which in essence can be theistic as well as atheistic, is lost. "Peace on Earth, goodwill towards men" is a goal we should not shun.

It is my hope that our Association can be the originator of many Gifts of Christmas during the coming months through our activities. One way to support this effort would be for dedicated humanitarian physicians to serve on our Association's committees, which are the grass root origins of our policies, dedicated to promoting better medical care for Minnesotans.

Will you join with me in spreading the essence of Christmas? It could help everyone's New Year to be richer.

"Christmas Gift"

George B. Fratten

President
Minnesota State Medical Association

With the means at hand to drastically reduce the number of deaths each year from uterine cancer, we have embarked on a nationwide, life-saving program. Its goal is a Pap test by 1976 for every woman 20 years or older to whom the test is applicable, and for younger women at risk. An ambitious program, doctor, and one which can only be realized with your help.

We are faced with these facts: only 53% of women over 20 have ever had a Pap test; only 20% get a Pap test periodically; each year about 43,000 new cases are diagnosed; this year 12,000 women in this country will die of uterine cancer. And about 75% of these deaths will result from cervical cancer—as you know, almost 100% curable when diagnosed early and treated promptly.

We hope to reach women in the target group not only with the message about the *vital* Pap test, but also with the urgency of including it in the *regular* health checkup. The mortality rate from uterine cancer could thus be dramatically curtailed.

Clearly action is called for. Coordinated action—involving the doctor, the patient, the American Cancer Society—a partnership for life.

a partnership for life

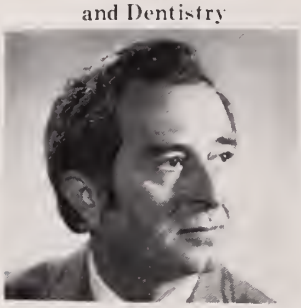
Believe combination drug products are useful.



13.8%
Do not believe combination drug products are useful.

Are combination drug products useful in treatment involving concomitant use of two or more drugs?

Opinion & Dialogue

Doctor of Medicine

Louis Lasagna, M.D.
Professor and Chairman
Department of
Pharmacology & Toxicology
University of Rochester
School of Medicine
and Dentistry

Obviously, many drugs are given concomitantly. Whether it makes sense to combine medications in one preparation, be it capsule, tablet, or liquid, is a question that can be answered only by examining the advantages and disadvantages in the individual case.

Among the advantages is, first of all, convenience. The more medications that are taken concurrently and the more complicated the directions, the less likely the patient is to take medications accurately. From the standpoint of convenience and accuracy, and economy as well, you can make an important case for putting medications together in one preparation, as long as they are compatible.

By the same token, when you prescribe a properly tested and rational combination, you should have less worry about pharmaceutical or pharmacological compatibility — and about reasonable dosage ratios as well. Compatibility of the formulation should be demonstrated in the laboratory and clinic before the product is available for prescription—which is more than can usually be said for the physician's own spontaneous creations. And, the dosage ratios employed in rational precompounded combinations are designed to meet the needs of substantial numbers of "typical" patients.

There is no doubt that many "atypical" patients are to be found, and for them the prefabricated combination must be rejected. But that hardly argues for eliminating rational combinations from the market. Think, for example, of the problems that would arise if the components of widely accepted combinations, like the oral contraceptives and the diuretic-antihypertensives, always had to be prescribed, purchased and ingested separately.

One disadvantage that comes to mind is some doctors' unawareness of the ingredients a given combination contains. For example, a doctor might know that a patient is allergic to aspirin but forget that a certain analgesic mixture, which he knows only by its trade name, contains aspirin. His prescription, then, causes considerable discomfort, to say the least. This problem is a function of physician education, rather than of combination therapy as such. Improving doctors' knowledge about all medicaments they prescribe is a problem that deserves tackling on its own.

Another accusation leveled at combination drugs is that they encourage sloppiness of diagnosis and treatment. In many cases, however, a combination may prove to be the most effective choice. A good example of the usefulness of combinations appears in a recent article in the *Journal of Chronic Diseases* on the efficacy and side effects of an antihypertensive containing three ingredients, in which the track records of the combination drug and the individual ingredients were compared. Interestingly enough, whether the drugs were given individually or together, incidence and severity of side effects were the same. But blood pressure control was invariably better when the drugs were taken in one combination tablet than when they were taken separately (in "titratable" dosage) or in two or three different tablets.

Deciding which combinations constitute rational therapy obviously leads to a discussion of who is to determine which should be used and which should not. Realistically, I think combinations should be evaluated somewhat differently if they are old and established or new and untried.

In today's regulatory atmosphere, there is no possibility of a new combination being put on the market without a substantial amount of acceptable evidence in the form of controlled trials that show it to be safe and efficacious. On the other hand, I believe a different set of standards should apply to combination preparations that have been around for a long time. In other words, physician acceptance over a long period should be given some weight as evidence of the efficacy and safety of these drugs.

The FDA, however, does not seem to share this attitude. It often requires, for these older products, controlled trials that will monopolize the time of already overtired investigators and cost a great deal of money. I wish we could agree on a "grandfather clause" approach to many combinations that have been around for a number of years and that have an apparently satisfactory track record.

For example, I think some of the antibiotic combinations that were withdrawn off the market by the FDA performed quite well. I am thinking particularly of the penicillin - streptomycin combinations that physicians—especially surgical patients—were given by injection. This made for less discomfort for the patient, less demand on nurses' time, and fewer opportunities for dosage errors. To take such a preparation off the market doesn't seem to be good medicine, unless actual overdosage showed a great deal more harm from the injection (rather than the proper use) of the combination.

The point that should be emphasized is that there are both rational and irrational combinations. The real question is, who should determine which is which? Obviously, the FDA must play a major role in assessing this determination. In fact, I don't think it can avoid taking the ultimate responsibility, but it should enlist the help of outside physicians and experts in assessing the evidence and in making the ultimate decision.

Maker of Medicine

. Clarke Wescoe, M.D.
President
inthrop Laboratories

two medications are
l effectively to treat a

he other semantic ploy
n called into play is to
cribe a combination
duct as rational or irra-
nal.
ake antibiotic mixtures,
source of much of the
icism generated against
combinations generally. Obviously, no one should be exposed willy-nilly to the potential side effects of two or three antihiotics when only one is needed. At the same time there are cases where it is prudent to prescribe more than one. The clinician is the judge in these circumstances, as he should be.

There is no clear definition of the word rational. Most persons, I suppose, would find it synonymous with reasonahle, hut in many circumstances it may best be defined as the opinion of those in power at the moment.

Other factors govern combination therapy, not the least of which has heen its broad use by practicing physicians anxious to achieve convenience in prescribing, to reduce medication error, and to save money for their patients. Combinations clearly have met the test on all three counts.

I have been impressed hy studies showing that the rate of error climhs markedly with the numher of medications to be taken, even with sophisticated patients. When medically justified, therefore, this factor alone supports the logic of comhination therapy.

The cost argument for combinations appears to be irrefutahle. In 1971, R. A. Gosselin studied the 71 combination products (excluding oral contraceptives) among the 200 most prescribed drugs. The study found that if all 71 products were discontinued, and if each ingredient in these combinations were prescribed separately, the price of medicines to patients would jump by $443.2 million on a national basis! At a time when the cost of medical care is under so much fire, it would be nonsensical to boost costs without clearly irrefutable medical reasons.

The part played by government on this question, of course, is fundamental. The FDA should play a role in determining which comhinations are reasonable. That role, as defined by law and regulation, is to ensure that any medication on the market is safe and effective in line with its label claims. Certainly combinations are entitled to as much consideration as single entities—neither more nor less. So long as the addition of one drug to another does not make either less safe, or less effective, so long as they are compatihle in a formulation, we have a reasonable product. It makes no sense to recommend the use of two products for certain conditions and to deny their being combined in a single form. An unhappy side effect of the prohlem concerns the efficacy panel discussions of many products submitted for review. The term "effective, but" has been freely interpreted to mean "ineffective" in toto, regardless of the merit of the individual drugs. This interpretation has placed numerous useful comhination products in needless jeopardy.

In reading the actual reports of the review panels, it seems clear that some of the ratings were based less on scientific research and clinical observation than on the "informed" opinions of the panelists. These "informed" opinions were accepted at face value, while the "informed" opinions of others who had used the products were rejected. All of this put combination products into a sort of scientific never-never land.

It should be kept in mind hy all, government as well as others involved in our health care system, that advances in therapy are seldom made in leaps and hounds hut rather by small painstaking steps—and that some of these steps have resulted from research in combination drugs as well as with single entities. Given the near-infinite biologic variation in patient response, this is hardly surprising to clinicians. It should not be to regulatory agencies either.

In the end, the practicing physician is in the best position to decide if a particular comhination makes sense. Such a decision should not he made exclusively by those whose responsihility for continuing clinical care is limited. Clinicians are the best judges of efficacy because the ultimate proof of any product's effectiveness is acceptance by phvsicians who have observed its actions in patients over time. The corollary statement may be made about over-the-counter medicines, which would not long survive if they failed to afford the relief the user anticipates. That the antihistamine in a "cold" remedy may not *always* be necessary is no reason to proscribe the combination generally.

Toxic Epidermal Necrolysis (Scalded Skin Syndrome)

Associated with Staphylococci

KRISHNA M. SAXENA, M.D. AND A.S. SETHI, M.D.

TOXIC EPIDERMAL necrolysis (scalded skin syndrome) as a separate entity was first described by Lang and Walker[1] and Lyell[2] in 1956. The association with staphylococcal infection has been well documented by the recent work of Melish and Glasgow.[3,4]

Our recent observation of six cases in two years suggests that the condition may be more common than the reports listed in the literature indicate. The disease usually starts as a tender skin lesion preceded or followed by marked erythema resembling scalded skin. Separation of the epidermis by slight pressure (Nikolsky sign) appears as a characteristic feature of the syndrome in the next 48 hours. Desquamation of the skin in large sheets follows, leaving wet raw areas which heal without scar formation. A purulent conjunctivitis is often present.

Thirteen cases of 'scalded skin syndrome' have been seen at the Children's Hospital during the last six years, six of them in the last two years. There were 10 females and three males between 14 days to three and a half years of age (Table 1). Seven children were younger than six months, four less than one month of age. All but three cases had some preceding infection, eight cutaneous, one otitis media and two upper respiratory. No patient had a history of drug ingestion prior to the illness.

The distribution of lesions is illustrated in Table 2. The face was the commonest site of involvement. Bullae were seen in six cases. Nikolsky's sign was positive in all cases. Fever was present in 11 patients, three of whom were also 'toxic.' Six children had purulent conjunctivitis. No other mucosal lesions were seen. Leucocytosis occurred in eight patients.

All were treated with antibiotics for staphylococcal infection. In one child, improvement was evident before the start of antibiotic therapy. Complete recovery occurred in all children. The illness lasted from five to 20 days. The mean duration was 10.5 days.

Coagulase positive staphylococci were cultured from the skin in 11 of the 13 cases. In nine of these patients the organism was also cultured from other sites usually the throat (Table 3). Coagu-

12.	12 months	M	10 days	Nil
13.	20 months	F	8 days	Pustular skin lesion, rhinorrhea

lase positive staphylococci were cultured from the eyes in three cases, and stools in two. Phage-typing was possible in only four of the recent cases. All showed group II staphylococci of phage types 55/71/3C/3A/53.* The same phage types were seen in cultures obtained from different sites in Cases 10, 11, 12 and 13.

Summary of two representative cases is briefly presented.

Case Reports

Case 11

A six-month-old female was admitted on August, 1970. Her illness had started with redness around the eyes, proceeding to a conjunctivitis by the next morning. On the third day of the illness, erythema was also seen around the mouth, the nose and neck. On the fourth day, a markedly tender erythema was present all over the face, arms, trunk and legs up to the knees. On the same day, desquamation was seen on the forehead. By the nex day, desquamation was widespread and Nikolsky sig was positive. Peeling of the skin was more evident in th axillae, the neck and around the mouth. The skin aroun the mouth had the pursestring-like appearance char acteristic of this syndrome (Figures 1 and 2). Throughou this time, the child was febrile with a temperature o 37.8°C to 38.4°C. About the eighth day of illness heal ing was evident, the Nikolsky Sign became negative an the fever disappeared. No leucocytosis was seen durin the illness. Her IgG level was 120 mg% (normal for he is 200-660 mg%). Her IgM level was normal. Serun albumin and electrolytes were normal.

Coagulase positive staphylococci—group II—phag 79/3C/71/53 were cultured from her skin from thre different sites—ear, axillae and neck. Similar phage type were also cultured from the throat and stool, but blood culture was negative. One of her siblings who had scalp lesions also grew the same coagulase positive phag 79/3C/71/53 staphylococci.

Treatment was begun with saline soaks and I.V. Methicillin in a dose of 200 mg/kg/day. Later oral oxacillin was substituted for the antistaphylococcal antibiotic treatment which was continued for a total of nine days.

*Phage typing was kindly done by Dr. Adnan Dajani, University of Minnesota.

omplete healing of the conjunctivitis and skin lesions ccurred within 10 days.

ase 12

A one-year-old male child was admitted with a history f generalized erythema with desquamation, fever and ritability of two days duration. The illness started with eri-oral redness which soon progressed to tender ery- hema of the whole trunk, associated with fever of 39.6°C.

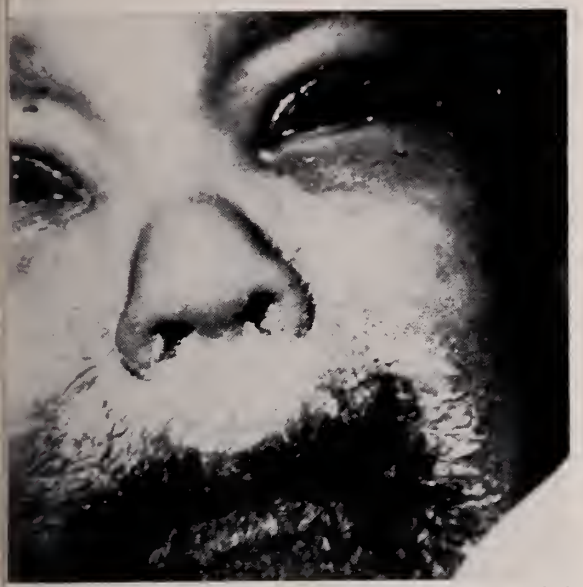

Fig. 1—Note the flaking, crusting lesions and denuded issures around the mouth. Purulent conjunctivitis was lso present in this child.

Fig. 2—Lesions around the mouth in Scalded Skin Syndrome.

There was no preceding lesion or history of drug ingestion. Purulent conjunctivitis was evident on the day of admission. On the second day, desquamation was seen on the face and neck, with associated flaccid bullae on the face and back. Erythema spread to the thighs on the second day. The child continued to be febrile and irritable, but could feed well. On the third day, desquamation was seen in the axillae, arms, face and neck. Denuded areas appeared with peeling of the skin and Nikolsky Sign was strongly positive.

Laboratory investigations revealed a hemoglobin of 13 gm%; the total leucocyte count was 19,400/cu.mm. with neutrophils 50%, lymphocytes 46%, monocytes 2% and eosinophils 2%. Urinalysis was normal. Cultures from the right ear, both eyes, nasopharynx and skin grew coagulase positive staphylococci (group II, phage type 3A/3C/55/71).

Blood and spinal fluid cultures were negative. Quantitative estimation of immunoglobulins showed normal IgG and IgM but the IgA level was low, 25 mg% versus an expected normal value between 46-400 mg%.

Therapy was started on the day of admission with saline soaks to the skin and frequent eye and mouth washes. Fluids were given orally in a volume of 2400 ml/m^2/day. Methicillin 200 mg/kg/day was given intravenously and later changed to oxacillin orally for a total duration of 10 days. Improvement was noted within a day and on the third day of admission, (fifth day after onset), he became afebrile. By this time, his skin had started healing and the Nikolsky Sign had become negative. Complete healing occurred in eight days.

Discussion

The exact incidence of 'scalded skin syndrome' associated with staphylococcal infection is not known. Constantino et al.[5] reported three cases, two due to staphylococci and collected 10 from the American literature. Tyson and colleagues[6] reported three cases, two due to staphylococci. Lowney et al.[7] reported 10 cases, two associated with coagulase positive staphylococci. Lyell, Dick and Alexander[8] reported six cases due to coagulase positive staphylococci and Melish and Glasgow[4] discuss 28 cases.

Clinical Manifestations

The clinical manifestations vary and include at least three principal modes of presentation.

Exfoliating Dermatitis

The most common picture is of a child who has a rather abrupt onset of widespread erythema, marked tenderness of the skin with a dry, coarse, "sandpaper" texture. This is soon followed by separation of the epidermis so that after light stroking, the epidermis becomes wrinkled, producing a positive Nikolsky Sign (Figure 3). Flaccid bullae then form followed by separation of

Fig. 3—Positive Nikolsky sign and pustular lesions on the abdomen.

Fig. 4—Peeling of skin in large sheets.

Fig. 5—Note the lesions around the mouth and face. Desquamated lesions were also present on the neck and shoulders. The right anticubital fossa has a denuded, red moist area due to peeling of the skin.

large sheets of the epidermis leaving moist re raw areas behind (Figure 4). These areas dry i about two days. Thick dry flakes appear on thes areas, characteristically around the mouth. Th thick yellowish dry patches separated by red de nuded fissures around the mouth form a charac teristic appearance which was present in all ou cases (Figure 5).

Complete healing without scar formation us ually occurs in eight to 10 days.

Scarlatiniform Rash

The second picture is a generalized scarlatini form erythema, "sandpaper" skin texture and dif fuse tenderness of the skin. In the next two t three days, the erythematous areas become dry thickened and cracked and the skin desquamate in large dry flakes especially around the mouth In the early stages and the final desquamativ stages, the first and second presentations are alike However, this picture is characterized by the ab sence of the intermediate stages of bullae forma tion and widespread exfoliation. This can be dif ferentiated from Streptococcal Scarlet fever by th absence of 'Strawberry tongue,' enantham or posi tive streptococcal culture.

Bullous Impetigo

The third mode of presentation, usually in the newborns is localized bullous impetigo. The same phage group II staphylococci are seen in these pa tients. None of our patients belonged to this group.

Other Presentations

A purulent staphylococcal conjunctivitis ap peared in the eary stages in approximately half of our patients and in several of the patients of Melish and Glasgow.[3,4] The syndrome may be preceded by impetigo or a secondarily infected skin. We observed infection of the throat and nose preceding the syndrome in half of our cases.

The course of the disease is variable. Although it may be fatal in the newborn infant, with proper fluid and electrolyte therapy, the prognosis is good. In the majority of cases, the recovery is complete within one to two weeks. Mortality rate of 0-7% has been recorded between one and five years of age, in contrast to an overall mortality of 23-30%.[7,9-12] The mortality is usually due to secondary infections and loss of fluids, protcins and electrolytes from the denuded areas. All our patients survived with complete healing within one to two weeks.

Pathology

The primary pathological lesion is epidermal necrosis with intra epidermal split at the level of the stratum granulosum. Occasionally, detachment of the epidermis at the dermal-epidermal junction is seen. No inflammatory reaction occurs in either the epidermis or the dermis. Many investigators have reported an association of the entity with group II staphylococci especially with phage type 71 staphylococci.[6-8,10,13-16] The work of Melish and Glasgow[3,4] has given a conclusive proof to this association. They found association of group II coagulase-positive staphylococci in all the 28 children presenting with the scalded skin syndrome. The staphylococci isolated from these patients produced exfoliation in newborn mice. Typical skin reaction was produced in mice by intraperitoneal injection of these organisms, whereas, staphylococci belonging to phage type other than group II failed to evoke a similar reaction. The lesions progressed from the development of a Nikolsky Sign to bullous formation and exfoliation. The staphylococci could be recovered from the involved animals, thus fulfilling Koch's postulates. The clinical picture, sterile bullae and lack of inflammatory reaction in epidermis or dermis suggests that the skin reaction is due to some soluble substance produced by group II staphylococci. This is supported by the experimental observations of Melish and Glasgow[3] that focal intraperitoneal inoculation of group II staphylococci in newborn mice evoked generalized widespread skin reaction typical of scalded skin syndrome. In nine of our patients, coagulase positive staphylococci were cultured from multiple sites including the throat in seven. Staphylococci were also cultured from the eyes in three of the six children in whom cultures from the eyes were obtained. These observations strongly suggest that the eyes and nasopharynx could be the source of infection at least in some patients. It seems very likely, therefore, that staphylococci group II produce some substance which disseminated from a focal site of infection to produce widespread dermal erythema, tenderness, bullae and exfoliation.

Several 'toxins' formed by group II staphylococci have been studied. The substance or toxin related to scalded skin syndrome has been found by Melish, Glasgow and Turner[17] to be a macromolecular ampholyte with some characteristics of delta hemolysin. It was found to be distinct from alpha and delta toxins by Kapral and Miller[18] who named the factor "Exfoliatin" because of its epidermal splitting activity. Arbuthnott, et al.[19] have also confirmed the presence of a separate "epidermolytic toxin" which is distinct and separate from hemolysin.

Therapy

A vigorous supportive care similar to burn therapy is necessary since fluid, electrolyte and protein loss from the denuded skin may be quite marked. Repeated evaluation of the level of hydration, electrolytes and proteins is mandatory so that necessary replacements may be made. Most of our patients could maintain an adequate oral intake in spite of severe lesions around the mouth and on other parts of the skin. Skin care includes isolation to avoid secondary infection and normal saline soakings. Eyes and oral mucosa need repeated washing.

After obtaining appropriate cultures from skin, eyes, pharynx and blood, the children should be given antistaphylococcal therapy. We have used methicillin in doses of 200 mg/kg/day I.V. initially. This is changed to oral oxacillin after clinical improvement is apparent. Steroid therapy has been advocated by some authors (Constantino, et al.)[5] and condemned by others (Melish and Glasgow).[4] Considering the association of the condition with staphylococci, we feel quite strongly that steroids have no place in the therapy of these patients.

Summary

Thirteen cases of toxic epidermal necrolysis are presented. Eleven of the 13 cases were associated with coagulase positive staphylococci. Phage typing was done in four and it revealed group II phage types 55 and 71. The disease may manifest as exfoliating dermatitis, scarlatiniform rash or bullous impetigo. Conjunctivitis is often present. Staphylococci were cultured from the nasopharynx in seven of our cases. All the patients recovered without sequelae. The syndrome is most likely caused by a specific exfoliative toxin liberated by group II staphylococci.

Acknowledgments

We are grateful to Dr. Adnan Dajani, University of Minnesota, for doing phage typing.

Before the Doctor Arrives

ARTHUR F. GIERE, Ph.D., D.JUR.

IN THE YEAR 1891, a medical doctor named Fredrik Mohn, published a book in the Norwegian language, entitled, "Before The Doctor Arrives," which contained much information about medical aids and health directions. This book was printed in Decorah, Iowa, and contained 151 pages.

This volume is very interesting since it recorded the thinking of the medical profession which existed 79 years ago. It is also a noteworthy item of Norwegian-American history. Here is a free translation of some of the interesting bits of the medical specifications and health regulations designated in this book. The Physician writes:

"When ought a man to marry? It would be best when he is one or two years older than the girl.

"Never visit a sick person when you have an empty stomach. That is a rule which never must be violated.

"When a sick person dies the body must be immediately placed in a coffin which has been tarred on the inside and made airtight and then it must be promptly removed from the room.

"Women must get rid of their corsets, because so many illnesses are caused by the use of corsets. The circulation of the blood is stifled and numerous women have become weak and unhealthy. So, for God's sake throw away the corsets.

"Whom should a Norwegian marry? I would recommend that all Norwegians marry people o German extraction. The dyspeptic Americans and the flat bosomed American women and all maidens who are so dumb that they want to act like the Yankees, in this matter, are not very attractive nor desirable as mates, so it should not be necessary to advise people not to get married to any of them.

"Women's under pants should always be of wool and should reach to the ankles instead of only to the knees and in the wintertime, all women ought to wear two pairs of pants, both reaching to the ankles.

"What should one do to reduce weight? Fat people who wish to become lean should never eat more than five ounces of meat or fish for breakfast together with a large cup of tea, without sugar or milk, and an ounce of bread and a soft boiled egg. For the noon meal, one may eat six ounces of any kind of fish or meat, except herring or pork or veal. One should eat greens, but no potatoes, nor beets nor carrots. One can have one ounce of dry toast, some fruit pudding and a glass of wine. Champagne, beer or port are, strictly, forbidden. For the evening meal, three or four ounces of the above named fish or meat and a small cup of tea with toast and three ounces of fruit. All fat persons should have physical exercises and take daily walks."

Mr. Giere is a country lawyer practicing in Galesville, Wisconsin.

Spontaneous Cholesterol Embolic Renal Failure

MICHAEL G. BLOOM, M.D., LORING H. WINTHROP, M.D., AND GEORGE A. SAROSI, M.D.

RAPIDLY PROGRESSIVE RENAL failure in the elderly is a common and extremely serious medical event. When renal failure is complicated by the rapid onset of hypertension with oliguria or anuria, the diagnosis of cholesterol embolization to the kidneys should strongly be entertained.[1-8]

Case Reports

Case 1

A 72-year-old male was well until December 21, 1967 when he underwent surgery for a ruptured abdominal aortic aneurysm below the renal arteries. Both common iliac arteries were involved in the aneurysm. A Y-shaped Dacron graft was inserted. The resected specimen contained many cholesterol crystals. Postoperatively, the femoral pulses were strong and the urine output was adequate, but the blood urea nitrogen rose from 26 mg% preoperatively to 81 mg% on the fifth day. Intravenous pyelogram showed good excretion in a normal left collecting system, but only a nephrogram on the right. Cystoscopy and a right retrograde pyelogram were normal. The blood urea nitrogen subsequently fell to 25 mg% by the time of discharge from the hospital.

He was again hospitalized in 1970 for transient cerebral ischemic attacks. Electroencephalogram, lumbar puncture and brain scan were normal. He was treated with oral anticoagulants and was discharged much improved.

The third admission, for congestive heart failure, came in May 1971. He responded rapidly to digitalis and diuretics. His blood urea nitrogen was 41 mg%, creatinine clearance 33.5 cc/minute and a urine culture was negative.

His final admission was in July, 1971 when he developed thrombophlebitis of the right calf and popliteal area. The blood pressure was 200/120; and fresh flame-shaped hemorrhages were noted in both fundi. In addi-

Fig. 1—(Patient No. 1) Abdominal aorta. Atheromatous plaque showing cholesterol crystals. (Hematoxylin and eosin; original magnification x 100).

tion he had moist rales at both bases posteriorly, an S_3 gallop and left ventricular heave. Admission blood urea nitrogen was 63 mg%; chest film revealed mild congestive heart failure and left ventricular prominence. Electrocardiogram revealed an old anterior myocardial infarction.

Hospital Course: Parenteral administration of α-methyl Dopa was begun with a prompt drop of the blood pressure to 110/80. The patient did well until July 24 when he left the hospital on a weekend pass. He returned feeling worse with a weight gain of 2.7 Kg. By the next morning, he developed chills, fever, diarrhea and mental confusion. Medications were stopped. Two days later, the blood urea nitrogen rose to 85 mg%, the serum creatinine to 9.5 mg%. Urine culture grew Klebsiella; gentamycin was started in doses appropriate to the serum creatinine. On July 26, blotchy livedo reticularis and petechiae appeared from the lower abdomen down to the feet. Simultaneously urine output dropped from 400 cc/day on July 26 to 140 cc/day on July 30, in spite of adequate blood pressure and large dose of intravenous furosemide. The livedo reticularis and petechiae waxed and waned for the next two days. Repeated blood cultures were negative. Biopsy of several petechial lesions failed to show either bacterial clumps or cholesterol clefts. On August 2, a left retrograde pyelogram showed no obstruction. A translumbar aortogram showed intact renal arteries and poor renograms. On August 4 and August 5, the patient underwent hemodialysis for four hours each day. The blood urea nitrogen dropped to 66 mg% and the serum creatinine to 6.9 mg%. His sensorium deteriorated and the livedo reticularis of the lower extremities worsened. Urine output declined and the blood urea nitrogen rose to 171 mg%. The patient died on August 25.

Autopsy: The prosthetic abdominal aortic graft was in good condition, but there was aneurysmal dilatation of the aorta above the graft. Microscopic sections of the aorta showed severe atherosclerotic destruction and mural thrombosis. Most of the thrombi were old and hyalinized and contained innumerable empty, cholesterol crystal clefts with no inflammatory reaction. Both kidneys showed varying degrees of tubular atrophy in wedge-shaped areas. There was only mild to moderate arteriosclerosis of the renal arteries but there were multiple clusters of empty cholesterol crystal spaces, usually surrounded by multi-nucleated giant cells and a small amount of loose connective tissue occluding the vessels. The atrophic cortical areas did not suggest old necrotic infarcts but appeared to be the result of a slower atrophic process (Figures 1 and 2).

Occlusion of medium sized arterial branches by cholesterol emboli were also found in the spleen, adrenals, pancreas, testis and vertebral bone marrow.

Case 2

A 79-year-old white male entered the hospital on June 29, 1971 because of symptoms of congestive heart failure. Physical examination revealed an oriented, mentally competent, elderly male in no acute distress. Pulse was 100, the blood pressure 170/105. The neck veins were distended at 60° elevation and basilar moist rales were audible posteriorly. The cardiac rhythm was regular and an S_4 gallop was present. There were multiple surgical scars on the abdomen and the liver was palpable 2 cm below the right costal margin. There were no abdominal bruits. Pitting edema was present in both lower extremities to the knees.

The past history included a sigmoid colectomy for diverticulitis, a partial gastrectomy for chronic peptic ulcer disease and a cholecystectomy. In 1965 he had a transurethral resection of the prostate for benign prostatic hypertrophy. In 1966 he was treated for a urinary tract infection, after which his blood urea nitrogen was 18 mg%, the serum creatinine 1.3 mg%. The blood urea nitrogen in April, 1971 was 20 mg%, rising to 32 mg% later that month. Urinalysis and culture were negative at that time. Intravenous pyelogram showed both kidneys to be 10 cm long; the left kidney showed poor function

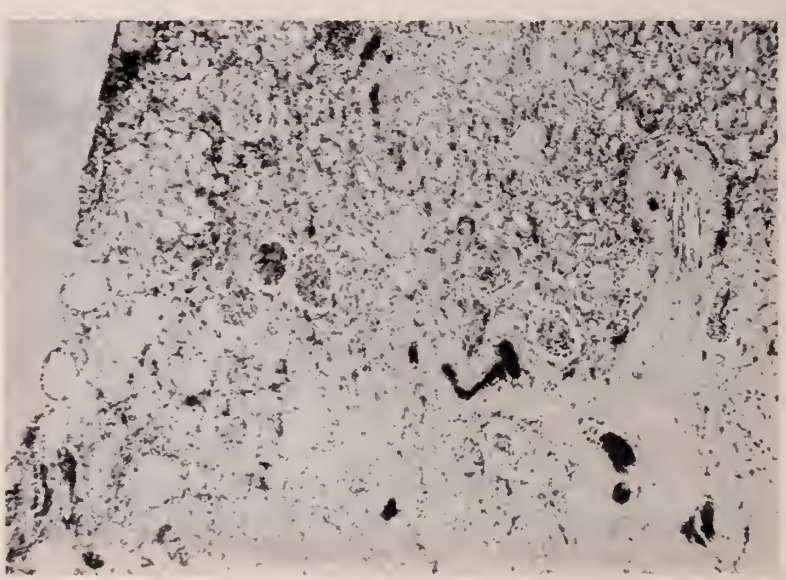

Fig. 2—(Patient No. 1.) Renal cortex. Cholesterol crystals in an arteriole with adjacent parenchymal atrophy. (Hematoxylin and eosin; original magnification x 450).

and the collecting system did not visualize well.

On admission (June, 1971) the blood urea nitrogen was 33 mg%, the serum creatinine 3.7 mg%; urinalysis showed 21-30 white blood cells per high power field, 1+ proteinuria, and no casts. Urine culture grew greater than 10^6 colonies of Enterococcus. The chest film revealed mild congestive heart failure. Electrocardiogram showed left axis deviation and an old anteroseptal myocardial infarction. The patient was treated with digitalis and diuretics and he improved rapidly. On July 6 he had a sudden rise of temperature to 105° F. and became obtunded. The blood urea nitrogen was 51 mg%, the serum creatinine 5.2 mg%. Urine culture again grew greater than 10^6 Enterococci. Blood, cerebrospinal fluid and sputum cultures revealed no growth. Urine output fell to 150 cc/24 hours. Cerebral echogram showed a 1-2 mm shift of the pineal from left to right. Brain scan showed increased activity over the left convexity, possibly consistent with infarction or other early injury in the left Sylvian area. Repeat lumbar puncture, brain scan and electroencephalogram were not diagnostic. He remained comatose for the next four days, while the fever declined gradually. Urine cultures then revealed no growth. Over the next ten days, his sensorium slowly cleared and the urine output increased temporarily. In spite of urine output in excess of 1000 cc/24 hours, the azotemia worsened, the patient again became comatose and expired on August 26, 1971. The last blood urea nitrogen was 110 mg% and his urine output for the last 24 hours was 225 cc.

Autopsy: Bilateral bronchopneumonia and severe atherosclerosis of the aorta with some "egg shell" calcification and ulcerations of the intima were found. Microscopically, many of the mural thrombi were extensively hyalinized and many of these contained innumerable empty cholesteral crystal clefts without inflammatory reaction. Examination of the kidneys revealed no evidence of active pyelonephritis and there was only moderate arteriosclerosis of large and medium sized arteries. The striking finding was the occlusion of many medium sized and small renal arteries by clumps of cholesterol crystals. These occluded vessels were related to wedge-shaped areas of renal tubular atrophy in the adjacent cortex. Similar small artery cholesterol emboli were found in sections of the spleen, pancreas, testes and in the small mucosal arteries of the small intestine.

Discussion

Clinical Setting and Pathogenesis

Atheromatous emboli occur in two principal forms, the first is the so-called atheroembolus. This form of embolization occurs when large plaques are dislodged from their origin and occlude major arterial branches downstream. Recognition of this problem is seldom difficult because of the very dramatic and often catastrophic nature of the embolic event. The second form, the so-called cholesterol embolus is subtle and difficult to recognize. Cholesterol emboli occur when cholesterol crystals and other atheromatous components are released or dislodged from erosions of atheromatous plaques.

The embolized particles are microscopic in size, and unless the occlusion involves strategically important blood vessels, the entire event may remain silent.

The usual clinical setting of cholesterol embolization is a procedure involving the abdominal aorta. Thus embolization is frequently preceded by aortography with contrast studies. The relatively stiff catheter is often lodged into an area of erosion on an atheromatous plaque, and the injection of contrast material under high pressure may produce showers of emboli downstream from the diseased area.[9] Surgical manipulation of a diseased aorta, especially at the time of replacement of an abdominal aortic aneurysm with a prosthetic graft may easily fragment atheromatous plaques and cause emboli.[3,10] In this latter setting, due to the proximity of the renal arteries to the operative field, the kidneys often become the site of cholesterol embolization which may lead in the immediate postoperative period to anuria or oliguria.

Cholesterol emboli may also occur spontaneously, most likely from bleeding into an eroded atheromatous plaque with dislodgement of cholesterol crystals.[5,6]

Although the abdominal aorta is perhaps the most common source of cholesterol emboli, other vessels have been noted to give rise to similar events, especially the ascending aorta in syphilitic patients, the coronaries, and the proximal internal carotids.[2,11]

Pathology

The lodgement of cholesterol emboli are seen as long needle-like slits in the medium and small arteries (150-200 μ in diameter),[5] which stimulate a foreign body giant cell reaction. Following the initial insult, fibroblasts proliferate about the crystals and the giant cells disappear after a variable period of time. The vessels may then recanalize, re-establishing some patency to the lumen. The end result of this process is a fibrosing endarteritis with marked reduction in the caliber of the blood vessels.[2,4,5,12]

Renal Involvement

The kidney is the organ most frequently involved in this process. The fibrosing endarteritis occurs in the smaller renal vessels causing tissue ischemia distal to the occlusion. This in turn leads

to dysfunction, atrophy and rarely to necrosis. In the kidney the majority of the ischemic changes are seen in the renal cortex, and the extent of renal damage is well correlated with the magnitude of the occlusive process. The occlusive lesions are frequently found at bifurcations of arteries. Arcuate, intralobular, and terminal arteries are most frequently affected. Multiple occlusions can account for the patchy ischemic degeneration of the renal cortices. Spotty cortical atrophy, usually wedge-shaped is the major finding. The wedge-shaped zones of ischemia are interspersed between relatively normal renal tissue, and frank necrosis is rarely found.[2,6,7,13] The hypertension that often follows cholesterol emboli to the kidneys is most likely mediated through the renin-angiotensin-aldosterone mechanism.[2,10] The location of the emboli proximal to the juxtaglomerular apparatus further adds validity to this theory.[10] The hypertension can be a new finding with an abrupt rise of previously normal blood pressure or on occasion, intensification of existing moderate hypertension.[4,6,7,9,12]

The other major renal complication of cholesterol emboli is renal failure which may manifest itself as acute oliguria or anuria. Rarely, urine output remains normal in the face of rising creatinine.[3,4,7,10] The renal failure occasionally occurs in a step-wise progressive fashion temporally related to episodes of showerlike embolization.[4,7]

Clinical Manifestations

The usual manifestations of cholesterol embolization will largely depend on the site and extent of the embolic process. Frequently, there are no readily recognizable signs or symptoms because of the spotty involvement of the affected organ and because of the presence of adequate collateral circulation. Since the abdominal aorta is the usual site of origin for these cholesterol emboli, the abdominal viscera are most frequently involved. The kidney, pancreas and spleen are the organs most frequently involved.[2,10,14]

In addition to visceral involvement, cholesterol embolization may be manifest by ischemic changes of the lower extremities with pain, livedo reticularis, cyanosis, and gangrene despite adequate arterial pulses, showers of petechiae on the lower extremities and abdominal wall and subcutaneous nodules.[12] Occasionally, abdominal pain, gastrointestinal hemorrhage and pancreatitis may overshadow these complaints.[2,4,6,15] When the source of the cholesterol emboli is in the ascending aorta, especially in an aorta diseased by syphilis, the main findings may be neurological, with transient blindness due to embolization to the retinal vessels and/or various cardiovascular complications.[2,11]

The clinical diagnosis is difficult in these patients. There are no distinguishing characteristics of this form of oliguric renal failure from any other in the older age group. Examination of the urinary sediment is nonspecific; there is modest proteinuria, and a slight increase in red and white blood cells, with occasional hyaline and granular casts.

The definitive diagnosis of cholesterol emboli can only be made after histopathologic examination of involved tissues confirms the presence of cholesterol clefts. In the first patient, the diagnosis was suspected because of the recurrent showers of petechiae in the presence of rapidly progressing hypertension; however, the histopathologic examination of one of the excised petechiae failed to show the expected cholesterol crystals. In the second patient the diagnosis was not considered antemortem.

In the clinical setting of rapidly advancing hypertension with or without oliguric renal failure every effort should be made to establish the correct etiologic diagnosis. Separation of cholesterol embolization from other clinically similar conditions is important in that the various forms of vasculidities, such as polyarteritis nodosa or subacute bacterial endocarditis may be treated with specific therapy, while cholesterol emboli at the present time may be treated symptomatically only.

It is of further interest to note that the first patient was on long-term oral anticoagulant therapy for transient ischemic attacks just prior to the clinical onset of cholesterol embolization. Moldveen-Gerominus and Merriam pointed out that anticoagulation may enhance cholesterol embolization by preventing adequate thrombus formation over an eroded atheromatous plaque.[14]

Bilateral Hip Arthroplasty after Renal Transplantation

Total Rehabilitation of the Patient

JOHN E. WOODS, M.D., FRANKLIN H. SIM, M.D., CARL F. ANDERSON, M.D. AND WILLIAM J. JOHNSON, M.D.

RENAL TRANSPLANTATION has now moved from the realm of the experimental into that of practical therapeutics. Experience at the Mayo Clinic with more than 120 renal allografts shows a rate of rehabilitation with successful transplants of 90% or higher, despite the fact that transplantation is being offered to patients previously excluded as extremely high risks. In the following case the details of total rehabilitation in a patient with the double handicap of end-stage renal disease and bilateral avascular hip necrosis are reported.

Report of Case

A 37-year-old man was first seen at the Mayo Clinic on Jan. 13, 1969, with end-stage renal disease. In 1953 he had been rejected for military service because of proteinuria. He felt well, however, until gross hematuria occurred in 1958. At this time, a diagnosis of chronic nephritis was made and a protein-restricted diet was begun. He did well on this regimen until June 1968, when numbness developed in the toes of both feet and paresthesias developed in the first three digits of both hands. Because of increasing renal failure and hypertension, the dietary intake was reduced to 18 gm of high biological value protein and 40 mEq sodium and treatment with alpha methyldopa was started. Although the neurologic symptoms abated somewhat, the patient was referred by his family physician to the Mayo Clinic to be considered for renal transplantation.

Physical Examination

On physical examination, the blood pressure was 160 mm Hg systolic and 100 mm Hg diastolic. Uremic fetor was present. In the upper extremities, vibratory sensation was decreased. In the lower extremities deep tendon reflexes were hypoactive and associated with hyperesthesia of the soles, moderate decrease in vibratory sensation, and moderate pretibial edema.

Laboratory Studies

Laboratory studies included urinalysis with specific gravity of 1.005, pH—6.2, sugar—negative, and protein —grade 2; microscopic examination showed leukocytes, grade 1, with occasional hyaline and granular casts. The leukocyte count was 9,400 and the hematocrit reading was 34%. The value for serum creatinine was 18.8 mg/100 ml, for calcium, 8.7 mg/100 ml, and for phosphorus, 10.2 mg/100 ml.

Urologic and Psychiatric Evaluations

Urologic and psychiatric evaluations did not reveal contraindication to surgery. After an appropriate evaluation and tissue typing, the patient's sister was accepted as a kidney donor. Accordingly, on January 29, 1969, bilateral nephrectomy and renal transplantation were accomplished without incident. Pathologic examination of the patient's kidneys revealed chronic glomerulonephritis. The serum creatinine fell from a preoperative value of 20.5 mg/100 ml to 1.1 mg 11 days later.

The patient was dismissed from the hospital in February, 1969. Ten days later his serum creatinine measured 2.75 mg/100 ml and the amount of prednisone was increased from 50 mg/day to 100 mg daily for several days and maintenance therapy with azathioprine (Imuran) (2 mg/kg) was continued with a resultant gradual return of serum creatinine to the previous normal level. Oral doses of prednisone were gradually reduced over the subsequent months to a level of 20 mg daily by October 27, 1969.

Two months later the patient complained of pain in both hips and roentgenograms revealed evidence of bilateral avascular necrosis. Nonweight-bearing crutch-walking was instituted and the patient remained ambulatory and active for several months, spending long hours driving a tractor without major problems. Follow-up roentgenograms, however, revealed evidence of continued progression of hip necrosis, so that by January, bilateral total hip arthroplasty was deemed necessary. Renal function continued at normal levels with the serum creatinine at 1.0 mg/100 ml.

On January 6, 1971, after steroid preparation with 200 mg of cortisone acetate given intramuscularly before operation (repeated on the day of surgery and the following day), left total hip arthroplasty was performed with insertion of a stainless steel Charnley prosthesis. Sixteen days later the procedure was duplicated on the right hip. Immunosuppression was maintained at preoperative levels of azathioprine (2 mg/kg/day) and prednisone 12.5 mg/day). Recovery was uneventful except for a temporary moderate rise in serum creatinine,

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

which promptly returned to normal levels after four consecutive days of treatment with intravenous injections of methylprednisolone (1 gm/day).

Within three months the patient was walking normally without support. Over the ensuing months he returned to farming, including the lifting of 29.5-kg bales of hay. In addition, he started working 40 hours a week in a factory, so that by September 1971, he was working 90 hours per week regularly. He has continued this workload until the time of this report, 38 months after renal transplantation. The serum creatinine value remains at 1.15 mg/100 ml. The patient takes a maintenance dosage of prednisone—10 and 7.5 mg on alternating days—and a daily dose of 150 mg of azathioprine. His health is excellent except for continuing mild hypertension (160/100 mm Hg).

Comment

This case illustrates full rehabilitation of a patient after treatment for two severely disabling disorders. The avascular necrosis was no doubt secondary to relatively high doses of steroids ingested for several months after a rejection episode. Recently, we have substituted intravenous injection of methylprednisolone for oral doses of steroids in the treatment of rejection, avoiding more than 25 mg of prednisone per day by mouth.[1] This change has resulted in a rather low incidence of avascular necrosis (1.5%—1 of 67) as compared to our previous experience (9%—5 of 53) in patients receiving higher oral doses of prednisone.[2] The magnitude of the operation necessary to correct this condition and the patient's surprising tolerance are indications of the resilience we have noted in the majority of patients whose transplants are successful. This patient's involvement in heavy physical labor likewise attests to the capacity of such patients to lead a normal life.

The most important single factor in rehabilitation, in our opinion, however, is motivation. In our experience the patient who is positively oriented toward specific goals inevitably performs superiorly. It is our impression that one of the prime considerations in acceptance of a patient as a potential transplant recipient should be a strong desire to return to a productive and normal life in his community. The present patient is illustrative of such an outlook.

Cerebral Schistosomiasis

A Report of 10 Cases Caused by Schistosomiasis Japonica

THOMAS A. HAEDICKE, COLONEL, USAR (MC)

THE FIRST RECORDED evidence of central nervous system involvement by Schistosoma japonicum was published in 1906.[7] In that year Tsunoda and Shimamura[7] described a case which was characterized by a right-sided hemiplegia and Jacksonian convulsions. Many ova of Schistosoma japonicum were demonstrated at autopsy in the cortex, choroid plexus, basal ganglia and meninges.

The ova of Schistosoma japonicum always affect the brain, leaving the spinal cord untouched. The ova of Schistosoma haematobium[9] and Schistosoma mansoni,[6] on the other hand, affect primarily the spinal cord and only occasionally the brain.

Gama and De Sa[6] reported the first case of Schistosoma mansoni involving the spinal cord in 1945. Their case showed signs of spinal fluid block and the symptoms were typical of a flaccid paraplegia. Ova of Schistosoma mansoni were found in some pieces of tissue removed from the conus medullaris.

Kane and Most[4] observed 27 cases due to Schistosoma japonicum from October 20, 1944, to May 1, 1946. A clinical diagnosis was made on 22 of these cases. The remaining five were diagnosed from sections of tissue removed from the brain at operation.

Carroll[5] reported five cases in American troops that developed cerebral symptoms within seven months of exposure on the island of Leyte. Practically all of the American troops that developed this infection obtained it either from Leyte or from Mindanao in the Philippines.

Tsunoda and Shimamura[7] feel that the ova arrive by means of arterial embolism. Greenfield and Prichard[8] maintain that the female is lying within one of the cerebral sinuses and deposits her eggs in the smaller venous radicles entering the sinus. There are many other theories as to the route that is taken by the parasites, and they are well summarized by Speigel.[1] The mechanism of spread via the vertebral veins has not been mentioned previously, and it is felt that the involvement of the brain could be explained by ova traveling this route.

Many of the patients diagnosed as having cerebral schistosomiasis recovered without any treatment; Tillman[11] reported several that recovered

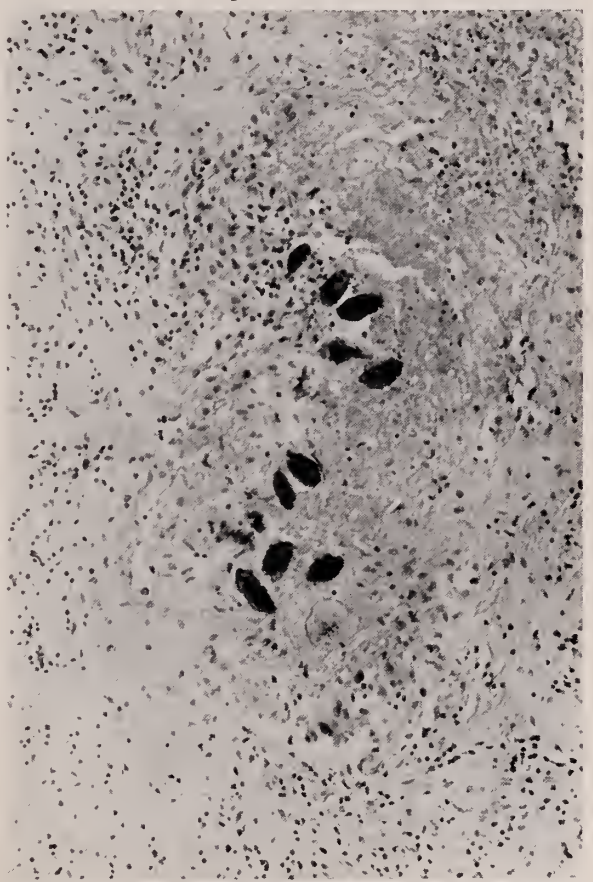

Fig.1—Section of brain showing parasites in cross-section. These measure 30-1000 micra in size, the shortest to the longest diameter. The outer layer is composed of a refractile chitinous layer. The parasites are located in the tubercles of necrotic material.

Dr. Haedicke is a former Chief, Tropical Disease Section, Walter Reed Army Hospital, Army Medical Center, Washington, D.C. Present address: Route 1, Box 16-6, Pike Road, Alabama 36105.

Present Assignment: Medical Director, Medical Services Administration, Alabama Department of Public Health, Montgomery, Alabama.

from confusion, aphasia and hyperreflexia without any treatment.

A few cases were operated on because the diagnosis of cerebral schistosomiasis was not entertained, or because it was felt that a operation would alleviate some of the symptoms. Watson, Murphey and Little[3] reported a case that was operated on after a ventriculogram showed a large expanding lesion in the left parietotemporal region. It was necessary to perform a second craniotomy four months later because the seizures were uncontrolled on large doses of dilantin and phenobarbital.

Faust and Meleny[10] have given us an excellent monograph on schistosomiasis which covers the involvement of the central nervous system. The most important symptoms that these patients have are hemianesthesia, visual field defects, hemiplegia, headaches, paresthesias, unconsciousness and epileptiform seizures. When any of the above symptoms appear and the patient has a history of schistosomiasis, Cutler[2] recommends the institution of early treatment in selected cases, regardless of the fact that ova cannot be demonstrated in stools.

The ten patients in this report developed their infection on the islands of Leyte and Mindanao in the Philippines.

Case 1

A 28-year-old white male was in a combat engineer group engaged primarily in bridge building under fire. In December of 1944, while on Leyte, he spent most of his time working in the water.

Exposure

The men engaged in bridge building had been warned to stay out of water as much as possible because of the possibility of schistosomiasis in that areas.

Early Symptoms

During that time he developed red spots and itching on his forearm. Approximately one week after the skin lesions became evident he had diarrhea for one day consisting of five to six fairly loose stools. In February of 1945 he was sent to the hospital for a 10-day periodic check up. Prior to going he had an elevated white count. Several stool examinations were performed, none of which showed any evidence of schistosomiasis. He was then returned to duty with the recommendation that stools be examined again in one month. One month later enroute to Okinawa he developed severe headaches, nausea, vomiting, anorexia and marked weakness. Gradual improvement was noted following bed rest, but on his arrival at Okinawa in April 1945, he had further frontal headaches and dizziness, which increased in severity.

Localizing Symptom

On 1 May it was found that he could not focus his eyes. He had three episodes of rather severe objective vertigo, each one two minutes in duration, during which his entire body felt as if it were rotating from right to left. The headaches gradually became more violent and he was placed in quarters. During this time he began to vomit and felt as if he would have to vomit each time he changed his position in bed. He did not improve on outpatient treatment and was evacuated to an Army General Hospital in the United States on 11 June 1945.

Physical Findings

Examination at that hospital showed bilateral choked discs, hyperactive reflexes everywhere, complete left homonymous hemianopsia and a left positive Hoffman's sign. A *ventriculogram* showed a shift of the ventricles, including the third ventricle, to the left with deformity of the right lateral ventricle. This deformity suggested a mass pressing upon the ventricles from above and laterally. A small amount of material taken through a needle showed inflammatory tissue containing numerous eosinophils. On 12 July the patient had a left-sided generalized convulsive seizure associated with paresthesia of the left half of the body.

Results of Operation

He was operated on 16 July; a mass 3 cm. in diameter was removed from the right occipital lobe, and he had an unremarkable postoperative course. There were no seizures following the operation. He showed some incoordination and unsteady gait during the first month, but this gait improved and became satisfactory. He had a mild persistent left homonymous hemianopsia and a mild

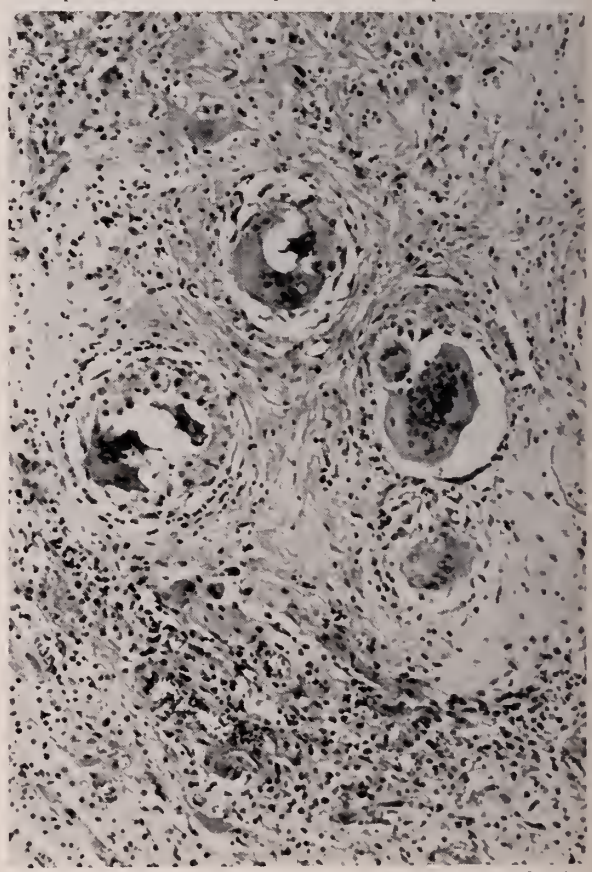

Fig. 2—Section of brain showing parasites engulfed by giant cells within the tubercle.

central type of left facial weakness with some mild weakness of the left fifth and ninth nerves. Electroencephalograms showed only a small-focus low wave arising in the right parieto-occipital region. White blood counts were within normal limits. Eosinophile counts were 5% to 9%. His white count prior to the operation had shown 10% to 12% eosinophils.

Pathology

Microscopic sections revealed no architectural outline. The sections were composed of numerous, small, round cells with colorless cytoplasm; there were also larger cells with abundant pink cytoplasm, suggestive of epithelioid cells. In addition, there were many eosinophils present and a suggestion of epithelial arrangement around some blood vessels. Pathological diagnosis: Inflammation, granulomatous, suggestive of schistosomiasis. (Figures 1 and 2).

This patient was undoubtedly exposed to infection on several occasions since he was a combat engineer. The elevated white count during his first hospitalization indicates that he had schistosomiasis at that time. He was treated with 1.8 grams of tartar emetic following the operation, and a three month follow-up showed great improvement.

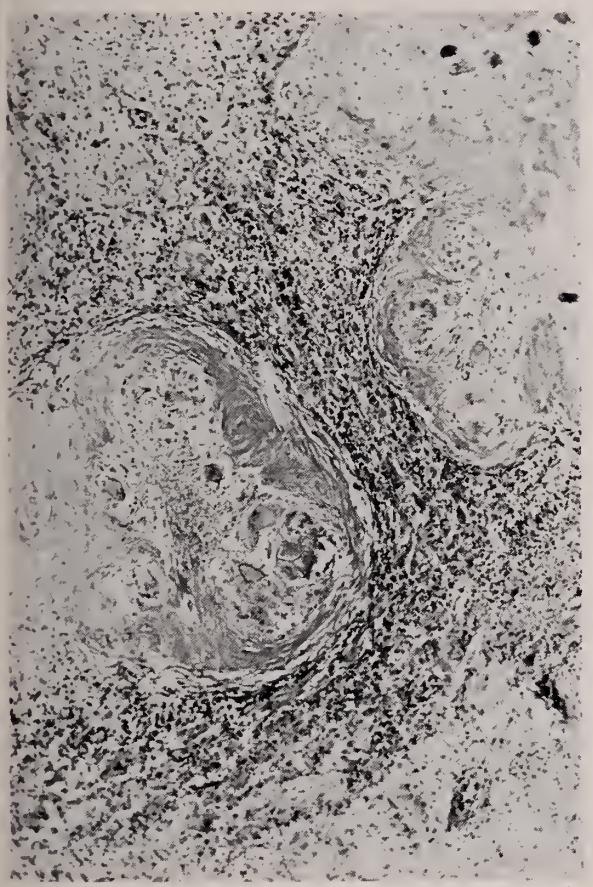

Fig. 3—In this section of brain marked lymphocytic and plasma cell infiltration can be seen ringing the tubercle. In the center of the tubercle can be seen cysts with refractile walls.

Case 2

Exposure

A 29-year-old while male, who was assigned to the Engineers building bridges on the Island of Leyte, was exposed to fresh water containing cercariae of Schistosoma japonicum.

Early Symptoms

At that time there was an onset of severe frontal headaches not related to time of day or activity, and not relieved by aspirin or codeine but by morphine and pantopon. Approximately one month after the headaches had started, they occurred more frequently and persisted throughout most of the day. About two months after their onset the patient began having generalized convulsive seizures. His headaches continued through the six months prior to admission to Walter Reed Army Hospital, and three convulsive seizures occurred during that time. The past history was essentially negative; there was no family history of epilepsy or other mental diseases.

Physical Findings

Physical examination made in September 1945 was essentially negative, except for astereognosis of the left hand. Xrays of the skull, AP and lateral, were negative. *Ventriculography* showed ventricular shift to the left side with failure to fill the right posterior horn.

Results of Operation

In view of the convulsive seizures, the intensity of

Fig. 4—View of same section shown in Figure 3 under high power showing cysts with refractile walls within the area of granulomatous reaction.

pain associated with the headaches, the astereognosis of the left hand, and the ventricular shift to the left side, a right occipitoparietal bone flap was turned down. At this operation, a large nodular racemose type of tumor was found infiltrating the right occipitoparietal area.

Pathology

On gross examination portions of this tumor appear to be calcified. In the granulomatous area, the tubercles are both the hard and soft varieties; in the center of both tubercles, there is a cyst with a refractile wall; there is a marked lymphocytic and plasma cell ring around the tubercle. Pathological diagnosis of Schistosomiasis japonicum was made because of the size and occasional retained original configuration of the ova (Figures 3, 4 and 5).

This second patient became ill four months after his first exposure to water containing cerceriae of Schistosoma japonicum. The convulsive seizures he manifested were more severe than those found in epilepsy. His stools were positive for ova of Schistosoma japonicum following the operation. He was treated with tartar emetic 1.78 grams with complete relief of symptoms after a period of three months.

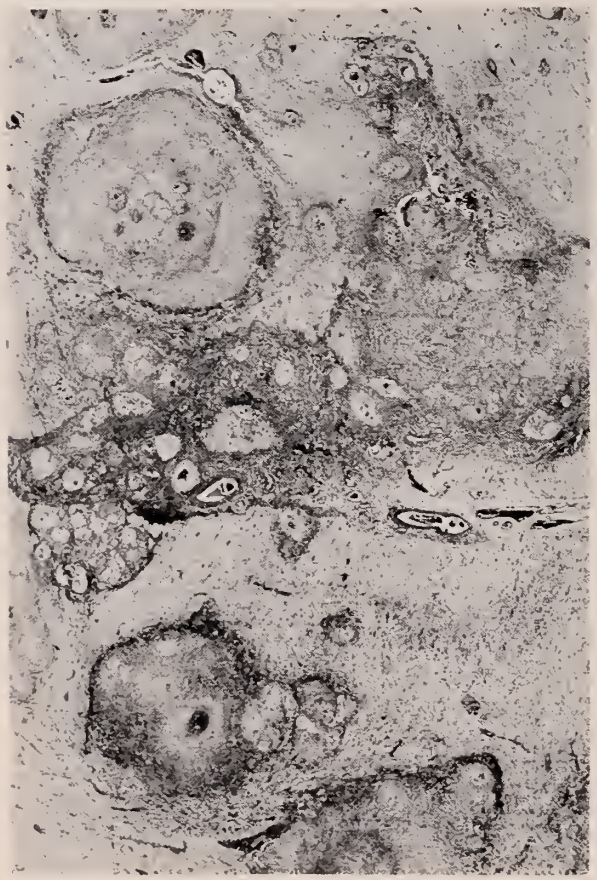

Fig. 5—Brain. Coalescence of tubercles is visible in this section.

Case 3

A 25-year-old white male became ill while on Leyte in October 1944 shortly after he began wading in fresh water streams there.

Early Symptoms

In January 1945 he had a severe nonproductive cough with vomiting and diarrhea. After leaving Leyte he went to Okinawa and felt perfectly well until May 1945 when he had a generalized convulsion. He was subsequently returned to duty. In June 1945 severe frontal headaches began and gradually increased in intensity. They were relieved with aspirin and codeine. In October 1945 the patient had another convulsion and also noted intermittent numbness of the right hand and increasing difficulty in writing. On 4 November 1945 he had a generalized convulsive seizure with trembling and twitching of the right side of the tongue and temperature of 96° to 102°. His speech was slurred and both optic discs were blurred. Laboratory studies revealed a leukocytosis with 11% eosinophilia. He was evacuated back to an Army General Hospital where a spinal fluid examination revealed 75 white cells, 90% polymorphonuclear, and a total protein of 100 mgm. percent.

Results of Operation

A craniotomy was performed on 13 December 1945 with a granulomatous tumor removed from the left

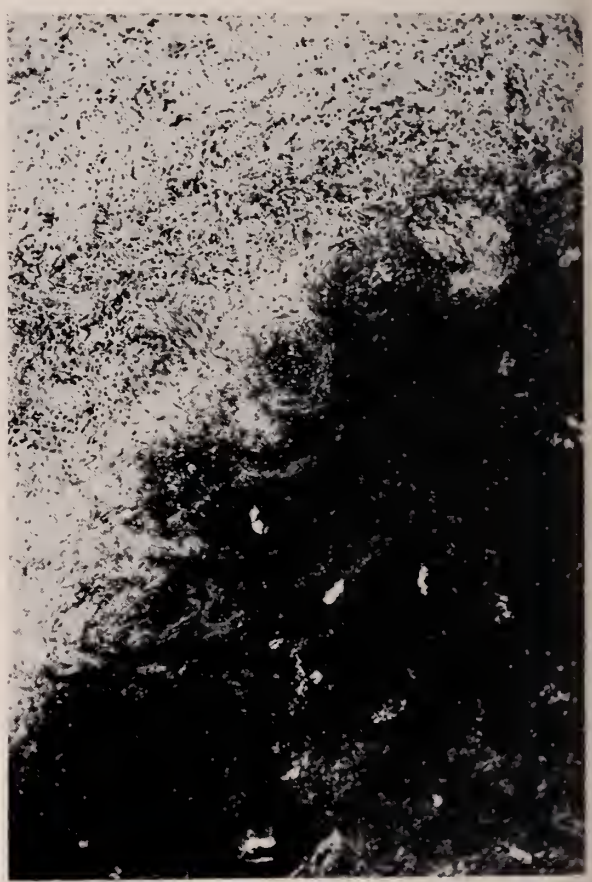

Fig. 6—Section of brain showing dense scar tissue made up of loose recently laid down mucoid collagen containing fibroblasts, plasma cells, numerous lymphocytes, neutrophiles, eosinophiles, and macrophages.

parietal cortex, which was subsequently shown to be due to Schistosoma japonicum with surrounding inflammatory reaction. He was then given a course of 75 cc. of fuadin intramuscularly. His stools were positive for Schistosoma japonicum ova. He was then placed on two dilantin tablets, 1½ grains each daily, following his operation. In March 1946 he was transferred to another Army General Hospital for more specific treatment. There he received a 30-day course of tartar emetic, and then had a follow-up of approximately 30 stools, all of which were negative.

Physical examination on admission to Walter Reed Army Hospital was essentially negative, except for a mild speech defect and weakness in the right hand. The reflexes were equal bilaterally, lungs and heart were normal, and the muscular system was essentially normal.

Laboratory findings in October 1946 revealed: Red blood count, 5,000,000 cells per cubic millimeter; hemoglobin, 98%; white blood count, 7,200 cells per cubic millimeter; neutrophils, 53%; lymphocytes, 43%; eosinophils, 4%. Sedimentation rate, 1. Wintrobe urinalysis, negative. Spinal fluid: Total proteins negative; cells—two lymphocytes. Six stool examinations were negative for Schistosoma japonicum ova.

This third patient continued to have generalized convulsions approximately once each month in spite of dilantin 300 mg. each day. His case is of particular interest because of his continued symptoms following the operation and treatment from fuadin and tartar emetic. He was discharged from the hospital on 600 mg. of dilantin a day. A three-month follow-up has shown that his symptoms are completely controlled.

Case 4

A 22-year-old white male whose present illness dates to 27 March 1945, while on Luzon, developed a generalized convulsive seizure followed by a violent headache of fifteen minutes' duration. The history disclosed prolonged difficulty with a left infraorbital abscess in 1926, at the age of four, which followed the removal of several teeth and was complicated by cellulitis, abscess, and osteomyelitis of the left side of the face. The patient had spent three years prior to this present illness in the Southwest Pacific, in Hawaii and the Philippine Islands. He bathed in the fresh water streams on Leyte, but he had no illness or any occasion to report to sick call during the entire three years in the Southwest Pacific. The day after his grand-mal seizure, he had an aura of bad taste, nystagmus with a rapid component to the left, and dilated pupils, a twisting of his head to the left, severe opisthotonos, severe cyanosis, and a major clonic seizure. Immediately after the seizure an examination revealed a positive Babinski on the right. An hour later, he again became unconscious for fifteen minutes, with a constant jerking of the right arm and leg. After that he had diplopia and constant severe headaches accentuated by turning, flexing and jarring the head. He walked with an unsteady gait, with a tendency to fall to the right, and his speech became slurred.

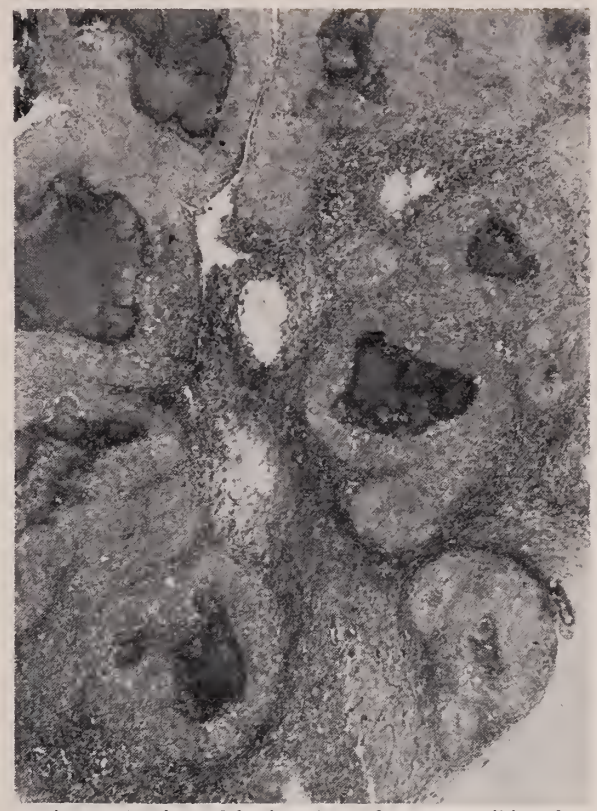

Fig. 7—Section of brain where the most striking feature in the mass of scar tissue was the broad geographic area of necrosis that resembled caseation necrosis.

Fig. 8—Brain. Many round cells present with colorless cytoplasm. An epithelial arrangement around some blood vessels is noted.

Physical Findings

Physical examination at this time showed bilateral, diminished corneal reflexes; bilateral sixth nerve palsy; papilledema of both retinae, more marked on the right; dysmetria, worse on the left; stiff neck; erratic response to pinprick, worse on the left; pupil dilated on the left; bilateral impaired hearing for high tone; and fanning of the toes bilaterally on plantar stimulation. An electroencephalogram revealed an irregular focus in the right anterior temporal region; a ventriculogram showed the lateral and third ventricles shifted to the left. In view of these findings and history, it was felt that the ventriculogram was positive evidence of a mass in the right frontotemporal area.

Results of Operation

An operation performed on 23 May 1945 revealed a hard, firm, dense mass in the right frontotemporal area, about the region of the Sylvian fissure. "The specimen consisted of a mass of firm, white tissue, measuring two cm. in diameter, and multiple additional fragments of firm, white tissue totaling 3 x 1 cm."

Pathology

Sections show that most of the tissue is composed of a dense scar made up of loose, recently laid down mucoid collagen containing many young fibroblasts, large masses of plasma cells, numerous lymphocytes, polys, eosinophils, and macrophages. In the necrotic areas, and especially in the macrophagic borders, there are found numerous parasitic forms. About three hundred of these were studied in numerous sections. The parasitic forms all have an irregular, thin, elastic-like, dense outer shell. Within the shell is a mass of pale protoplasm containing small, round, blue particles resembling lymphocytic nuclei. These parasites are typical of Schistosoma japonicum (Figures 6 and 7).

This fourth patient's illness was typical of the type manifested by many cases of cerebral schistosomiasis. The onset of a convulsive seizure was often sudden and without warning. His seizures were relieved by the operation, but there is no extensive follow-up on his ultimate course.

Case 5

A 27-year-old white male began to have left frontal headaches, blurring of vision and dizziness on 15 November 1945 while on the island of Leyte. On 20 November 1945 after a series of epileptic convulsions he was admitted to an Army Hospital in Okinawa, where neurological examination revealed choking of the left optic disc, dilated and fixed pupils, and conjugate deviation of the eyes to the left and upward. There was spastic weakness of the right upper extremity, and hyperactive deep tendon reflexes on the right, with absent superficial reflexes on that side. Stools were negative for ova of Schistosoma japonicum. A spinal fluid examination showed 44 lymphocytes. The patient was transferred to the United States, arriving at an Army hospital on 2 January 1946.

Results of Operation

On 17 January 1946 a craniotomy was performed, and a tumor mass removed from deep within the central region of the left parietal lobe of the brain. Histologic examination of the brain revealed findings compatible with Schistosoma japonicum infestation. Shortly afterward his stools were found positive for ova of Schistosoma japonicum, and it was therefore felt that the granulomatous lesion in the brain was due to schistosomiasis.

Medical Therapy

He was given 63 cc. of fuadin intramuscularly in February and March of 1946. On 7 March 1946 his stools were again positive for Schistosoma japonicum, and he was transferred to another Army hospital for more adequate treatment. On 3 April 1946 ova of Schistosoma japonicum were again found in his stools, and he was given a 30-day course of 2.25 grams of intravenous tartar emetic. Subsequently he had 28 stools specifically examined for ova of Schistosoma japonicum, and they were all negative. As he continued to have convulsions dilantin therapy consisting of 100 mg. each day was instituted.

Progress

Physical examination on admission to Walter Reed Army Hospital was negative, except for tingling, numbness and clumsiness in his right hand, and weak and dizzy spells part of the time. Muscular weakness of his right wrist and hand was noted. He also had blurring of the disc margins bilaterally, and a moderate speech defect. There was minute depression in the left frontoparietal region as evidence of his previous surgery at an Army hospital. Deep reflexes were hyperactive bilaterally. No muscular or sensory changes were noted in the lower extremities.

Laboratory findings: Blood count: Red blood cells, 5,000,000 per cubic millimeter; hemoglobin, 15 grams (Turner's method); white blood count, 6,350 per cubic millimeter; neutrophils, 53% lymphocytes, 32%; eosinophils, 13%; basophils, 2%. Urinalysis, negative. Spinal fluid showed normal pressure and normal chemistry. Six stools were negative for ova of Schistosoma japonicum. Hookworm ova were found in the stools. Xray of the chest was negative. An electrocardiogram showed regular sinus rhythm, and elevated RT segments, leads II and III.

During the month that we observed the patient he had one generalized convulsive seizure. He continued taking dilantin each day and was discharged from the hospital with essentially the same neurological findings as he had on admission.

This fifth patient had a very optimistic outlook on life in spite of his many convulsive seizures before and after his operation. Dilantin was very effective in preventing seizures. The residuals of weakness and speech defect were probably not permanent since only 13 months elapsed from the beginning of his present illness to the time of discharge. The high eosinophile count that persisted for a whole year is of considerable interest.

Case 6

Early Symptoms

A 27-year-old patient who arrived on Leyte in November 1944 and on many occasions bathed in fresh water there was hospitalized on 30 January, 1945, because of weakness and insomnia. At that time he was

very uncooperative, poorly oriented, and had urinary incontinence. During the first week of hospitalization he became comatose with signs of multiple nervous system involvement, along with marked spasticity and rigidity of all of his extremities. A diagnosis of schistosomiasis with cerebral involvement was made after several stool examinations revealed the presence of ova of Schistosoma japonicum. He was treated with 45 cc. of fuadin from 2 February to 22 February, with definite improvement. From 26 February to 16 March he received 45 cc. of fuadin, making a total of 90 cc. After this treatment he was evacuated to the Zone of the Interior and arrived at an Army hospital on 26 June 1945.

Physical examination there revealed an enlargement of the liver three cm below the right costal margin, and bilateral positive ankle clonus with coarse hand tremor. He also exhibited memory difficulties and motor aphasia. He was given two courses of treatment for Schistosoma japonicum infestation: the first consisting of 1.8 grams of tartar emetic from 30 June to 30 July 1945, the second of 100 cc. of fuadin from 16 September to 18 September. In April 1946 he received 2.22 grams of tartar emetic given intravenously. On admission to Walter Reed Army Hospital there was nervousness, tremors, poor memory, and difficulty in walking and in using the right word.

Physical examination revealed tenderness in the right upper quadrant, and the liver was one cm below the right costal margin. Neurological examination showed marked weakness in the left upper and lower extremities. Reflexes were hyperactive bilaterally; ankle clonus was present on the left; there was a small area of anesthesia on the dorsum of the left foot and on the left hand, and there was slight blurring of the margin of the optic discs bilaterally. He had a very poor memory and a little speech defect.

Laboratory work: Red blood cells, 5,000,000 cells per cubic millimeter; hemoglobin, 14.3 grams (Turner's method); white blood cells, 10,000 per cubic millimeter; neutrophils, 74%; lymphocytes, 23%; eosinophils, 2%; basophils, 1%; icteric index, 4% cephalin flocculation, negative; corrected sedimentation rate, 2; 20 stool examinations, negative for ova of Schistosoma japonicum.

End Result

The patient complained continuously of muscle weakness, muscle cramps and headaches. His condition improved only slightly on a regimen of active and passive physical therapy. The neuropsychiatrist disclosed a psychotic reaction in which auditory hallucinations, paranoid trends and memory impairment were the most significant features.

This sixth patient was of considerable interest from many standpoints. He was comatose on one occasion but never had any generalized convulsive seizures. His stools were positive for ova of Schistosoma japonicum during his first admission to the hospital. He was diagnosed and treated soon after the onset of his initial symptoms, but he never completely recovered. The psychotic reaction that he manifested was not found in any of the other nine patients and is unusual as far as the cases recorded in the literature are concerned. It is felt that he will not improve any further since it was approximately two years from the onset of his present illness until his discharge. The cells damaged in the brain will probably never recover.

Case 7

Early History and Symptoms

A 25-year-old white male, captured by Japanese at Bataan in April 1942, was on the Death March for 12 days with almost no food while marching 100 miles. He was a prisoner for 3½ years at Mindanao. During that time he had approximately 70 attacks of dysentery, with blood and mucus, nausea, vomiting and tenesmus. He received sulfonamide therapy for his diarrhea. Since his liberation and for the past year and a half, he has had diarrhea, alternating with periods of constipation. As a prisoner of war he developed a tingling and severe burning of the plantar surfaces of both feet, followed by swelling of the ankles, feet, legs, hands and face. This was interpreted as the wet and dry stages of beriberi. The tingling persisted for almost a year and, for a period of time, was accompanied by paralysis bilaterally from the hips down. The burning decreased following vitamin B_1 injections, and the paralysis subsided; however, the numbness and tingling continued in his toes and fingers.

Cerebral Symptoms

In 1943, approximately one year after the patient was captured, he began to have sudden generalized convulsive seizures, not particularly related to any activity, time of day or emotional strain. After regaining conscious he would remain weak for several hours. These attacks occurred two to three times a week for the first six months, and then once every two months. Preceding these attacks he experienced sensations of being off balance, particularly when arising from a sitting or lying position. The room appeared tilted for just a few minutes, and then his vision spontaneously corrected itself. As a prisoner of war he had also experienced bleeding gums, areas of anesthesia of the palate, and cheilosis, all of which have since subsided, except for bleeding of his gums while brushing his teeth. He has persistent fatigue and, from time to time, nausea and vomiting, both of which were quite severe while he was a prisoner of war. His symptoms cleared up for several months immediately after his release, but it then recurred, and is still present, especially after breakfast. When he was captured, he weighed 145 pounds. He weighed 111 pounds on release. His lowest weight was 84 pounds; he now weighs 145 pounds.

Physical examination on admission to Walter Reed Army Hospital was essentially negative, except for tenderness over the abdomen, neuritic pains in both legs, flabby musculature, decreased sensation to pain and light touch at the ends of fingers and toes, and blood pressure of 120/90.

Laboratory findings: Parasites and ova: Trichuris trichiura and *Schistosoma japonicum ova*. Blood count: red blood cells, 5,650,000 per cubic millimeter; hemoglobin, 15.5 grams (Turner's method); white blood cells, 12,000 per cubic millimeter; neutrophils, 54; lymphocytes.

45; eosinophils, 1. Sedimentation rate, 2. Total proteins, 8.9 grams percent; albumin, 6.25 grams percent; globulin, 2.65 grams percent; albumin-globulin ratio, 2.36. Xray of the chest, negative. Barium enema, negative. Proctoscopic examination, negative.

Provocative Treatment

This patient was immediately started on multivitamin therapy, supplemented by vitamin B_1 injections in view of the residuals of beriberi that were evident. Approximately 20 stool examinations were negative for Schistosoma japonicum ova; however Trichocephalus trichiura ova were found on several examinations. Since this patient had a history suggestive of exposure to schistosomiasis and intermittent diffuse abdominal tenderness with cerebral symptoms similar to those experienced by other patients having cerebral schistosomiasis, it was decided that he should receive a course of tartar emetic therapy. This was started on 9 June 1947, up to a total of 2.22 grams. After the fifth injection his stools became positive for ova of Schistosoma japonicum. He experienced little toxicity to the tartar emetic until after 15 days of therapy consisting of 0.9 grams. The toxic symptoms, which consisted of generalized aching and nausea, continued until the completion of therapy. A generalized convulsive seizure occurred 15 days after the onset of this therapy. There was marked improvement following the tartar emetic therapy, and during the subsequent four months there were no convulsive seizures.

This seventh patient was one of the prisoners of war who had constant exposure to the cerceriae of Schistosoma japonicum for approximately three years. He is one of the few who developed cerebral manifestations and also one of the few that showed ova in their stools after the beginning of antimony therapy. It is felt that his prognosis is excellent and that he may have a complete cure.

Case 8

Exposure and Early Symptoms

A 26-year-old white male was exposed to schistosomiasis while bathing in a stream in Leyte in December 1944. He continued in his usual state of good health until the last week of January 1945, at which time he developed diarrhea, blurring of vision, weakness, manual stiffness and clumsiness, but no significant rash or urticaria at that time. There was no abdominal or muscular pain, but occasional nausea and vomiting. He was hospitalized at a general hospital overseas on 1 February 1945 with headache, fever and mental confusion. The medical officers thought that he had a psychosis of a catatonic type. His history stated that during the first two weeks of hospitalization he was irrational. His white count showed a moderate leukocytosis with a marked eosinophilia. His low-grade fever suddenly rose to 107 degrees after the first week. Repeated spinal fluid examinations were not remarkable. One stool examination was performed and was negative for schistosomiasis; however, since schistosomiasis was very prevalent in that area, he was given a course of fuadin consisting of 40 cc. with little improvement.

Cerebral Symptoms

During the latter part of February 1945 he developed signs of a spastic quadriplegia with a positive Babinski on both sides. His eosinophilia persisted and his sedimentation rate became elevated. During early March 1945 he received a second course of fuadin with marked improvement in strength. He was evacuated to another general hospital in May 1945 where it was revealed that he had a spasticity of the legs with atrophy and hyperreflexia and a negative Babinski bilaterally. Marked weakness in the hands and eosinophilia were also noted. Spinal fluid examination remained negative. On 15 June 1945 Schistosoma japonicum ova were found in his stools, and he was then given a 30-day course of tartar emetic intravenously, up to a total of 1.8 grams. Following this course of therapy there was some improvement in his strength; but during the following six months the patient noted little subjective improvement. His appetite was good, but he was still 10 pounds underweight. He noted some right upper quadrant pain during November 1945, and was started on another course of tartar emetic; but as it produced a dermatitis, it was discontinued. He was started on fuadin in March 1946, but this was also discontinued because a dermatitis appeared on the fourth injection.

Disabling End Result

He was transferred to an Army hospital on 9 April 1946. He was somewhat improved, but showed generalized hyperreflexia with absence of the superficial reflexes. There was a flaking of the skin over the entire body with a mild redness. Motor power was good in the upper extremities, but was definitely impaired in the trunk and legs. There was diffuse atrophy. A positive Babinski and Hoffmann were present bilaterally, also ankle and patellar clonus bilaterally of the sustained type. There was a 4% eosinophil count and a sedimentation rate of 4 mm. The electroencephalogram was essentially negative. The patient was fitted with a drop foot brace with ankle straps. A regimen of prostigmine and extensive physiotherapy was instituted, but no great change was noted in the spasticity during and after treatment.

The patient was transferred to Walter Reed Army Hospital on 9 November 1946. During his 10-month stay there he was given extensive physiotherapy treatment. Walking became satisfactory with the aid of canes. His mental attitude improved remarkably, and he was able to pass his examination for a driver's license, using a hand-controlled car. However, the generalized spasticity and weakness in all muscles persisted.

This eighth patient demonstrated the most severe residuals we have seen. He was followed for more than two years, and it is felt that the generalized spasticity and weakness in all muscles are permanent. He represents one of the few cases with bilateral and diffuse involvement; the symptoms and signs were usually localized to the right or left side. He was given two courses of fuadin therapy before ova of Schistosoma japonicum were found in his stools.

Case 9

A 27-year-old patient, a prisoner of the Japanese on Mindanao from 1942 until February 1945, suffered dur-

ng that time from malnutrition, avitaminosis, malaria, hookworm infestation and various undiagnosed types of dysentery. He was liberated in February 1945 and was immediately evacuated to the United States.

Cerebral Symptoms

Because of neurological symptoms suggestive of brain tumor he was transferred to an Army hospital, where he was found to have intestinal schistosomiasis with cerebral manifestations and where he was treated with two courses of fuadin consisting of 45 cc. each. In January 1946 he was transferred to another Army hospital and was in fairly good health except for fatigability, photophobia, a tendency to become mentally fatigued, and loss of strength in the left arm and leg. He also had mild tinnitus with occasional sporadic attacks of diarrhea.

Physical examination was essentially negative except for muscular weakness of the left arm and leg.

Laboratory data revealed red blood cells of 5,270,000 per cubic millimeter; hemoglobin of 15.5 grams (Turner's method); white blood cells of 10,400 per cubic millimeter; neutrophils, 54%; lymphocytes, 37%; monocytes, 4%, and eosinophils, 5%. Stool examination was positive for Schistosoma japonicum ova on 21 January 1946. Bromsulfalein test showed 10% retention in 45 minutes. Icteric index was 4. Schistosomiasis skin test was positive. Eosinophile count varied from 10% to 14%. Blood urea nitrogen was 14 milligrams percent. Bromsulfalein test revealed 25% retention in 45 minutes on one occasion and 6% retention in 45 minutes after 15 days. Following the initial finding of Schistosoma japonicum ova approximately 30 stools were negative for pathogenic parasites and ova. Repeated blood counts showed diminution of the eosinophils to 3%. Thymol turbidity was 5.7 units. A spinal tap was done and showed no white or red blood cells, but did reveal a positive globulin and a spinal fluid protein of 48 milligrams percent. The spinal fluid smear was negative for ova of Schistosoma japonicum. The patient was seen by a psychiatric consultant who felt that he had organic brain disturbance and that his intelligence quotient was very high. The patient was also seen by the tropical disease consultant, who confirmed the diagnosis of chronic schistosomiasis, intestinal and cerebral, and who felt that further therapy for infection with Schistosoma japonicum should be instituted. The patient continued to show marked improvement.

Deterioration

It was believed that the central nervous system defects were demonstrable only on special psychological testing and that repeated bromsulfalein tests should be done and stool examinations evaluated further. Following a course of 100 cc. of fuadin therapy the patient developed a hepatitis with abnormal bromsulfalein retention and a moderately increased icteric index. On a high carbohydrate, high protein, low fat diet with vitamin supplements the nausea and anorexia subsided. In June 1946 he felt that he was declining, having increased fatigability, return of tinnitus, a mild feeling of confusion, particularly when tired, and considerable memory loss. Because of this symptomatology he was given a 30-day course of 2.22 grams of tartar emetic. The tartar emetic was well tolerated, and resulted in considerable subjective improvement, which continued during the following month. Still present, however, were clumsiness of the left hand and a very slight tendency to sway backward upon shutting his eyes.

Physical examination on admission to Walter Reed Army Hospital was essentially negative except for muscle weakness of the left arm and leg; it was also noted that he talked very slowly and was very self-conscious. He was placed on physiotherapy and symptomatic care, but he improved very little during six months of observation.

This ninth patient was a major in the infantry: the only officer I know who developed cerebral manifestations from his schistosomiasis. He was more concerned about his future than the enlisted men since he had a "superior type of mind" prior to his infection. I think that the remaining problem in this patient was continuous psychotherapy. He will probably return to near normal only after years of psychiatric help.

Case 10

Exposure and Symptoms

A 25-year-old black male was stationed at New Guinea from December 1943 to November 1944, and on Leyte from November 1944 to May 1945. His present illness began on 18 January 1945 while he was on Leyte. He had bathed and washed clothes in the local rivers until December 1944; and he was continuously in swampy water and rice paddies while on an engineering construction project. During this time there was no record suggestive of a cercarial rash. The present illness began with rapid swelling about the face, trunk, and upper extremities, with associated mild upper abdominal pain not localized to either the right or the left side. The patient turned in on sick call on 24 January 1945 at an Army hospital. During the subsequent month, he could not recall what had transpired.

Cerebral Symptoms

A perusal of the incomplete records revealed that the patient was semicomatose, running an intermittent pyrexia up to 102.6°, and was incontinent of urine and feces. He was in a deep lethargy and when aroused would complain of upper abdominal and chest pain. During this period neurological examination revealed marked weakness in the left arm and leg, with ankle clonus and hyperactive deep reflexes on the left side. The white blood count did not exceed 8,600, and the highest eosinophilic count was 60%. On 5 March an Xray of the chest disclosed a hazy mottling over the lower half of each thorax. The stools were repeatedly negative for ova of Schistosoma japonicum, but it was decided to treat him for schistosomiasis because of the history and clinical picture.

He was given 1.42 grams of tartar emetic intravenously from 10 February 1945 to 4 March 1945 with gradual improvement in his general condition. Because of depression of the T waves in all leads in the electrocardiogram, it was decided to discontinue the above medication, and fuadin was begun intramuscularly, 25 cc. being given between 6 March 1945 and 12 March 1945. After this therapy he was greatly improved and was returned to the United States on 11 May 1945 with mild residual weakness of the left arm and leg.

On admission to an Army hospital on 8 June 1945, the patient's only complaints were fatigability and the fact that he was 20 pounds under his normal weight. There was an eosinophilic count of 14%. Repeated stools were negative for ova of Schistosoma japonicum, but one examination showed a few Anyclostoma duodenale and Trichocephalus trichuria ova. He was transferred to Walter Reed Army Hospital on 7 October 1945 for further therapy.

Physical examination on admission was essentially negative except for weakness of the left arm and leg. Deep reflexes were hyperactive on the left side, but no ankle clonus was elicited. He was 10 pounds underweight.

Laboratory findings were as follows: Red blood count, 4,600,000 per cubic millimeter; hemoglobin, 14 grams (Turner's method); white blood count, 7,800 cells per cubic millimeter; neutrophils, 57%, lymphocytes, 39%, eosinophils, 4%. Stools to the laboratory for ova of Schistosoma japonicum, 36 megative. Proctoscopic examination revealed a few submucosal hemorrhages in July 1945 and was negative in November 1945.

He was placed on extensive physiotherapy treatments and his left arm and leg both became somewhat stronger. During the subsequent six months, however, there was no further improvement.

This tenth patient was exposed to the cerceriae of Schistosoma japonicum on several occasions. His fever during the acute onset of his disease was probably the highest recorded in the patients with cerebral schistosomiasis. His electrocardiogram showed depression of the T waves, but treatment was continued until the course was finished. He had very few residuals when discharged from the hospital.

Summary

1. A summary of the literature on cerebral schistosomiasis is presented.
2. Ten case histories are given with an average follow-up of 18 months.
3. A discussion of the 10 cases is presented with a view to bringing out some of the important points in diagnosis and treatment of cerebral schistosomiasis.
4. Cerebral schistosomiasis should be considered in the differential diagnosis of patients who have symptoms and signs suggestive of a brain tumor and who have been in an endemic area.
5. Combined medical and surgical treatment is necessary in some patients.
6. Ova of Schistosoma japonicum may not be found in the stools of patients having symptoms and signs of cerebral schistosomiasis.
7. Extensive treatment consisting of several courses of tartar emetic should be given every patient diagnosed as having cerebral schistosomiasis.
8. Cerebral schistosomiasis patients should be followed for a minimum of two years.
9. One can expect no further improvement in the residual manifestations of cerebral schistosomiasis after two years.

Spinal Cord Injury

Some Psychological Considerations

ALAN H. ROBERTS, PH.D.

It is paradoxical that, while the bulk of the literature published on spinal cord injury emphasizes the medical issues, some of the major problems are psychological and social. The psychological aspects of the spinal cord injured patient have not been adequately studied or evaluated.

When an individual sustains a spinal cord injury, the first concerns of both the physician and the patient are obviously medical. The patient's acute injury is treated to insure his survival and to minimize the extent of injury. Laminectomy may be performed and there is a period of immobilization for fusion of vertebrae or stabilization of fractures at the site of injury. Once these problems have been treated, long range medical care becomes supportive and inextricably intermixed with psychological and social adjustment. Examples of problems of medical care with these implications include skin hygiene to prevent ischemic ulcers, prevention of urinary tract infection, dietary supplementation, control of spasticity, control of excretory functions and sexual malfunction. The social and psychological components of all of these problems must be taken into consideration if the patient is to make an optimal adjustment.

Motivational, emotional, interpersonal, and vocational problems inevitably originate following the onset of paraplegia. The psycho-social problems require as much emphasis as the purely medical problems in the total ongoing rehabilitation of the patient. Indeed, as Braceland[1] has pointed out: "Medicine is finding that to fulfill its obligations in a changing epidemiology and a changing culture, it is not enough to apply the insights and techniques of pure science. It is equally important to treat the patient against the background of his environment and in light of the personal, interpersonal, and social meaning of the illness."

The long range adjustment of the patient who sustains a spinal cord injury is determined by two primary factors: (1) the premorbid adjustment of the patient and (2) how the patient works through and accepts his disability.

The best predictor of future behavior is past behavior. The greater the degree of "ego strength" possessed by the patient, the better the adjustment to his disability is likely to be. "Ego strength" is determined by the patient's possession of most or all of the following characteristics:[2] good physical functioning, spontaneity, the ability to share emotional experiences, conventional but not fundamental or dogmatic religious beliefs, permissive morality, good contact with reality, feelings of personal adequacy and vitality, physical courage, and lack of fear. Individuals with high ego strength are generally much better able to cope with severe stress than individuals who lack these characteristics. In spite of isolated examples of individuals who became "better people" from a social standpoint after injury than before, generally, severe stress is more likely to disrupt a personality than to improve it. The less well adjusted a person is prior to injury, the more likely he is to have difficulties following the stress.

The person with greater intellectual ability has more opportunities to engage in a variety of activities following his disability than the person with less intellectual ability. However, it is not simply the degree of intelligence but the kind of intelligence, the intellectual orientation of the patient, that affects his future adjustment. The intelligence of some people tends to be channeled into verbal thinking, others tend to have a bodily orientation and they are more concerned with physical interests.

The person whose bodily functioning is severely disrupted by a spinal cord injury will have a better chance of realigning his life if his interests center

Dr. Roberts is in the Department of Physical Medicine and Rehabilitation, University of Minnesota, Minneapolis.

This work was supported in part by Social and Rehabilitation Services Grant RT-2.

on verbal-intellectual pursuits rather than on physical. Unfortunately physically oriented individuals are the ones who engage in the type of activities that increase the probability of accidents.

Impulsivity vs. the ability to delay gratification, other facets of premorbid personality, also have an important bearing on post-traumatic adjustmen.[3,4] A reasonable adjustment to a spinal cord injury would logically require that the patient be able to sustain effort, plan ahead, and delay immediate gratification in favor of more important long-range goals. Again, individuals most likely to sustain traumatic injuries to their spinal cords are those who show more than average impulsivity.

The single most important contribution that the physician can make to the future adjustment of the patient is to inform him as early as possible, and as clearly as possible, about the nature of his injury and his prognosis. Most patients in early stages are not clearly informed of the fact that they have an exceedingly low probability of ever walking.

Two rationalizations are usually given by physicians for delay in informing the patient. First, the physician feels that if he exaggerates the extent of the future disability and is wrong (i.e., if the patient happens to be one of the few who recover function), the patient's faith in physicians will be disturbed. Actually, in the two or three instances that we have observed of a patient recovering more function than he was told he would have, the patient has been both grateful and pleased and credited the doctor and the treatment for his improvement. A second reason often given for withholding accurate, but unpleasant, prognostic information is that if the patient is told he will be unable to walk again, "it will destroy his hope" and he will then have no motivation to become rehabilitated. Our own experience is contrary to this. Loss of motivation over a period of time is more often the result of failure by the patient to achieve unrealistic gains which he has been hoping for, usually on the basis of unclear information or information offered *after his unrealistic expectations have been fixed.*

However, withholding accurate and detailed prognostic information deprives the patient of the chance to grieve over his loss and to appropriately work through his feelings about this loss. There is growing recognition[5] that grief is a complex, but stereotyped, response pattern that includes both psychological and physiological symptoms such as withdrawal, fatigue, sleep disturbance, and loss of appetite. Averill[5] believes that grief is fundamentally a biological phenomenon whose function is related to the maintenance of long-term social bonds. The usual occasion for grief is the loss of a significant object: another person such as a close relative; material things such as wealth; or even a symbolic object such as one's reputation. However, grief may stem not only from the loss of an object, but also from a change in social relationships or in social roles.[6,7] If a change in social role is viewed as an important factor in grief reactions, then grief as a response to a loss of body function is readily explained. Bibring[8] and Becker[9] suggest that grief reactions occur primarily when the change in role leads to loss of self-esteem or otherwise causes the person to feel that his behavior lacks meaning or rationale.

The patient who builds up his defenses against an awareness of loss before he is directly told about that loss, is most likely to continue searching unrealistically for the return of bodily function. When, over a period of months or years, his hopes are unfulfilled, he is likely to suffer a chronic form of depression, a reduction in self-care, and general psychological and physiological deterioration.

The physician can aid the patient in adjusting to his loss by not presenting him with "double messages" concerning his future and prognosis. The practice of standing the paraplegic patient in long-leg braces and offering him a trial of walking during the first weeks or months after the trauma is a common form of double message to the patient. On the one hand, he is told that he is unlikely ever to be able to walk functionally and usefully again; at the same time, a great deal of time and effort by a skilled staff are devoted to teaching him to perform a function that he has previously been told he cannot accomplish.

Some patients demand a trial of walking and this opportunity probably should be given to them. However, the patient should be asked to wait an appropriate period of time before this trial is actually attempted. Since the period of mourning in our society traditionally ranges from three to twelve months the patient should be asked to wait a year and then return for his trial. At that time, when he tries and fails (if indeed he still wishes to try), the effects of the disappointment are likely to be minimized, and his defenses will permit him to respond more appropriately to that

disappointment.

Even the patient with a high degree of "ego strength" will show some degree of "ego decompensation" as the result of the sudden dramatic onset of his injury and loss of function.[10] In addition to the normal brief reaction previously described, typical ego defenses are brought into play and exaggerated. The patient may display symptoms based upon withdrawal, denial, or depression.[11] It must then be determined whether the patient's symptoms constitute a relatively "normal" working through of his reactions to the sudden and serious loss or whether his responses are exaggerated and maladaptive. The most evident characteristic of an abnormal reaction is its excessive nature and its protracted course. When an abnormal reaction is suspected, psychiatric and psychological consultation should be obtained for the purpose of intervening. However, barring a disproportionate reaction, the patient should generally be allowed to work through his feelings concerning his disability at his own pace.

A rehabilitation program that emphasizes activity, motivation, and readjustment may push the patient toward reconstituting experiences before he is ready. The individual is then unable to develop appropriate defenses and new methods of coping with his new situation and new role at his own pace. Perception of this requires great sensitivity on the part of the physician and treatment staff.

Cover Photograph

"Crystal Wonderland"

The cover photograph was taken by Dr. Vernon Lindberg in 1967 during a heavy sleet storm which hit the Twin Cities. He tells the editors that he went out to Cedar Lake to take the photograph, and being improperly dressed for the cold weather, had difficulty in manipulating the lens and making the proper adjustments to the camera.

Photography is a new hobby with Dr. Lindberg and one which he thoroughly enjoys. He is a member of the Minneapolis Color Photo Club which is the oldest color transparency club in the country, having been in existence for 32 years, and, the first camera club in the country devoted exclusively to color photography.

Dr. Lindberg is a clinical Associate Professor in Ophthalmology at the University of Minnesota Medical School and has offices in the Southdale Medical Building in Minneapolis.

Obstruction of the Common Bile Duct

Duodenal Diverticula

HARRY B. NEEL, M.D.

DUODENAL DIVERTICULA are present in from one to six percent of individuals who have x-ray examinations of the upper gastrointestinal tract.[1] Sixty-two to 83% of the diverticula occur in the second portion of the duodenum and nearly all of them are along the concave side, within 2.5 centimeters of the ampulla of Vater.[2]

Although duodenal diverticulum was first described in 1710,[3] the diagnosis was first made in a living individual in 1913 by Case.[4] Farsell and Key[5] performed the first operation for removal of a diverticulum which had been previously diagnosed. Because indications for removal of duodenal diverticula are not common, the number of reported operations is small. Waugh and Johnston[6] reported that of the 30 patients who had operations for duodenal diverticula at the Mayo Clinic prior to 1955, in only eight was the diverticulum the basic reason for operation. Cattell and Mudge[7] stated that only 25 cases of duodenal diverticula were operated on at the Lahey Clinic in a ten year period.

Although the majority of duodenal diverticula are asymptomatic, the complications which occur in about ten percent of patients with diverticula include ulceration, acute inflammation, perforation, hemorrhage, formation of enteroliths and compression of the common bile duct. An unusual complication is biliary and pancreatic duct obstruction accompanied by pain, cholangitis, jaundice, and fever.

The recurrence or persistence of symptoms after cholecystectomy, referred to by some clinicians as the "post-cholecystectomy syndrome," causes the surgeon to consider the possibility of overlooked stones in the common duct, stricture of the duct, or pancreatitis. Another possibility that should be considered is compression of the common duct by a duodenal diverticulum.

The author has cared for two patients, each of whom had had cholecystectomy, who continued to have attacks of severe pain in the upper abdomen. In one patient jaundice had complicated two of the episodes. In each case a duodenal diverticulum was detected on radiographic examination of the upper gastrointestinal tract. Removal of the diverticulum relieved the symptoms and the patients have remained well.

Case 1

A white woman, age 67 years, without a history of previous gallbladder disease, developed acute cholecystitis in June, 1964. As an emergency procedure, the acutely inflamed gallbladder was removed. One stone was impacted in the cystic duct and the common bile duct was normal in size. Convalescence was entirely uneventful.

The patient was well for four weeks and then she began to have pain in the right upper quadrant of the abdomen each day. Because she thought food produced or accentuated the discomfort, the patient was afraid to eat and she lost weight. She did not have fever, chills, nor jaundice. When the attacks of pain became intolerable, the patient reentered the hospital.

Physical examination was entirely negative. Serum bilirubin was 0.24 milligrams percent and the serum anylase was 90 Somogyi units. Intravenous cholangio-

Fig. 2—T-tube cholangiogram which shows duodenal diverticulum filled with dye.

Fig. 3—(Case 2) Duodenal diverticulum shown in upper gastrointestinal roentgen study.

grams revealed slight dilatation of the common bile duct but there was no evidence of any obstruction or calculus. Roentgen examination of the upper gastrointestinal tract disclosed a duodenal diverticulum of moderate size which arose from the second portion of the duodenum (Figure 1).

At operation the common bile duct was dilated, and measured one centimeter in diameter. On opening the duct sandy material escaped, and on exploration of the duct scoops were passed easily into the duodenum. When a T-tube cholangiogram was made the dye passed into the duodenum promptly and the large duodenal diverticulum was filled (Figure 2).

After the diverticulum was exposed by reflecting the duodenum medially, the neck was found to be adjacent to the point at which the common duct entered the duodenum. The diverticulum was excised and the defect in the duodenal wall was closed with two rows of sutures. The T-tube cholangiogram was then normal.

The patient had an uneventful convalescense and she had no further discomfort in the upper abdomen.

Case 2

This patient was a white woman, age 74 years, whose gallbladder had been removed in 1963 because of acute cholecystitis. She remained well until February 1968 when there was onset of upper abdominal pain accom-

Fig. 4—(Case 2) T-tube cholangiogram after removal of the duodenal diverticulum. The common duct was dilated by obstruction caused by diverticulum.

panied by jaundice. The patient was icteric and there was mild tenderness in the right upper quadrant of the abdomen. The results of the pertinent laboratory tests were: Serum bilirubin 5.61 milligrams percent, leukocyte count of 9,900 per cubic millimeter, hemoglobin 14.7 grams, and erythrocyte sedimentation rate 24 millimeters per hour. On examination of the upper gastrointestinal tract a diverticulum was noted in the second portion of the duodenum (Figure 3). Prompt recovery followed institution of medical treatment.

In November, 1968, this woman was again hospitalized because of pain and jaundice. The urine contained two plus bile. The serum bilirubin was 4.4 milligrams percent and declined to 2.2 milligrams percent on November 18. The leukocyte count was 7,400 per cubic millimeter; the sedimentation rate was 24 millimeters per hour. Radiographic examination again showed the duodenal diverticulum which had become larger. Operation was deferred until the patient recovered from a respiratoy infection.

The abdomen was entered through the old upper right rectus scar in December, 1968. The common bile duct was greatly dilated and bile gushed out when the duct was incised. Exploration of the duct did not yield a stone and scoops were passed into the duodenum. The duodenum was reflected medially and an incision was made into it just beyond the pylorus. As the diverticulum was mobilized, putty-like material escaped from it into the duodenum. The opening of the diverticulum was within one centimeter of the ampulla of Vater which was identified and protected by a probe which had been passed down the common bile duct.

After the diverticulum was excised the defect in the duodenum was closed with two rows of sutures. The duodenotomy was extended across the pylorus into the stomach and closed transversely as a pyloroplasty. A T-tube was placed in the common duct and the incision in the duct was snugly closed around the tube. The T-tube cholangiogram did not show any abnormalities except dilation of the biliary tree (Figure 4).

The patient has been well and has had no more attacks of pain.

Summary

Duodenal diverticula are seen in one to six percent of x-ray examinations of the upper gastrointestinal tract. Although most diverticula are asymptomatic and are of no clinical significance, ulceration, perforation, hemorrhage, and enterolith formation may occur and produce symptoms. One of the rarest complications is obstruction of the common bile duct. Two patients whose attacks of pain in the upper abdomen were produced by common bile duct obstruction and whose symptoms were relieved by excision of the diverticula have been described.

Anaphylactoid Purpura with Spontaneous Intestinal Perforation

WILLIAM C. DeWOLF, M.D.

SPONTANEOUS INTESTINAL perforation associated with anaphylactoid purpura is rare; only eleven cases have been reported in the world's literature.[1-7] Herein is presented the third reported survival of such a catastrophe.

Case Report

A five-year-old boy was well until three weeks prior to admission when he suddenly developed a purpuric rash, pedal and scrotal edema, and a fever of 101°F. The patient's past history was negative except for an episode of pharyngitis ten days prior to admission. He was admitted to another hospital where a diagnosis of anaphylactoid purpura was made. A course of steroid therapy was instituted and the patient sent home asymptomatic. Approximately one week later he noted the onset of nausea and vomiting and was admitted to this hospital. The vital signs were normal. The patient was somewhat dehydrated with a purpuric rash over the buttocks and distal lower extremities. There was mild diffuse abdominal tenderness. However the patient complained of no abdominal pain.

The initial laboratory data included a normal coagulation profile. Other values included: Hemoglobin 9.6 grams %, hematocrit 28%, white count 20,800 mm^3, BUN 24 mg %, ASO 166 Todd Units. Abdominal roentgenograms revealed a gas pattern compatible with a mid small bowel ileus. The patient had a small amount of hematemesis and hematochezia. Prednisone was started along with nasogastric suction and the patient improved. Four days later the temperature rose to 104°F, the abdomen became distended and bowel sounds were absent. It was thought that the patient had an intestinal perforation. A celiotomy was performed and the child was found to have an ileal-ileal intussusception with two perforations along the mesenteric border approximately 5 mm in diameter distal to the intussusception. The diseased segment of the ileum, measuring approximately 35 cm, was excised and an end to end anastomosis was made. Pathology Report: The specimen consisted of a segment of ileum. The serosa and mucosal surfaces were hyperemic. There was an intramural hemorrhage and partial sloughing of the mucosa. Here, the bowel was dusky red and the wall filled with blood. There were two dime size perforations through the bowel, located approximately in the middle of the specimen and surrounded by hyperemic mucosa and serosa. Some of the sections showed a great deal of hemorrhage into the wall of the small bowel with necrosis of the wall.

The patient was closed with a gastrostomy and was placed on antibiotics. His postoperative course was uneventful until the fourth day when the child again demonstrated increased abdominal pain with a temperature elevation to 105°F. Blood cultures taken at that time were positive for Klebsiella. Because of the possibility of a third ileal perforation, the child was taken back to the operating room where a second celiotomy was performed. Abdominal exploration was negative. The patient's postoperative course was slow and complicated with a fascial dehiscence of his wound. The patient was finally discharged asymptomatic.

Discussion

Anaphylactoid purpura is primarily a medical disease among children classically associated with the triad of rash, abdominal pain and joint pain. Its exact etiology is unknown although it is believed to represent a hypersensitivity reaction resulting in vascular damage with increased capillary permeability. Localized areas of hemorrhage and edema are produced. Systemic involvement may include mucous membranes, joints, the gastrointestinal tract and the kidneys.

Visceral involvement occurs in about 50-60% of the patients[8] and represents the most acutely serious problems in the management of this disease. Intestinal lesions include areas of subserosal and submucosal hemorrhage and edema which correlates well with the associated signs and symptoms of bleeding, abdominal pain and tenderness. On occasion the edematous hemorrhagic bowel may act as a leading point to initiate intussusception, an uncommon and serious complication of this disease. Rarely, when such involved areas are associated with numerous microthrombi, a localized area of mucosa may slough resulting in ulceration and possible perforation.

The challenge to the surgeon is quite obvious in the treatment of this disease. Abdominal pain associated with findings compatible of an acute abdomen can provide an irresistible indication for

Dr. DeWolf was in the Department of Surgery, Presbyterian St. Luke's Hospital, Chicago, Illinois. Current address: Department of Surgery Division of Urology, University of Minnesota Health Sciences Center, Minneapolis, Minnesota 55455.

abdominal exploration. Oftentimes it is impossible to differentiate an intestinal hematoma alone from one associated with intussusception or perforation. Each may cause obstruction, a mass, and passage of blood per rectum.

Although the incidence of intussusception and/or perforation is not exactly known, it can be estimated to be exceedingly low. When it occurs it can be fatal unless surgery is performed in time. There can be no disagreement with Wolfson's[9] comment regarding the necessity for early operation: "reviewing all the cases one can only say that a sudden worsening of a purpuric patient by severe colicky abdominal pain and vomiting, by absolute constipation (or passage of bright red blood with fecal material), and by the appearance of an abdominal lump which changes little on repeated examinations should provide a strong indication for laparotomy." The presence of unexplained fever, sudden loss of bowel sounds, free air present on roentgenographic examination and an uncontrollable downhill course all add to the list of indications for supporting prompt surgical intervention.

Summary

A case of anaphylactoid purpura with spontaneous intussusception and intestinal perforation is presented. This presents the twelfth reported case of associated spontaneous perforation with anaphylactoid purpura and the third to survive. Anaphylactoid purpura is an allergic vasculitis which may involve the skin, joints, gastrointestinal tract and the kidneys. Abdominal symptoms closely mimic an acute abdomen which may indeed occur in rare instances. In such cases early operation is imperative.

Doctor Wilkinson rearranged his room, as was his habit a dozen times in the day. He laid out his large *Quain's Dictionary of Medicine* in the forefront of the table, so as to impress the casual patient that he had ever the best authorities at his elbow. Then he cleared all the little instruments out of his pocket case—the scissors, the forceps, the bistouries, the lancets—and he laid them all out beside the stethoscope, to make as good a show as possible. His ledger, day-book, and visiting-book were spread in front of him. There was no entry in any of them yet, but it would not look well to have the covers too glossy and new, so he rubbed them together, and daubed ink over them. Neither would it be well that any patient should observe that his name was the first in the book, so he filled up the first page of each with notes of imaginary visits paid to nameless patients during the last three weeks. Having done all this, he rested his head upon his hands and relapsed into the terrible occupation of waiting.*

Nontraumatic Removal of Foreign Bodies

from the Nose and Ears of Infants and Children

RICHARD P. VIRNIG, M.D.

A DIFFICULT AND traumatic ordeal for parent, patient and physician is the removal of a foreign body from the nose or ear canal of an infant or child. Some of the common foreign bodies which have been inserted into their noses and ears by children are: corn, dried field corn or cooked niblets, soy beans, folded bits of paper, small toys and jewelry, especially earrings and sets that have come out of rings.

Admission of the child with a foreign body in the nose and ear to the hospital, administration of a general anesthetic, and removal of the foreign body by irrigation or gentle manipulation is an acceptable method of treatment. This is expensive and inconvenient, and the administration of an anesthetic is not innocuous. The foreign body may be aspirated into the trachea.

A method of extracting foreign bodies from the ear or nose which can be done at once, in the doctor's office, without anesthesia, without risk, and with little discomfort, is my preference. When it has been determined that there is a foreign body in the ear or nose of a child, the child is well restrained with velcro straps or a sheet which immobilizes the arms and legs. A nurse then holds the patient firmly. A Fogarty biliary catheter is tested to determine the amount of air necessary for satisfactory inflation of the balloon and a 2 cc plastic syringe is attached to the catheter. The tip of the catheter is then passed beyond the foreign body, the balloon is inflated and the catheter and foreign body are withdrawn.

For foreign bodies in the nose the catheter is passed along the floor of the nostril and the balloon is inflated, if it is beyond the foreign body. For foreign bodies in the ear the same procedure is followed. If the foreign body is corn or a bean or pea, it has probably swollen, but with care and patience the catheter can be passed and the foreign body removed.

I have used this procedure on numerous occasions and many types of foreign bodies have been successfully removed in this simple manner without anesthesia. In some instances multiple foreign bodies have been found, so it is advisable to examine the nose or ear after recovering the first body. A three-year-old girl was brought to the Clinic because of foul breath. Examination of the mouth and throat revealed no abnormalities. There was considerable discharge from the right nostril and a piece of folded paper, which measured 2x3 inches when unfolded, was removed. Further examination with the speculum showed another piece of folded paper.

A recent case was an eighteen-month-old boy who had been served niblet corn for supper. The mother saw the child push a niblet of corn into the right nostril and attempts to retrieve it were unsuccessful. In the hospital emergency room the niblet of cooked corn was easily removed with the biliary balloon catheter. Another niblet was found higher in the nostril and this, too, was removed with the catheter.

Summary

Foreign bodies in the nose and ears of children can be removed by passing the Fogarty biliary catheter beyond the foreign body, inflating the balloon and withdrawing the inflated balloon and foreign body. Hospitalization and anesthesia are not necessary. Multiple foreign bodies are sometimes present and should not be overlooked.

Wells, Minnesota.

Historic Hospitals

The New York Hospital, 1771-1971

The New York Hospital, its first building facing east toward Broadway, as it appeared about 1811. Courtesy National Library of Medicine, Bethesda, Maryland.

Last year the New York Hospital observed the two hundredth anniversary of its foundation. Its royal charter, granted by King George III, established "The Society of the Hospital in the City of New York in America" on June 13, 1771.

The hospital has encountered adversity in its building projects. The first building burned to its stone foundation before completion. The rebuilding was interrupted by the Revolutionary War, the uncompleted structure being used as barracks for Continental troops and later for Hessian soldiers after the city was occupied by the British. The famous "Doctors Mob Riot," sparked by public indignation at dissection of cadavers (and by grave robbing), began at the hospital in 1788 where the teaching of anatomy was already under way. Not until 1791, twenty years after the beginning, was the hospital ready to receive patients.

The third and present building, which houses the New York Hospital-Cornell Medical Center along York Avenue from Sixty-eighth to Seventy-first Streets, was under construction at the time of the stock market crash in 1929. The hospital's investments had to be liquidated at low prices, the number of beds reduced, and equipment temporarily omitted on several floors.

In spite of these and other hardships the New York Hospital has contributed importantly to patient care, medical teaching, and medical research. The hospital pharmacopoeia built up by its early apothocaries served as a basis for, and ultimately became a part of the U. S. Pharmacopoeia of today. During the Civil War the hospital treated nearly three thousand soldiers under contract with the Federal Government. In 1927 it entered into an agreement of organic association with Cornell University, becoming a primary teaching hospital.

Although a charity hospital in the beginning, it early accepted private patients, first providing private rooms about 1858. Gradually the proportion of private patients has increased to the present day when health insurance and government programs are beginning to obscure the distinction.

Warren L. Kump, M.D.
Minneapolis, Minnesota

Larrabee, Eric: The Benevolent and Necessary Institution, Doubleday & Co., 1971.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

Indications: Upper respiratory congestion and hypersecretion associated with: the common cold; acute and chronic sinusitis; vasomotor rhinitis; allergic rhinitis (hay fever, "rose fever," etc.).

Contraindications: Hypersensitivity to any component; concurrent MAO inhibitor therapy; severe hypertension; bronchial asthma; coronary artery disease; stenosing peptic ulcer; pyloroduodenal or bladder neck obstruction. Children under 6.

Warnings: Advise vehicle or machine operators of possible drowsiness. Warn patients of possible additive effects with alcohol and other CNS depressants.

Usage in Pregnancy: In pregnancy, nursing mothers and women who might bear children, weigh potential benefits against hazards. Inhibition of lactation may occur.

Effect on PBI Determination and I^{131} Uptake: Isopropamide iodide may alter PBI test results and will suppress I^{131} uptake. Substitute thyroid tests unaffected by exogenous iodides.

Precautions: Use cautiously in persons with cardiovascular disease, glaucoma, prostatic hypertrophy, hyperthyroidism.

Adverse Reactions: Drowsiness, excessive dryness of nose, throat or mouth; nervousness; or insomnia. Also, nausea, vomiting, epigastric distress, diarrhea, rash, dizziness, weakness, chest tightness, angina pain, abdominal pain, irritability, palpitation, headache, incoordination, tremor, dysuria, difficulty in urination, thrombocytopenia, leukopenia, convulsions, hypertension, hypotension, anorexia, constipation, visual disturbances, iodine toxicity (acne, parotitis).

Supplied: Bottles of 50 capsules.

SK&F *Smith Kline & French Laboratories*

Trademark

ORNADE® SPANSULE®

brand of sustained release capsules

Each capsule contains 8 mg. of Teldrin®(brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; 2.5 mg. of isopropamide, as the iodide.

UNCOMMON RELIEF FOR COLD SYMPTOMS

If you've seen one, have you really seen them all?

The following patient profiles represent typical clinical situations, but do not necessarily represent actual cases.

Age 22, previously normal me
with occasional menorrhagia.
on a sequential O.C. for four r
Complains of heavy flow,
occasional intracyclic bleedin
edema, tender swollen breast
Indicates estrogen excess.
1st choice: Switch to a com
bination 50-mcg.-estrogen O.C
(such as **Demulen***).

Age 19, small breasts, minor hirsutism, oily hair and skin. History of metrorrhagia, skipped or scanty menses. New user.
Indicates androgenic excess or estrogen deficiency (fertility is suspect).
1st choice: An estrogen-dominant O.C. (such as **Enovid-E***).

Age 25, average frame, poor complexion. No problem with menses, normal para 1. On a low-estrogen/high-progestogen O.C. for two years. Now complains of scanty flow, decreased libido, depression.
Indicates probable buildup of progestogen-related side effects.
1st choice: Switch to a center-spectrum O.C. with more estrogen, less progestational activity (such as **Ovulen***).

Age 21, short, mammose, with normal menses, some acne. Was put on prenuptial regimen of 50-mcg.-estrogen/moderate-progestogen O.C. for two months. Now has increased acne.
Indicates metabolic production of androgen or relative estrogen deficiency.
1st choice: Switch to a 100-mcg.-estrogen combination (such as **Enovid-E*** or a sequential).

Unmasked, physiologically and anatomically, they're not all the same. A basic difference lies in their hormone profiles. One may secrete too much estrogen, another not enough...or perhaps too much androgen; the vast majority would fit somewhere into the broad center spectrum.

Although the profiles described below may not be completely predictive, in optimal O.C. selection, the estrogen-progestogen activity ratio should be carefully matched to the patient profile. Searle offers you O.C.s in a range not only suitable for your patients in the balanced center spectrum, but also adaptable to the patient with another type of hormone profile.

Oral contraceptives are complex medications. Among the commonly reported adverse reactions are: intracycle bleeding, fluid retention, tender or swollen breasts, exacerbation of acne condition, changes in libido, amenorrhea while on medication and upon discontinuance, nausea, leg cramps, headaches, weight gain. Therefore, after reference to the prescribing information, oral contraceptives should be prescribed with care.

*Note: In some patients any level of exogenous estrogen or progestogen may produce symptoms of excess hormone activity.

A 25, tall, slender, athletic, w flat chest. On a progestogen- minant 50-mcg.-estrogen O.C. H recurrent trichomoniasis a Monilia.
ndicates estrogen deficiency and e ess of progestogen in current O.C.
st choice: Switch to a com- b tion pill with 100 mcg. e ogen and less progestational a vity (such as **Enovid-E*** or len or a sequential).

Age 23, "Miss America" figure, previously normal menses, healthy skin and hair. On a 50-mcg.-estrogen pill for four months. Complains of intracyclic bleeding.
Indicates probable need for more estrogen.
1st choice: Switch to a center-spectrum O.C. with more estrogen and moderate progestogen dominance (such as **Ovulen***).

Age 21, college senior, average build. On highly progestogen-dominant/low-dose-estrogen O.C. for six months. Now complains of amenorrhea, between-cycle headaches, weight gain.
Indicates probable progestogen excess.
1st choice: Switch to a center-spectrum pill (such as **Ovulen***).

Age 27, slightly overweight, multiparous. Nausea with all three pregnancies and with a sequential O.C. three years ago. Has pre-menstrual fluid retention and leg cramps.
Indicates probable excess of estrogen.
1st choice: A 50-mcg.-estrogen/progestogen-dominant pill (such as **Demulen***).

Ovulen® a balanced center-spectrum O.C. for most

Each white tablet contains ethynodiol diacetate 1 mg./mestranol 0.1 mg.

Demulen® a moderately progestogen-dominant O.C. for many

Each white tablet contains ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.
Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.
Both Ovulen and Demulen are available in 21- and 28-pill schedules.

a family of O.C. products to help you match the right pill to the right patient

Ovulen®

Each white tablet contains
ethynodiol diacetate 1 mg / mestranol 0.1 mg.

Demulen®

Each white tablet contains
ethynodiol diacetate 1 mg / ethinyl estradiol 50 mcg.

Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.

Actions – Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note – Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication – Ovulen and Demulen are indicated for oral contraception.

Contraindications – Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings – The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain[1-3] leading to this conclusion, and one[4] in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll[3] was about sevenfold, while Sartwell and associates[4] in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions – The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any poss influence of prolonged Ovulen or Demulen therapy on pituitary, ovarian, adre hepatic or uterine function awaits further study. A decrease in glucose tolera has been observed in a significant percentage of patients on oral contra tives. The mechanism of this decrease is obscure. For this reason, diabetic tients should be carefully observed while receiving Ovulen or Demulen ther The age of the patient constitutes no absolute limiting factor, although treatm with Ovulen or Demulen may mask the onset of the climacteric. The patholo should be advised of Ovulen or Demulen therapy when relevant specimens submitted. Susceptible women may experience an increase in blood pres following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives – A statistically significant association has been demonstrated betw use of oral contraceptives and the following serious adverse reactions: throm phlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, such a relat ship has been neither confirmed nor refuted for the following serious adve reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdo inal cramps and bloating), breakthrough bleeding, spotting, change in menstr flow, amenorrhea during and after treatment, edema, chloasma or melas breast changes (tenderness, enlargement and secretion), change in we (increase or decrease), changes in cervical erosion and cervical secretions, s pression of lactation when given immediately post partum, cholestatic jaund migraine, rash (allergic), rise in blood pressure in susceptible individuals a mental depression.

Although the following adverse reactions have been reported in users oral contraceptives, an association has been neither confirmed nor refut anovulation post treatment, premenstrual-like syndrome, changes in libi changes in appetite, cystitis-like syndrome, headache, nervousness, di ness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforr erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral cont ceptives: hepatic function: increased sulfobromophthalein retention and otl tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and thyroid function: increase in PBI and butanol extractable protein bound iodi and decrease in T^3 uptake values, metyrapone test and pregnanediol det mination.

Regionalization in Minnesota

With this issue subscribers to Minnesota Medicine receive a supplement containing ten reports on activities supported by Northlands Regional Medical Program, Inc. (NRMP). It has been a rewarding experience to serve as "Guest Editor" for this supplement and write the lead article. In line with early NRMP program emphasis, the articles deal with multiple facets of continuing education for health-related personnel and education of patients and their families. Included are physicians, nurses, nutritionists, laboratory technicians, social workers, hospital administrators, clergymen, patients and the families of patients. The authors write about key health care issues, problems and barriers. These matters not only provide interesting reading but demonstrate the scope of continuing education problems and document various innovative methods.

Special editorials included in this issue provide a form of recognition for the two medical leaders who conceived Northlands Regional Medical Program back in 1965—Dr. Robert B. Howard and Dr. J. Minott Stickney. As Dean of the College of Medical Sciences and President of the Minnesota State Medical Association respectively, Drs. Howard and Stickney laid the foundation for a democratic organization to develop this new federal-private partnership program. The principles these "founding fathers" built into NRMP enabled this initially controversial program to withstand the series of crises of any new movement and emerge stronger for the experience. In this program, as in many others, these esteemed Minnesota physicians inspired many others to high standards of achievements. It is a pleasure to have the opportunity to give them a token of recognition which they so justly deserve.

NRMP is a part of a growing movement in applied research and development. Those of us who witnessed the transition of fundamental research from a labor of love to a public movement have sincere hopes that the current applied research movement can become equally productive. The great challenge of technological discovery is being followed by the equally great challenge of scientific application of new discoveries for the betterment of the whole society.

Future articles in this and other journals will report on currently active projects in areas of Health Manpower and Health Services Development, as well as Education. The regionalization movement seems to have caught on, and participants throughout the state are utilizing rational scientific methods in seeking solutions to our complex health care problems. The persistent "Ferment in Medicine" described so lucidly by Dr. Richard Magraw in 1966 is evolving into a progressive force for constructive change in the health care system in Minnesota.

Winston R. Miller, M.D.
Guest Editor

Dr. Miller is the Program Director, Northlands Regional Medical Program, Inc., St. Paul.

DOCTORS.

Is your investment portfolio suffering from one of these diseases?

1. Piecemealitis.

A common disorder characterized by fragmented investing — buying a little bit here, a little bit there; usually the result of simple disorientation on the part of the investor.

2. Hot-tip-a-mania.

A compulsive, devil-may-care disease; usually manifests itself following phone calls from friends about "hot" investment tips; generally communicated orally.

3. Apartmenthousitoma.

An affliction which commonly strikes those in the medical profession who are attracted to get-rich-quick real estate ventures; can cause great financial pain and mental anguish, especially in a market that's overbuilt.

4. Multiple brokerosis.

A state of investment confusion which results from dealing with too many different counselors; characterized by the left hand not knowing what the right hand is doing.

5. Simple neglect.

A minor failing which, if not dealt with, can develop into a critical disorder; caused by not having enough time to care for investments properly; common not only to physicians, but to dentists, lawyers and most highly-paid business executives, as well.

What's the cure?

If you have an investment portfolio with $50,000 or more in securities, and you have the slightest fear that it's suffering from any of the above diseases, we strongly urge you to consult a Professional Investment Adviser at Northwestern/St. Paul.

We know all about diseases like that. And how to cure them.

In fact, we specialize in working for busy professional men who want to get and keep their investment portfolio on the road to good health.

We'll do the same for you, for as little as $300 per year (or less than 1% of the amount of your total investments).

Our credentials.

The people on our staff are all highly-trained, experienced specialists. In stocks. Bonds. Income. Gains. Taxes. The entire investment field.

When they go to work on an investment problem, they don't make top-of-the-head diagnoses.

They deal with facts. Proven facts. Facts gained from research (something we believe in).

So, they won't promise you any get-rich-quick "miracles". But they will offer you the prospect of good, steady, dependable, healthy growth.

Last year, in fact, a national professional journal* ranked our bank's investment performance among the top ten banks in the entire nation.

Want to learn more?

Why not bring in your investment portfolio for a financial checkup?

One of our specialists will give it a thorough examination (in light of your investment goals) and prescribe whatever he feels is necessary to put it in tip-top condition.

It won't cost you an arm and a leg. But it could save you thousands of dollars. And provide your investments with a long and prosperous life for the years ahead.

Just fill out the blank below and drop it in the mail.

Your portfolio has nothing to lose.

Except what ails it.

*Details on request

I'd like an appointment.

Please telephone me to set up an appointment for my investment portfolio exam and diagnosis.

NRMP Supplement

THE SUPPLEMENT to this December, 1972 issue of MINNESOTA MEDICINE is a comprehensive report of the activities of the Northlands Regional Medical Program (NRMP). The supplement is dedicated to Mary Jane Ryan, Ph.D., librarian for NRMP, who died this year. Her posthumous article is a lively discussion of hospital and other medical libraries in the State. She describes how physicians, both rural and metropolitan, can use MEDLARS and the new MEDLINES to search medical literature.

Winston Miller, the first director of NRMP, discusses its accomplishments in the five years Northlands has been in existence.

Russell Lucas records a dialogue with his good friend, Sir William Osler.

William R. Fifer points out how a medical audit can be conducted in a community hospital; how it can lead to better medical care by exposing deficiencies to the medical staff willing to let itself be audited.

NRMP came into being during the early development of intensive coronary care units (ICCU) and supported their development and training of personnel to man them. O'Donovan, Mankin et al. describe the mortality of acute myocardial infarctions in the ICCU's as subsiding from 30 to 35% to 22%, a decrease largely due to better care in the earliest hours after the attack. This is a major therapeutic advance.

The RMP concept and its local deployment as the local NRMP as described in the supplement undoubtedly will be enthusiastically commended by many and probably just as enthusiastically condemned by some. All physicians, however, should become acquainted with the activities of this organization.

Reuben Berman, M.D.
Editor

*Supplements are supported by special funds and are printed at no expense to MINNESOTA MEDICINE or the Minnesota State Medical Association.

Historical Development of NRMP

REGIONAL MEDICAL PROGRAMS had their origin under Public Law 89-239. The 89th Congress in 1965 will long be remembered for the legislation affecting the medical profession. It established Medicare and Comprehensive Health Planning in addition to Regional Medical Programs. RMP provided for cooperative relationships between the practicing medical profession and the centers of medical education. The general objective was to bring the latest and best in medical knowledge to the health care delivery system and education was to be an essential ingredient. Because of the impetus from Dean Robert Howard of the University of Minnesota Medical School, an appropriate planning group was gathered together. With great foresight he insisted that the management of the Regional Medical Program should reside outside the two medical schools then in existence; namely, the University of Minnesota College of Medical Science and the Mayo Graduate School of Medicine. In view of the subsequent shift in emphasis from education to health care delivery, the new corporate structure formed by representatives of major medical institutions proved to be very appropriate. Special thanks are due to the University of Minnesota which made funds available before grant monies were obtained, to the Minnesota State Medical Association for making its charitable foundation the original grantee, and to the Mayo Foundation for directing the fiscal affairs for the medical society's foundation in an interim period before a new corporation could be formed. Nine sponsoring institutions provided necessary financial guarantees for the new organization named Northlands Regional Medical Program, Inc.

Those of us who participated in the birth of Northlands Regional Medical Program have often been asked about the selection of the name. The original legislation and subsequent regulations suggested that natural areas of education and practice should prevail and that state lines were not to be rigid boundaries. The name "Northlands" was selected to denote a broad area of

coverage. Later experience showed that each state wished to have its own Regional Medical Program, and Northlands has been primarily a Minnesota activity. However, our neighbors have been flexible enough to cooperate in some truly regional thinking.

In October, 1967, Dr. Winston R. Miller was appointed to the position of director. He brought an unusual combination of insight and skill to the program. With a background of teaching at the University of Kansas, private practice in Red Wing, Minnesota, and as medical director of the St. Paul Medical Center, Inc. and Director of Medical Education at Miller Hospital in St. Paul, he has been cognizant of the problems in the complex relationships of practicing physicians to the education and health care delivery systems. It is not surprising that he has been recognized by the National Regional Medical Programs as an outstanding leader. Ably assisted by Mr. Robert Wilkins who came from the field of hospital administration, Dr. Miller has assembled an excellent staff. The articles which appear in this Supplement to MINNESOTA MEDICINE demonstrate some of the results of their work.

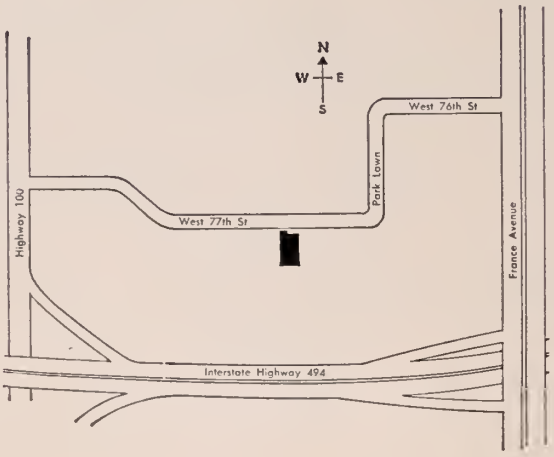
Regional Medical Programs like other government enterprises recognize the expanding role of the consumer. Those of us who have had the privilege of working with the Regional Advisory Group in which consumers play an important part have had a new and gratifying experience. We are especially grateful to Judge Stephen L. Maxwell of the District Court in St. Paul for his leadership of the Advisory Group during the formative period.

Dr. Miller and Mr. Wilkins with the rest of the staff have fostered the concept that the Regional Medical Program offers an opportunity for the private sector supported by public funds to pursue the goal of bringing improved health care to the citizens of Minnesota. Many in the medical profession (as well as others) originally adopted a watchdog attitude which has now given way to a sense of partnership in innovative studies and activities. With the decision by the Nixon administration to support Regional Programs as a significant part of its approach to the solution of health care problems, all segments in Minnesota, public and private, should be prepared to participate in order to insure the viability of Northlands Regional Medical Program. Sound cooperative efforts by the diverse elements in our health care delivery system are necessary and desirable. Inevitably, there will be more regionalized activity because of the distribution pattern of physicians, the cost of hospital facilities and modern communication methods. Efforts toward such regionalization come in many ways from a variety of sources. Northlands Regional Medical Program has made a significant contribution to the process. It has been both an originator and a catalytic agent.

J. M. Stickney, M.D.
Rochester, Minnesota

Northlands Regional Medical Program, Inc.

I AM GRATEFUL for the opportunity to comment and to participate in this special issue of MINNESOTA MEDICINE, which comprises a timely report on the activities of the Northlands Regional Medical Program (NRMP). In its seven-year history NRMP has made great strides and has many major accomplishments to its credit. The articles in the accompanying supplement, while reporting only a fraction of the activities of NRMP, give ample testimony to the imaginativeness and vigor with which its goals have been pursued by an able staff and by a host of health workers in various cooperating agencies.



Seven years is surely but a brief segment in the span on our nation's history. It is difficult to realize that so many changes have taken place in so many areas of American life, including health care, during this short period. In the mid-1960s, the public was just beginning to come to an understanding of the seriousness of the shortage and maldistribution of physicians and other health care workers. Further, there was a growing realization that biomedical research alone had not resolved the health care problems of the nation. Despite the notable advances that had been made in understanding biologic phenomena, the fruits of post-World War II research had not effectively been passed on to the average citizen.

Against this backdrop came the report from President Johnson's National Commission—often

INBORN HEART DEFECTS

®

known, for its chairman, as the DeBakey Commission—recommending "A National Program to Conquer Heart Disease, Cancer and Stroke," containing recommendations for the establishment of a series of centers across the nation which would study and treat these disorders. Almost immediately there was substantial concern and attendant opposition from many sources. The medical academic community envisioned the proposed Regional Medical Program (RMP) as a threat to the support of fundamental research. Many practicing physicians saw in it an attempt to replace the existing patterns of medical practice with new agencies that would be government-dominated or government-operated. All physicians and a good many knowledgeable lay people were concerned about a program focusing on heart disease, cancer, and stroke to the apparent exclusion of concern for other kinds of disease that can be equally devastating in their impact.

The final legislation establishing the regional medical program, as passed by both Houses of Congress and signed into law by the President, significantly softened the report of the Commission with respect to the development of treatment centers that might affect patterns of medical practice. The thrust of the legislation was to emphasize the educational and coordinating roles of RMP. The law specifically provided that RMPs should include as key constituents any academic health centers located within their respective jurisdictions.

The leaders of the University of Minnesota College of Medical Sciences and those of the Mayo Institutions joined in sponsoring an organizational meeting to which the officers or other leaders of the other major health care agencies and associations within the state were invited. Early meetings dealt in large measure with organizational concerns and with defining the potential role or roles of the RMP. Not surprisingly, the participating agencies from time to time evidenced concern that the new agency might interfere with or adversely affect their respective functionings. Even in early meetings, however, it was evident that the RMP had become a mechanism whereby, for the first time, agencies with substantial responsibility for the health care of the people in our area were communicating with one another and were discussing at least the possibility of joint action to meet problems of common concern.

The original organizing group was broadened to become even more representative. As mutual confidence grew among members of the group, less time was spent in parochial concern and more time in effective planning for the sound development of an RMP. A program director was subsequently appointed, and this proved to be a happy choice indeed. The Northlands Regional Medical Program has had sound direction by its board and very able administration by Dr. Miller and his staff. As the accompanying supplement records the fact that NRMP has been deeply involved in projects relating to both professional and lay education, others related to the development of health manpower, and still others related quite directly to the provision of health services. Further, NRMP has joined in the sponsorship of both planning and operational projects carried out by other health agencies. At the present time, it is safe to say, any major health care development in the State of Minnesota would necessarily have the active participation of NRMP.

NRMP can look back on a productive and exciting seven years. More importantly, it can look forward to opportunities for even greater accomplishment during the coming years. I am proud to have been among those responsible for giving original impetus to the development of NRMP and for the selection of its director.

Robert B. Howard, M.D.
Minneapolis, Minnesota

I believe when you are in any contest you should work like there is—to the very last minute—a chance to lose it. This is battle, this is politics, this is anything.—Dwight D. Eisenhower

---

Jest breaks no bones.—Samuel Johnson, quoted in Boswell's Life of Johnson.

Respiratory Distress Syndrome

WHEN NEONATAL MORTALITY rates of the United States are compared to many other countries, it would appear that our citizens are receiving second class care. Dr. Martha Burke-Strickland* has pointed the way to improve on these figures. The principal caues of death in the newborn period is respiratory distress syndrome. The infant at risk can be identified and a good result achieved by immediate and adequate treatment. There are however, several road blocks.

One of the frustrations of the busy pediatrician is lack of communication with the equally busy obstetrician. However if these babies at high risk are to be saved, there must be more coordination of effort to reduce this risk. If the amniotic fluid predicts a RDS potential, the pediatrician should be notified so that he can be available to initiate the preventive care as outlined by Dr. Burke-Strickland.

It has been stated that the high neonatal mortality rate in the United States is a social rather than a medical problem. Because of high medical costs and a shortage of medical personnel, optimal care is not achieved.

Many medical insurance policies do not adequately cover the care of the newborn. The high cost of the optimal care may bankrupt the young couple starting out life with meager financial resources.

Recently Dr. Jay Arena, President of the American Academy of Pediatrics, testifying before a U.S. Senate Appropriations Sub-committee, stated "The $900,000 the Department of Health, Education and Welfare will spend for Newborn Intensive Care Units in the fiscal year 1973 is not even enough money to build one mile of interstate highway." These units are costly to build, equip and run. Arena recommended an increased appropriation of $5,000,000. The newborn intensive care unit may not only save a life, but a lifetime.

C. Sherman Hoyt, M.D.
Minneapolis, Minnesota

*Burke-Strickland, Martha: Preventive aspects of respiratory distress syndrome. Minnesota Med 55:9:792, 1972.

Children's Reactions to Hospitalization

WHILE CHILDREN MAY vary in the condition that brings about hospitalization, they all share in the emotional reaction to the experience. All too frequently this reaction is moved to a place of secondary importance in our management of the medical condition. The child's reaction is generally of importance only if there is bothersome behavior to deal with. The quiet or compliant child who is not a management problem does have some feelings about his hospitalization. The noisy or crying child merits consideration over and above our frustration level. Parents in attendance might be more than a bother, though they interfere with the orderly discharge of nursing routines.

Duffy* outlines the scope of the problem and calls it to our attention. I would hope that future articles bring the day-by-day solutions of this problem. We can start now by becoming more aware of the feelings of our young charges. To do this, we have to listen to him.

In a large, modern orthopedic hospital in the East, I was called to see a young boy of 10 who was apathetic and unresponsive to the staff. He had been called into the hospital some days in advance of his surgical procedure, but encountered a delay due to scheduling difficulties. He was observed by the nursing staff to be more and more unresponsive to life around him. A conversation with him rapidly established his perception that he had been left off by his family, was told that he would be *put to sleep* and that his knee would be "fixed." He apparently stopped listening at the "put to sleep" portion of the explanation. (He had a sister who had recently died of a heart condition in her sleep.) On the ward, he saw his roommates one by one placed on carts and whisked off. They did not return. He did not know that the hospital routine was to house postsurgical patients in a recovery area. Therapy for this young man consisted of loading him in a wheelchair to visit the recovery ward where he could establish for himself the reality that his recent friends were alive and in different stages of being well. In like fashion, I found that the patients were acutely aware of the prognosis and progress of fatal illnesses, though they observed *our* rule that they were topics "not to be discussed." Duffy reminds us to engage in the primary prevention of possible emotional difficulties. This is something we can start now.

Ronald Kyllonen, M.D.
Minneapolis, Minnesota

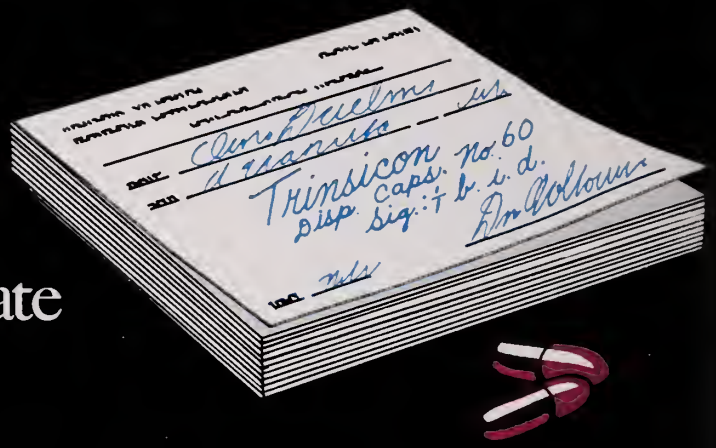
Iron therapy for anemia is almost as old as history itself

Celsus's empirical use of iron

Aulus Cornelius Celsus recommended an unusual form of iron therapy for the treatment of enlarged spleens—the oral administration of water that blacksmiths had used for dousing white-hot iron.



For more modern anemia therapy

Trinsicon®

Hematinic Concentrate with Intrinsic Factor

(See reverse side for prescribing information.)

Trinsicon®
Hematinic Concentrate with Intrinsic Factor

Description: Each Pulvule® contains—

Special Liver-Stomach Concentrate, Lilly (containing Intrinsic Factor)	240 mg.
Cobalamin Concentrate, N.F., equivalent to Cobalamin	7.5 mcg.
(The total vitamin B_{12} activity in the Special Liver-Stomach Concentrate, Lilly, and the Cobalamin Concentrate, N.F., is 15 micrograms.)	
Iron, Elemental (as Ferrous Fumarate)	110 mg.
Ascorbic Acid (Vitamin C)	75 mg.
Folic Acid	0.5 mg.

Indications: Trinsicon is a multifactor preparation effective in the treatment of anemias that respond to oral hematinics, including pernicious anemia and other megaloblastic anemias and also iron-deficiency anemia. Therapeutic quantities of hematopoietic factors that are known to be important are present in the recommended daily dose.

Vitamin B_{12} with Intrinsic Factor—When secretion of intrinsic factor in gastric juice is inadequate or absent (e.g., in Addisonian pernicious anemia or after gastrectomy), vitamin B_{12} in physiological doses is absorbed poorly, if at all. The resulting deficiency of vitamin B_{12} leads to the clinical manifestations of pernicious anemia. Similar megaloblastic anemias may develop in fish tapeworm (*Diphyllobothrium latum*) infection or after a surgically created small-bowel blind loop; in these situations, treatment requires freeing the host of the parasites or bacteria which appear to compete for the available vitamin B_{12}. Strict vegetarianism and malabsorption syndromes may also lead to vitamin B_{12} deficiency. In the latter case, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient.

Potency of intrinsic factor concentrates is determined physiologically, i.e., by their use in patients with pernicious anemia. The liver-stomach concentrate with intrinsic factor and the vitamin B_{12} contained in two Pulvules Trinsicon provide 1½ times the minimum amount of therapeutic agent which, when given daily in an uncomplicated case of pernicious anemia, will produce a satisfactory reticulocyte response and relief of anemia and symptoms.

Concentrates of intrinsic factor derived from hog gastric, pyloric, and duodenal mucosa have been used successfully in patients who lack intrinsic factor. For example, Fouts *et al.* maintained patients with pernicious anemia in clinical remission with oral therapy (liver extracts or intrinsic factor concentrate with vitamin B_{12}) for as long as twenty-nine years.

After total gastrectomy, Ficarra found multifactor preparations taken orally to be "just as effective in maintaining blood levels as any medication that has to be administered parenterally." His study was based on twenty-four patients who had survived for five years after total gastrectomy for cancer and who had been taking two Pulvules Trinsicon daily.

Folic Acid—Folic acid deficiency is the immediate cause of most, if not all, cases of nutritional megaloblastic anemia and of the megaloblastic anemias of pregnancy and infancy; usually, it is also at least partially responsible for the megaloblastic anemias of malabsorption syndromes, e.g., tropical and nontropical sprue.

It is apparent that in vitamin B_{12} deficiency (e.g., pernicious anemia), lack of this vitamin results in impaired utilization of folic acid. There are other evidences of the close folic acid-vitamin B_{12} interrelationship: (1) B_{12} influences the storage, absorption, and utilization of folic acid, and (2), as a deficiency of B_{12} progresses, the requirement for folic acid increases. However, folic acid does not change the requirement for vitamin B_{12}.

Iron—A very common anemia is that due to iron deficiency. In most cases, the response to iron salts is prompt, safe, and predictable. Within limits, the response is quicker and more certain to large doses of iron than to small doses.

Each Pulvule Trinsicon furnishes 110 mg. of elemental iron (as ferrous fumarate) to provide a maximum response.

Ascorbic Acid—Vitamin C plays a role in anemia therapy. It augments the conversion of folic acid to its active form, folinic acid. In addition, ascorbic acid promotes the reduction of ferric iron in food to the more readily absorbed ferrous form. Severe and prolonged vitamin C deficiency is associated with an anemia which is usually hypochromic but occasionally megaloblastic in type.

Contraindications and Precautions: Anemia is a manifestation that requires appropriate investigation to determine its cause or causes.

Folic acid *alone* is unwarranted in the treatment of pure vitamin-B_{12}-deficiency states, such as pernicious anemia. Indeed, the use of folic acid in large doses in pernicious anemia without adequate vitamin B_{12} may result in hematologic remission but neurological progression.

As with all preparations containing intrinsic factor, resistance may develop in some cases of pernicious anemia to the potentiation of absorption of physiological doses of vitamin B_{12}. If resistance occurs, parenteral therapy, or oral therapy with so-called massive doses of vitamin B_{12}, may be necessary for adequate treatment of the patient. No single regimen fits all cases, and the status of the patient observed in follow-up is the final criterion for adequacy of therapy. Periodic clinical and laboratory studies are considered essential and are recommended.

In extremely rare instances, skin rash suggesting allergy has been noted following the oral administration of liver-stomach material. Allergic sensitization has been reported following both oral and parenteral administration of folic acid.

Hemochromatosis and hemosiderosis are contraindications to iron therapy.

Adverse Reactions: In rare instances, iron in therapeutic doses produces gastrointestinal reactions, such as diarrhea or constipation. Reducing the dose and administering it with meals will minimize these effects in the iron-sensitive patient.

Dosage: One Pulvule twice a day. (Two Pulvules daily produce a standard response in the average uncomplicated case of pernicious anemia.)

How Supplied: Pulvules Trinsicon® (hematinic concentrate with intrinsic factor, Lilly), in bottles of 60 and 500 and in Identi-Dose® (unit dose medication, Lilly) in boxes of 100.

Trinsicon®
Hematinic Concentrate with Intrinsic Factor
A Comprehensive Hematinic

Case Report

Intussusception of the Base of the Appendix

ERLING A. KLOPPEDAL, M.D. AND LUIS H. TOLEDO-PEREYRA, M.D.

APPENDICEAL INTUSSUSCEPTION is a rare condition. Only a few cases have been reported in the radiologic[1,3] and surgical literature.[2] Even fewer were those in which the correct diagnosis was made preoperatively.

Two types of appendiceal intussusception may be diagnosed radiologically by means of the barium enema examination[4,5]: (1) complete intussusception of the appendix presenting as a thumb-like mass projecting into the cecum,[6] and (2) partial intussusception of the base of the appendix with or without filling of the appendix by barium. Visualization of the appendix in the latter type is unusual[3] and the case reported below is believed to be only the second published instance of such an occurrence. A third type, in which the appendix intussuscepts into itself, has not been demonstrated radiographically.

The importance of distinguishing a benign cecal lesion from a malignant one is obvious. Included in the differential diagnosis are mucosal, intramural, and extrinsic lesions involving the cecum itself, the appendix, or the ileocecal valve. In most cases direct visualization at surgery will be necessary for diagnosis.

The main predisposing factors in the pathogenesis of intussusception of the base of the appendix are mucocele[7] and foreign body or other conditions that lead to excessive peristalsis of the appendix.

Case Report

A fifty-one year old white male, was admitted to the Veterans Hospital, Minneapolis, with the complaints of abdominal pain, weight loss, food intolerance, and postprandial vomiting. A Billroth II gastrectomy had been performed ten years earlier for duodenal ulcer. Laboratory studies including hemoglobin were within normal limits. An oral cholecystogram showed a single gallstone. Barium enema disclosed a polypoid filling defect in the cecum. A repeat study (Figure 1 and 2) demonstrated association of the defect with the base of the opacified appendix.

At surgery there was an obvious intussusception of the base of the appendix which was easily reduced by manipulation. No other abnormality was found. A simple appendectomy was performed, followed by removal of an elliptical section of the cecum surrounding the base of the appendix. A cholecystectomy was also done. The pathology report indicated cholecystitis with cholelithiasis and a normal appendix and cecum. Recovery from surgery was complete, and the patient's symptoms were relieved.

Dr. Kloppedal is staff radiologist, V.A. Hospital and University of Minnesota, Minneapolis, Minnesota.
Dr. Toledo-Pereyra is resident in surgery, V.A. Hospital and University of Minnesota, Minneapolis, Minnesota.

Fig. 1—Polypoid filling defect in proximal cecum.

Fig. 2—Same defect with the barium-filled appendix. Note the very smooth, symmetrical appearance of the projecting mass, oriented very evenly around the barium-filled appendiceal lumen, fairly certainly ruling out any associated pathology.

Comment

With regard to the surgical treatment of appendiceal intussusception, anything more than simple appendectomy is probably unnecessary. However, some surgeons do recommend anchoring the proximal end of the cecum or the stump of the appendix to surrounding tissues with sutures to prevent future intussusception of the stump and even of the cecum into the ascending colon.

Recently, we learned of two patients with complete invagination of the appendix who were subjected to hemicolectomy because of presumably malignant lesion in the cecum and because of the "no-touch" procedure.[6] It is probable that cecotomy with direct visualization would have led to simple local removal.

In our case the exact preoperative diagnosi was not made initially and hemicolectomy wa considered. A review of the literature, however raised the possibility of a benign intussusceptio of the appendiceal base and resulted in a mor conservative surgical approach.

Summary

Although a rare condition, intussusception o the base of the appendix should be considered i the differential diagnosis of filling defects of th cecum to avoid unnecessary radical surgery. A case is reported in which the anatomy of th lesion was radiographically demonstrated.

A sound discretion is not so much indicated by never making a mistake as by never repeating it.—Bovee

Healthcaremanship

RICHARD L. REECE, M.D.

"Ordinary health, remember, is highly gambit-prone."—Stephen Potter, One-Upsmanship

SHALL BEGIN by distinguishing between Health are and Healthcaremanship.

Health Care is the serious matter of maintaining ealth, preventing disease, treating illness, and eeding convalescence.

Healthcaremanship, on the other hand, is a ord game. Players match words to outwit each ther. The one who writes or talks the most while ying the least wins.

Healthcaremanship requires experience, knowldge, and forensic skill. Furthermore, healthcareanship is important. It will remain so as long as ere are hearings to be heard, grants to be granted, races to be run, funds to be found, speeches be spoken, words to be written, and listeners r readers to boggle or befuddle. Healthcaremanhip is not essential for these activities, but it helps.

General Gambits

Before I get to specifics, a few words about eneral gambits. In an earlier article,* I deined these as they applied to medical writing. Because these gambits work equally well in Healthcaremanship, I shall review them now.

Gambits	Brief Definition
Windfoggery Weave	Weaving together wind and fog on paper
Retrospective Ramble	Exhaustively reviewing your subject by referring to everything previously written on subject
Humble Hedge	Qualifying your meaning into nothingness by appearing to be humbly objective
Passive Ploy	Writing in passive voice in order to place yourself in background and to divest yourself of responsibility
Word Wedge	Wedging impressive words into sentences where they don't belong
"That" Thrust	Thrusting "That" into start of sentences to avoid direct statements or to conceal them
Verb Void	Voiding sentences of verbs by changing them into nouns in order to lengthen sentences without changing their meaning
Double Dawdle	Doubling word volume but keeping facts constant by using two words of same meaning where one would do
Paragraph Parry	Writing long paragraphs by opening with crisp sentence, then taking it all back by redefining and qualifying opening sentence
Finishing Finesse	Summarizing ideas that were never expressed in order to achieve meandering ending

Many Healthcaremen can get by on these gambits alone. But some insist Healthcaremanship is not as simple as medical writing. Perhaps not. Anyway, for those who wish to further develop their skills, I have come up with these gambits.

Saxon Sidestep
Management Maneuver
Computer Connection
Science Screen
Comprehensive Offensive
Buzz Bomb

Saxon Sidestep

Healthcaremanship is a game of fundamentals. And perhaps the most fundamental thing is this: never use a short word where a long one would do. Short words tend to be Anglo-Saxon in origin. They also tend to be direct and to the point. Since the Healthcareman's aim is to impress and not to inform—to occupy space with dignity while adding nothing new—he should sidestep Saxon expressions. Here are examples.

Saxon	Saxon Sidestep	Gain in Space
use	utilization	8 letters
start	implementation	10 letters
nurse	care coordinator	11 letters, one word
hospital	Health and Allied Sciences Center	24 letters, four words

Management Maneuver

This gambit is far more subtle because it rests on a philosophical assumption—that your opponent knows so little about the arcane art of management that you can baffle him with managerial terms. Managers believe this works particularly well on physicians. The physician, it seems, is capable of making decisions about one person. After all, that's what diagnosis and treatment are about. But he can't grasp decisions that involve many people. That's management.

In any event, the Management Maneuver is a variation of the Double Dawdle. You maneuver the situation (a memo, a committee meeting, a speech, a newspaper release) to the point where a decision must be made involving more than one

Dr. Reece is associated with the Metropolitan Medical Center, 900 South Eighth Street, Minneapolis, Minnesota 55404.

*Reece, R. L.: Space-Occupying Gambits for Medical Writers. J Amer Med Assn, 200:56 1967.

person.

Then you drop a pair of managerial words out of the blue. Why a pair? 1. Because two words are always better than one; and 2. Because you must always qualify a noun. Never let a healthcare word stand alone.

Paired Expressions for Management Maneuver Gambit	Noun Alone #Letters	Noun + Qualifier #Letters	% Gain in Space
Feasibility studies	7	17	+143%
Longterm planning	8	16	+100%
Integrated objectives	10	20	+100%
Coordinated resources	9	20	+122%
Systematic analysis	8	20	+150%

Computer Connection

It is always good gamesmanship for the Healthcareman to show that what he's saying has some connection with computers. The reasons are not hard to find. In the first place, not many people know how computers work. Secondly, computer talk is impressive for its own sake. And thirdly, the computer is a logic machine. Therefore, when you use computer words, what you're saying must be logical:

Any of the following words will do (in any combination):

Adjectives	Nouns
Systematized	Systems
Digital	Programs
Programming	Feedback
Cybernetic	Bits
Binary	Memory
Compatible	Interface

Science Screen

As you might guess, the Science Screen is a good deal like the Computer Connection. You simply try to send up a scientific smoke screen so your opponent will not know what you are saying.

I could give you many examples of words that create this effect, but for reasons of space, I'll settle for one: *Parameter.*

Now there, you'll have to admit, is a word with a scientific ring—a word of precision. But no one, fortunately, knows what it means. Look it up in any dictionary (I have), and you'll find it's a mathematical expression meaning a variable constant which varies with the circumstances of its application. A radius, for example, is a parameter of a circle. Vary the size of the circle, and you vary the radius, even though it remains constant in relation to the circle. A scientific word that means a variable constant is an ideal Science Screen. It should keep your opponents going around in circles.

Comprehensive Offensive

This is probably the most powerful single gambit the Healthcareman has at his command. It powerful for three simple reasons: (1) It has emo tional appeal; (2) It puts the opposing player o the defensive; and (3) You rarely have to defir what you mean.

It's also powerful because it's easy to use. Yo simply pick a word that fits the audience you'r addressing (or the opponent you're toying with and attach any of the following comprehensiv adjectives to the term "Health Care."

Universal
International
Nation
Regional
Community
Local
Total
Comprehensive
Complete
Multiphasic
Organized
Individual

Some of the critics of this gambit have rename it the "Illusive All-Inclusive," "Care Dare," o "Health Stealth." But the critics are just upse because of the gameman's offensiveness. Remem ber. There's no defense against a comprehensiv offensive.

Buzz Bomb

The last gambit I shall describe should only b used in desperation, never indiscriminately.

A few years ago, a member of the U. S. De partment of Agriculture, now forgotten but no gone, first described "buzz words." These word served as bureaucratic bombs. If you were cor nered, you dropped three of them in quick succes sion. You simply arrange your favorite words i three columns—two qualifying adjectives and a abstract noun. Then, if anyone asked you ar embarrassing question, you triggered your buz bombs in 1-2-3 order.

Here, to illustrate the point, are three column of Healthcare buzz words.

1	2	3
total	management	care
regional	supportative	coordinator
universal	health	analyses
primary	integrated	centers
comprehensive	ambulatory	services
national	resource	priorities
quality	pilot	planning
interdependent	involvement	needs
preventive	paramedical	studies
systematized	effectiveness	utilization
feasible	digital	implementations
delivery	scientific	objectives
unmet	outreach	systems
community	allied	maintenance
centralized	medical	parameters
longterm	multiphasic	feedback
		crises

How could you use these lists?

Well, if your opponent is pressing, you can uickly drop *one* 1-2-3 combination, e.g.

"Don't you regard *Centralized Health Needs* as ompulsory?"

That qualifies as a single Buzz Bomb.

But if the opponent counters with: "What do ean by *Centralized Health Needs?*, you assert:

"Centralized Health Needs simply represent *ystematized Health Implementation* in order to btain Quality Health Maintenance."

That statement is a triple Buzz Bomb, or a Buzz litz. To put it even more eloquently, you could all it a Healthcare Blitzkrieg.

If you wish to be more discriminating in your ttack, i.e. to drop "smart" buzz bombs, you may o so far as to define what you mean.

Here, with dogmatic brevity, are a few definitions:

Healthcare Terms	Meaning
Health maintenance examination, preventive health study, systematic review of health systems, interdependent multiphasic health evaluation	Physical Examination
Medical Center, Health Center, Health and Allied Sciences Center, Multiphasic Health Utilization and Implementation Center	Hospital
Ambulatory Food Services, Central Food Processing Center	Cafeteria
Ambulatory Crisis Center, Comprehensive Care Center, Health Crisis Center	Emergency Room
Ambulatory Care Services, Supportative Health Systems, Ancillary Outreach Programs	Outpatient Departments
President, Vice-President, and Corporate Officers for Preventive and Allied Health Maintenance	Hospital Administrators
Primary Resource Nurse	Floor Nurse
Utilization Coordinating Nurse	Head Nurse
Primary Health Care Physician, Total Health Care Physician	General Physician
Uniphasic Physician	Specialist
Health Care Management, Health Care Maintenance, Multiphasic Services and Planning	Diagnosis and Treatment
Multiphasic Analyses, Digitalized Supportative Studies	Laboratory Tests
Delivery of Health Care, Universal Health Care, Health Care Systems	Medicine

Conclusion

Use these gambits often. You'll find them ideal for obtunding sharp-witted opponents. Indeed, if you use these often enough, you may even induce complete cerebral shutdown.

Calendar of Events

December

4—Minneapolis Ophthalmology Society, 12:15 p.m., Central YMCA, Room 104.
5—Abbott Hospital Staff meeting.
5—Unity Hospital Staff Meeting.
6-9—American Rheumatism Association, Pittsburgh Hilton Hotel, Pittsburgh.
7—Minneapolis Surgical Society, Minneapolis Club.
7—Twin Cities Orthopaedic Society, 6:30 p.m., Town and Country Club, St. Paul.
8—Minnesota Academy of Ophthalmology and Otolaryngology.
9—Minnesota Academy of Family Physicians Board of Directors meeting.
11—Hennepin County Academy of Family Physicians Chapter meeting, Minneapolis Athletic Club, Cavalier Room.
12—Eitel Hospital Staff meeting.
12—St. Mary's Hospital Staff meeting, 6:30 p.m., at the hospital. Election.
13—Minnesota Academy of Medicine, Town and Country Club, St. Paul. Dinner meeting. Visitors by invitation.
14—Fairview Hospital Staff meeting, 6:30 p.m., Minneapolis Club.
14—Hennepin County Academy of Family Physicians Executive Committee meeting, 7:30 a.m., Sheraton Ritz Hotel.

19—Fairview-Southdale Hospital Staff meeting, Camelot Restaurant, Jct. 494 and Hwy. 100.
20—Mercy Hospital Staff meeting, 6:30 p.m.
21—Lutheran Deaconess Hospital Staff meeting.
22—Methodist Hospital Staff meeting, 8:00 a.m. Election by mailed ballot.
26—North Memorial Hospital Staff meeting, 6:15 p.m., at the Golden Valley Golf Club.

Alcoholism and Drugs

Addiction

T. G. LARSON, M.D.

ALCOHOL IS BY far the most commonly abused drug in America. However, alcoholics share basic characteristics with all addicts. Actually alcoholics and other drug addicts often change to another agent for various reasons. Most often, withdrawal effects of one agent are countered with the intoxicant effects of another agent. Pep pills are thus used to counter hangover and depression caused by withdrawal effects of sedatives and vice versa. Alcoholics frequently interchange other sedatives such as barbiturates and tranquilizers because they are available and are difficult to detect.

Addiction is the repeated use of a foreign agent to produce a previously experienced mental and physical state. Without this repeated use of the foreign agent the addict becomes anxious and depressed. He may become acutely disturbed emotionally. If the addict cannot obtain his drug at all, he may be in danger of acute withdrawal symptoms which may range from mild muscle cramps to convulsions and death. For the typical addict, his drug gradually becomes the dominant factor controlling his thought and behavior. His "life style" (work, friends, family, health) is determined by his compulsive addiction.

Gradually the addict develops certain characteristics which are generally shared by other addicts regardless of the agent which is used. He is seclusive, secretive and anti-authority in his relationship to other people. He denies that he is "hooked." He rationalizes that he can quit the agent if he really chooses to. He becomes irritable when anyone confronts him with his addicted state. Gradually or abruptly, he sacrifices all interests and responsibilities in order to continue his addiction. Unless his addiction is interrupted, the addict deteriorates mentally and physically to a point of where he suffers permanent damage or death.

The actual conditions and problems seen in addiction depend upon the stage of addiction. Four stages of addiction are described. In each stage the problems for the addict, his family and society are outlined. The actual problems for the individual addict may vary due to age, race and social class.

Dr. Larson is the Medical Director of Northern Pines Mental Health Center, Inc., Little Falls, Minnesota.

Stage 1

The episodic repeated use of the addictive agent. The addict continues to work but misses work due to hangovers now and then. He continues a superficial role in family and society. In this stage the core of addiction is established. The addict begins to use the agent in solitude and to excess without regard for his immediate circumstances. He begins to hide the times and extent to which he uses the agent. Most important, he denies the drug has him "hooked." This denial extends to his own comprehension of his condition.

Addict: Suffers from hangovers, fatigue and depression. Feels guilty about lapses in responsibility, often irritable and preoccupied.

Family: Income lost due to missed work and cost of agent. Marital discord caused by intoxicated states. Children lack carefree, spontaneous interaction with parent. Children see example of meeting problems by denial and resort to drug.

Society: No noticeable direct effect. Later inherits children of the family who may be psychologically deficient and emotionally vulnerable to repetition of parent's addiction.

Stage 2

Addict uses drug almost every day. He misses work, abdicates role in family, curtails social life. Addict at this stage is never free from the disease of addiction. He is constantly in a state of intoxication or in withdrawal misery. A constant acute brain impairment clouds his judgment and his understanding of his condition. He loses control of self regulating abilities and is dependent upon others for constructive decisions. He must be regarded as physically and mentally ill.

Addict: Must use more and more of agent to control withdrawal misery. Alienated from family and friends. Feels isolated and depressed much of the time when he is sober enough to know what his feelings are. Frequently fired from jobs, loses personal esteem. Begins to compro-

mise moral values and responsibility. Denial of problem is solidified.

Family: Continual financial problems. Wife must work if addict is husband. Spouse must build life separate from addict. Children often without parental support and guidance. Addict usually abusive emotionally and physically to family. Family unit borders on collapse.

Society: Loss of stable worker, loss of self-sustaining family unit. Must absorb and maintain children deficient in emotional, moral and responsible attitudes.

Stage 3

Addicts work only sporadically. He is separated from family. He associates with other addicts only. Frequently requires hospitalization and often is in trouble with the law. Gross moral deterioration is evident.

Addict: Mental confusion pervades activities and thought. Agonizing guilt feelings about failures. Feels trapped, physically ill most of the time. Frequently suicidally depressed. Feels totally isolated, making addictive agent his only solace.

Family: Divorced or separated with consequent personal problems to members. On AFDC if father is addict; children in foster homes if mother is addict. Family suffers from society's disfavor and prejudice. Children likely to be school dropouts. They are prone to repeat the parent's distorted relationships and their irresponsibilities.

Society: Must bear cost of supporting addict in hospital or jail plus the cost of family on welfare. Society suffers from insult of crimes by addict such as stealing, burglary, armed robbery, assaults, drunk driving, deaths, etc. Children of addict often untrained and unemployable. They need vocational training and frequently are too disturbed or too irresponsible to support themselves or their families.

Stage 4

Denial of problem is replaced by inability to comprehend the problem. Memory deficit, loss of problem solving ability, and lack of comprehension indicate brain dysfunction and probable permanent brain damage. Addict should be considered psychotic and not responsible for his decisions. If damage is permanent, the addict must be regarded as permanently inadequate to make major decisions for himself. Institutional care is usually mandatory unless and until brain damage is corrected.

Addict: Must endure enforced or voluntary hospitalization indefinitely to save his life. Inability to comprehend his condition further confuses the addict's need for protection from himself.

Family: Hopeless loss of parent and spouse is recognized. Children confused and embarrassed by prolonged hospitalization of parent. Helplessness permeates the family. They are powerless to change their condition. Frequently the family just quits trying. They suffer from loss of self-esteem, guilt feelings, and chronic depression.

Society: Cost of long term hospitalization of addict must be born by taxpayers. Almost impossible to rehabilitate addict due to personality and cerebral deficit. Must absorb children who are handicapped by severe emotional problems and lack of motivation to change.

The basic cause of addiction is unknown. As in most problems where the cause is unknown we find many unproven theories. Without proven facts, anyone's theory about causation is just as good as anyone elses. Actually we may find that there is no single cause.

Whatever the cause, there does seem to be a sequence of events leading to addiction. Addiction often starts in a social setting where the potential addict is introduced to the addicting agent. Into this setting the potential addict brings a subtle antisocial attitude. Specifically this antisocial attitude is a disregard of society's knowledge and attitude towards the dangers of drug abuse. This antisocial attitude sets up the mechanism of denial which is so basic to the addict's personality. It is this denial of a problem which allows him to continue the abuse of the drug.

No matter what the cause of addiction may be, once established the addict seems never to lose the potential to abuse drugs. In a real sense the addict's reflexes and responses may be compared with riding a bicycle. Once the complex reflexes and coordinating movements necessary to ride a bicycle are mastered, these actions become automatic and permanently established. With hardly any conscious effort the person who has not ridden a bicycle for many years can reactivate these pathways and ride a bicycle again. In much the same way once addictive pathways and reflexes are established they seem to be permanently fixed. The addict thus is constantly in danger of reactivating these pathways which constitute addiction.

Present day treatment of addiction is unsatisfactory. Conventional psychiatric treatment is essentially ineffective. Due to his denial of addiction the addict is unmotivated to stop his drug abuse.

The only known effective control of the problem of addiction is to separate the addict from the addictive agent. Drying up the sources of addictive drugs is not practical since most of the drugs abused have a legitimate use for many non-addicts.

Thus, there are only two known ways to control addiction:

1. External restraint of addict from his drug. This is accomplished by institutionalization such as in a hospital. This is costly and only temporarily effective since the addict is not motivated to give up his drug. Relapse into addiction shortly after discharge is the rule rather than the exception.
2. Internal restraint of the addict from his drug. Some addicts retain enough insight to realize that drug abuse is causing most of his current problems. For the addict, to deny himself the drug requires a major change in his life style. He must be motivated sufficiently to undergo a "Conversion" to a life style without drugs. Several group therapy organizations offer assistance to these addicts. Alcoholics Anonymous, Synanon, and the Jesus Movement rely on the mechanism of "conversion" to a lifestyle without drugs. To join these groups the addict must be "converted" to the beliefs and attitudes of the respective groups. The conversion experience gives the addict motivation and a strong reason to change his addictive lifestyle to one without drugs.

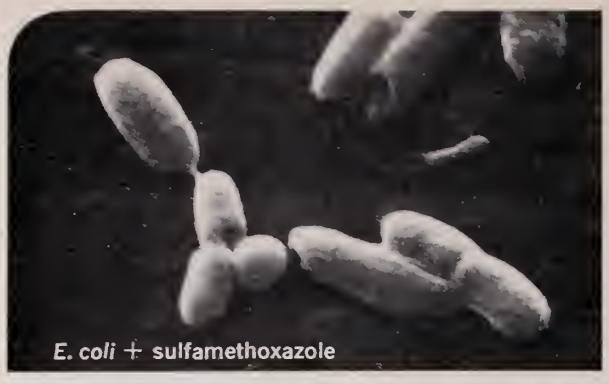
Unfortunately, only a small percent of addicts have enough insight and motivation to change. Most addicts deny their problem and thus are untreatable, except by physical separation of the addict from his drug. Usually this means enforced or voluntary institutional care in a hospital, jail and such.

Since treatment of addiction on the whole is unsatisfactory, prevention of the problem seems to be the only practical approach to addiction. Some major changes in society's attitude toward drug abuse must occur. Society should disapprove generally and individually the abuse of all psychoactive chemicals. The "cute" behavior of the drunk should not be viewed with tolerance and acceptance. Movies and television show many scenes where drinking alcohol or taking drugs is commonplace. Children observe the hero and heroine running to the ever present bottle or pill box when they are under pressure. This solution to problems really sets the stage for young people to do likewise when they are under pressure. These practices should be removed from the public media. A stark honest description of addiction and its problems to the addict, his family, and society should be emphasized.

The use of negative advertising has been established in the case of cigarette addiction. Television advertising is now prohibited and has been replaced to some extent by advertisements which discourage cigarette smoking. The law now requires a printed warning that "cigarette smoking is dangerous to health" on each pack of cigarettes.

A similar negative advertising should be demanded for the abuse of drugs and alcohol. Actually the risks to health from the abuse of drugs and alcohol is just as certain as is cigarette smoking.

The potential addict should be confronted with the damage he can do to his family, his friends, and his society as well as to himself. First exposure to drugs today is in the elementary grades. This fact indicates that drug information and drug addiction problems should definitely be presented to children at least by the fifth grade in rural as well as urban areas.



References 1-5 will be found on page 1170.

Encounter under the Scanning Electron Microscope

SEM reveals changes in *E. coli* exposed to antibacterial agents

The Scanning Electron Microscope (SEM) is the only instrument which gives 3-dimensional views on a microscopic level. This permits the surface morphology of microorganisms to be observed in detailed perspective. Changes in surface morphology of *E. coli* exposed to various antimicrobial agents are seen on the following page. An SEM photomicrograph of normal control *E. coli* appears above.

Different modes of antibacterial action — Similar changes in morphology

As part of a series of experiments,[1-3] strains of *E. coli* proven susceptible to each antibacterial agent were exposed to 1 MIC of the respective antibacterials for a three-hour period. Included were cell-wall-active drugs, ampicillin and cephalothin; a drug interfering with intracellular protein synthesis, tetracycline; and a chemical agent which acts by interference with para-aminobenzoic acid, sulfamethoxazole.

As seen above, elongation of the bacilli, mid-cell defects and spheroplast-like forms may be appreciated with the SEM technique. These changes in bacterial morphology were similar . . . regardless of the antibacterial agent used and irrespective of its mechanism of action.

"At present, the significance of these observations in clinical infection must be considered with caution, but it is hoped that these data will stimulate a reevaluation of present concepts of the nature and role of morphological variants of bacteria exposed to a variety of antibacterial factors."[2]

It should be noted that no clinical conclusions can be drawn from this study, as it is not always possible to extrapolate *in vitro* data to humans.

References: 1. Klainer, A. S.; Fass, R. J., and Perkins, R. L.: Scientific Exhibit presented at the 25th American Medical Association Clinical Convention, New Orleans, La., Nov. 28-Dec. 1, 1971. **2.** Klainer, A. S., and Perkins, R. L.: *Antimicrob. Agents Chemother., 1*:164, 1972. **3.** Klainer, A. S.: Data on file, Hoffmann-La Roche Inc., Nutley, N.J.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Acute, recurrent or chronic nonobstructed urinary tract infections (primarily pyelonephritis, pyelitis and cystitis) due to susceptible organisms. **Note: Carefully coordinate *in vitro* sulfonamide sensitivity tests with bacteriologic and clinical response; add aminobenzoic acid to follow-up culture media. The increasing frequency of resistant organisms limits the usefulness of antibacterials including sulfonamides, especially in chronic or recurrent urinary tract infections.** Measure sulfonamide blood levels as variations may occur; 20 mg/100 ml should be maximum total level.

Contraindications: Sulfonamide hypersensitivity; pregnancy at term and during nursing period; infants less than two months of age.

Warnings: Safety during pregnancy has not been established. Sulfonamides should not be used for group A [illegible] hemolytic streptococcal infections and will not eradicat[illegible] prevent sequelae (rheumatic fever, glomerulonephritis) of [illegible] infections. Deaths from hypersensitivity reactions, agranulo[illegible] sis, aplastic anemia and other blood dyscrasias have bee[illegible] ported and early clinical signs (sore throat, fever, pallor, pur[illegible] or jaundice) may indicate serious blood disorders. Frequent [illegible] and urinalysis with microscopic examination are recommen[illegible] during sulfonamide therapy. Insufficient data on children u[illegible] six with chronic renal disease.

Precautions: Use cautiously in patients with impaired [illegible] or hepatic function, severe allergy, bronchial asthma; in gluc[illegible] 6-phosphate dehydrogenase-deficient individuals in whom [illegible] related hemolysis may occur. Maintain adequate fluid intal[illegible] prevent crystalluria and stone formation.

Adverse Reactions: *Blood dyscrasias* (agranulocyt[illegible]

Encounter in Clinical Practice

Control of primary bacterial offenders

Antibacterial Gantanol® (sulfamethoxazole) controls susceptible strains of *E. coli* and other gram-negative and gram-positive organisms often implicated in acute nonobstructed pyelonephritis and cystitis.

Prompt antibacterial blood and urine levels

In from 2 to 3 hours after the initial 2-Gm adult dose, antibacterial levels are present in both the blood and urine.

B.I.D./T.I.D. dosage for around-the-clock coverage

Subsequent 1-Gm doses provide up to 12 hours of antibacterial coverage. More severe u.t.i. may require a q. 8 h. dosage regimen. Either schedule provides coverage during the waking and sleeping hours—especially important during hours of sleep when normal urinary retention tends to favor bacterial proliferation.

Also effective in nonobstructed chronic and recurrent u.t.i.

It is not uncommon for the elderly and the debilitated to develop chronic and/or recurrent nonobstructed urinary tract infections such as pyelonephritis and cystitis. Such cases often respond satisfactorily to Gantanol. The increasing frequency of resistant organisms is a limitation of usefulness of antibacterial agents including sulfonamides, especially in chronic or recurrent u.t.i.

Your Option: Tablets or Suspension

Either dosage form—the Tablets or the pleasant-tasting, cherry-flavored Suspension—can provide the dependable antibacterial activity necessary to control susceptible nonobstructed cystitis and pyelonephritis. Symptomatic improvement may usually be expected in 24 to 48 hours. The usual precautions with sulfonamide therapy should be observed, including adequate fluid intake. Gantanol (sulfamethoxazole) is generally well tolerated with relative freedom from complications; the most common side effects are nausea, vomiting and diarrhea. Frequent c.b.c.'s and urinalyses with microscopic examination are recommended.

In nonobstructed cystitis and pyelonephritis due to susceptible organisms

Gantanol®
(sulfamethoxazole)
Basic Therapy

---

astic anemia, thrombocytopenia, leukopenia, hemolytic ane-
, purpura, hypoprothrombinemia and methemoglobinemia);
rgic reactions (erythema multiforme, skin eruptions, epider-
necrolysis, urticaria, serum sickness, pruritus, exfoliative
matitis, anaphylactoid reactions, periorbital edema, conjunc-
l and scleral injection, photosensitization, arthralgia and
rgic myocarditis); *gastrointestinal reactions* (nausea, emesis,
ominal pains, hepatitis, diarrhea, anorexia, pancreatitis and
natitis); *CNS reactions* (headache, peripheral neuritis, men-
depression, convulsions, ataxia, hallucinations, tinnitus, ver-
and insomnia); *miscellaneous reactions* (drug fever, chills,
c nephrosis with oliguria and anuria, periarteritis nodosa and
phenomenon). Due to certain chemical similarities with
e goitrogens, diuretics (acetazolamide, thiazides) and oral
oglycemic agents, sulfonamides have caused rare instances
goiter production, diuresis and hypoglycemia as well as thyroid malignancies in rats following long-term administration. Cross-sensitivity with these agents may exist.

Dosage: Systemic sulfonamides are contraindicated in infants under 2 months of age (except adjunctively with pyrimethamine in congenital toxoplasmosis).

Usual adult dosage: 2 Gm (4 tabs or teasp.) initially, then 1 Gm *b.i.d.* or *t.i.d.* depending on severity of infection.

Usual child's dosage: 0.5 Gm (1 tab or teasp.)/20 lbs of body weight initially, then 0.25 Gm/20 lbs *b.i.d.* Maximum dose should not exceed 75 mg/kg/24 hrs.

Supplied: Tablets, 0.5 Gm sulfamethoxazole; Suspension, 0.5 Gm sulfamethoxazole/teaspoonful.

NORTH CENTRAL MEDICAL CONFERENCE

Your South Pacific Adventure awaits you.

We leave on February 22, 1973 from Minneapolis-St. Paul

Join us for two sun-filled weeks in the South Pacific lands of New Zealand, Australia and Tahiti.

The cost? Just $998 complete.

Our trip to the lands "Down Under" includes Pan Am jet flights, first class hotels, two meals a day plus a host of many extras to make your adventure unforgettable!

NEW ZEALAND—Auckland's lavish gardens . . . the volcanic geysers of Rotorua . . . Waitemata Harbor and the Tasman Sea . . . the friendly Maoris and their fascinating villages.

AUSTRALIA—Sophisticated Sydney . . . the magnificent new opera house . . . the harbor bridge . . . koala bears, kangaroos . . . rugged mountains and superb surfing beaches.

TAHITI—Exotic Papeete . . . lush tropical paradise . . . gentle, life-loving Tahitians . . . white sand beaches and crystal waters.

Space on our South Pacific Adventure is strictly limited. To confirm your reservation, return the coupon today.

SEND TO: North Central Medical Conference
375 Jackson Street
St. Paul, Minnesota 55101

Fracture Conference

Care of Fractured Hip in the Aged

ELI J. KRIGSTEN, M.D., PETER L. BOMAN, M.D. AND EINER W. JOHNSON, JR., M.D.

Eli J. Krigsten, M.D.:

As an orthopedic problem, fracture of the hip in an elderly person presents several facets not apparent in younger patients. These have been covered in several good articles.[1-7] The mortality and the morbidity rates have varied somewhat from series to series. Niemann and Mankin[1] recently noted that 36% of the patients died within six weeks after operation, with the peak incidence in the second week. Of the remaining patients in the group who were ambulatory before operation, only 20% ever walked again. Niemann and Mankin believed that age and wound infection were the major causes of death and that the type of fracture, operative technique, and duration of anesthesia were not significant in this respect.

In the series of Manpel and colleagues[4] the mortality rate was less if the fracture was more distal: 13.2% after subcapital fracture and only 4.1% after subtrochanteric fracture. Fitts and colleagues[7] stated: "The life expectancy of the patient who survived the first six months after operation was not appreciably less than the general population." They too found greater mortality and morbidity after intertrochanteric fracture than after neck fracture. Among the survivors, however, 97% of those with intertrochanteric fracture had a good result, avascular necrosis occurring in only 13%.

A major influence in the survival of Niemann and Mankin's[1] patients was major wound infection, which occurred in almost 20% and was especially common in patient with prostheses. Circumstances possibly causative were lack of foreskin cleanliness, poor bowel and bladder control, poor inherent hemostasis, and a nebulous condition they called "poor resistance." All the femoral-head prostheses in their series were inserted through a Fletcher-Marcy (posterior) incision which was not routinely drained and was easily soiled by excretions.[1]

Fracture Conference, April 28, 1969.
Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

We have dealt recently with hip fractures in some elderly patients at the Rochester State Hospital whose pyschiatric difficulties made special problems. To get them to walk as soon as physically possible was hard, since many could not understand simple instructions. Parkinson's disease was an added handicap in some cases. In the Oltman series,[5] made up of psychiatric patients in Connecticut, the peak incidence of fracture occurred in the eighth decade of life, the average age being four years less among men than among women. Some patients fell because of ataxia. In 1960, Sheldon of England described what he called a "drop" attack, intimating that about one fourth of all falls by the aged occurred for no apparent reason. Oltman and Friedman[5] believed hip fractures caused higher mortality and greater incidence of degenerative conditions (especially cardiovascular and renal) in psychiatric patients than in others. In the 74 autopsied cases, the most frequent cause of death was bronchial pneumonia.

These statistical studies suggest that hip fracture is a lethal condition. Most authorities agree that internal fixation within three days after the injury produces the best survival rates. In Bickel and Jackson's[2] series of intertrochanteric fractures, the average time elapsing before internal fixation was two days and the mortality rate was approximately 8%, which is lower than the rates in most other large series.

The fortunate results we have been able to obtain on our service are due primarily to our medical colleagues, who cooperated in preoperative evaluation and care. The selection and administration of anesthetics and the help of our respiratory service have also been important. In addition, we have been using anticoagulants prophylactically, beginning usually on the third postoperative day and continuing until the patient either is actively ambulating or is dismissed.

Peter L. Boman, M.D.:

Preoperative evaluation of an elderly patient is

just as important as proper selection of surgical approach or postoperative care. The patient's history should be carefully reviewed. One should ask especially about the cardiovascular, respiratory, and metabolic systems and about intercurrent diseases. It is important to make a careful physical examination, if this is possible. An evaluation of mental function will make it possible to assess any future changes. And finally, adequate laboratory examinations, including electrocardiography, are needed.

Such an extensive examination will usually answer the question: When is the patient best able to tolerate anesthesia and surgery? McLaughlin believed that the time of injury was best and that such injuries should be considered surgical emergencies. Contraindications are congestive heart failure, cardiac arrhythmia, and diabetic acidosis. Lipscomb,[6] however, believed that these are not surgical emergencies and recommended that operation be performed when the internist, anesthesiologist, and surgeon agree that the time is ripe.

Dr. Kimmel:

For orthopedic anesthesia, the aged are a most difficult group. One major improvement has been the change from the concept that hip surgery is an emergency. There is an optimal time: not immediately and not a week later, but perhaps within 24 hours or at least within three days.

The choice of anesthesia is not simple and usually has to be made with cooperation between the surgeon and the anesthesiologist. A difficult fracture may take three or four hours, thus exceeding the duration of spinal anesthesia. Also, under general anesthesia the patient with respiratory problems can be ventilated well; often his condition is better at the end of surgery than at the start. Although there are problems with spinal anesthesia, I prefer to use this method when I can. The major problem is getting the patient in position to receive it, because he frequently has a lot of pain. Another problem is that spinal anesthesia predisposes to hypotension, which is bad for these patients. They have limited coronary reserve, and hypotension often contributes to their early death.

Another method is local infiltration, which we have recently used in two extremely poor-risk patients with good results. So there is no easy answer, nor any one way to handle these patients. The choice depends largely on the patient's condition and on the surgeon's and anesthesiologist's combined judgment.

Dr. Krigsten:

We have operated on several elderly fracture patients under spinal anesthesia and on one under local anesthesia. He had pulmonary fibrosis and was not a candidate for general anesthesia. The local anesthesia worked well and the patient did well.

Dr. Cabanela:

I present the case of an 82-year-old woman who fractured her right hip in a fall at home. The past medical history included severe kyphoscoliosis with decreased chest expansion arteriosclerotic heart disease with mitral insufficiency, and a fracture of the left hip sustained 15 years previously. The fracture of the right hip was openly reduced and internally fixed. The roentgenogram made on admission is shown in Figure 1.

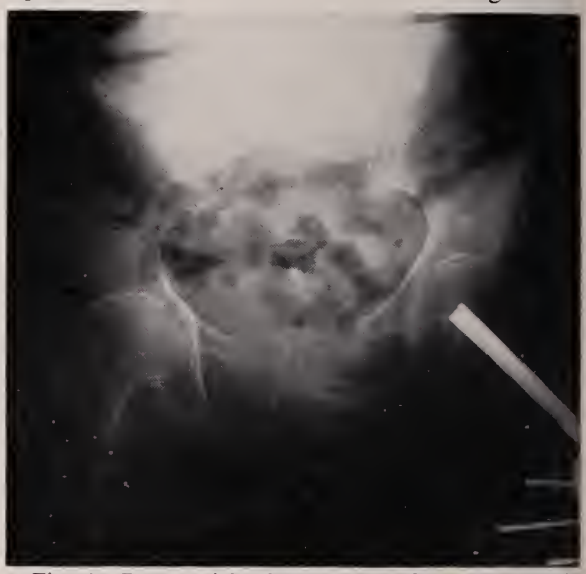

Fig. 1—Recent right femoral-neck fracture and old left femoral-neck fracture.

Dr. Krigsten:

Her left hip had healed nicely. Although the fracture does not show well, it is situated distally in the femoral neck. Her kyphoscoliosis was so severe that she was bent almost to a 90° angle. Her size and her spinal deformity presented a real problem in positioning her for operation and in doing it. The fixation we were able to obtain is shown in Figure 2. Some articles have described the backing out of the Smith-Peterson nail in this type of fracture. For insurance, therefore, I inserted a Knowles pin beside the V-blade plate. She was ambulating with a walker two weeks after operation.

Fig. 2—Same patient as in Figure 1. Recent, right femoral-neck fracture internally fixed with V-blade plate and one Knowles pin.

Dr. Cabanela:

The next patient is an 86-year-old man who woke up one morning recently with pain in the right hip aggravated by any motion of the lower extremity. He was brought to the emergency room, where the roentgenograms shown in Figure 3 were taken.

Dr. Krigsten:

This man came in a semicomatose condition. Figure 4 shows our fixation. We used four Knowles pins and, although we thought we had put them in a diamond pattern, they do not appear so on this roentgenogram. He did well postoperatively; and on dismissal he was lucid, talking, and ambulating with crutches. His post-

Fig. 4—Same patient as in Figure 3. Right femoral-neck fracture internally fixed with four Knowles pins, as seen at time of operation.

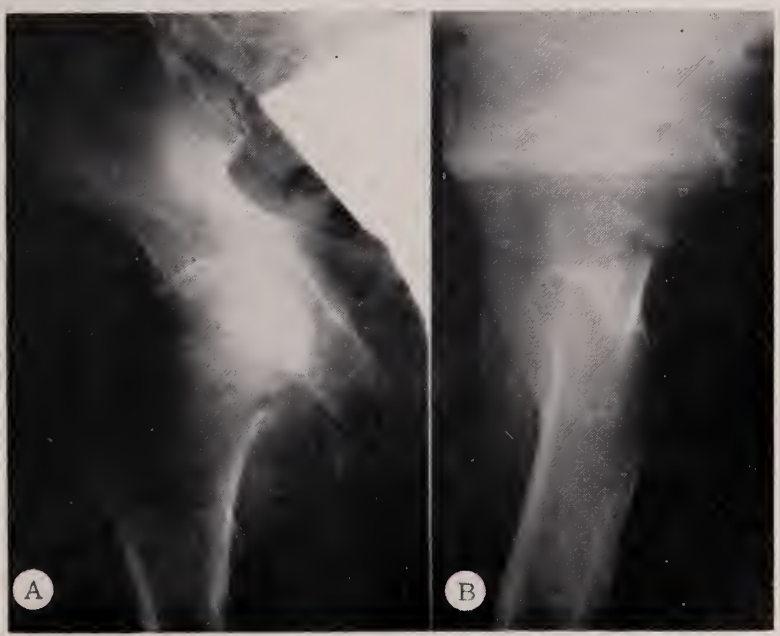

Fig. 3—Right femoral-neck fracture. *(A)* Anteroposterior view. *(B)* Lateral view.

operative care was certainly enhanced by the help we got from the respiratory service.

Dr. Cabanela:

A 69-year-old woman fell at a nursing home during a dizzy spell, sustaining an injury to the right wrist and the right hip and lacerations of the scalp. On arrival in the emergency room she was not alert. She had good peripheral pulses and a typical deformity of the fractured hip. The past history included severe long-standing Parkinson's disease, marked osteoporosis, two previous episodes of syncope, and fracture of the left hip treated here with a Matchett-Brown prosthesis in July 1968.

Dr. Krigsten:

This woman had two hip fractures within a year. At a fracture conference a couple of years ago we discussed whether we should attempt to nail fractures of the femoral neck in patients with Parkinson's disease. I think it is generally conceded that this is not the best course. Insertion of a primary prosthesis is best, if age will allow it. The wrist fracture hindered use of crutches, and progress was rather slow; but the patient was using a walker by the time she left the hospital.

One last comment is that often we take a somewhat aloof attitude because these patients are old and debilitated and nobody welcomes the many problems they present. But a little time spent in perhaps just patting their hands and combatting their depression may be worthwhile. It is gratifying to see an elderly person walk out of the hospital after sustaining a hip fracture, which can be a lethal injury.

Summary

Let me make these points: (1) Appropriate and complete preoperative evaluation of the elderly patient is essential to proper fracture care. (2) Operation on these patients should not be done as an emergency, but probably should not be delayed more than three days except in dire circumstances. (3) The type of anesthesia is important. The anesthesiologist will be of prime help in selecting the proper type and should be asked to see the patient preoperatively. (4) Internal fixation of the fracture is the best treatment, where possible, and allows early mobilization.

Dr. Spink to Write History of Infectious Diseases

Dr. Wesley Spink, Regents' Professor of Medicine and Comparative Medicine at the University of Minnesota, has been awarded a $77,000 project grant by the Department of Health, Education and Welfare. Dr. Spink, who will retire June 30, 1973, plans to trace the evolution in the scientific control of infectious diseases.

Results of Spink's three-year project, which will begin July 1, 1973, will be published in a comprehensive monograph presenting historical highlights in the control of infectious diseases, details of outstanding advances and discussion of progress and problems of the future in this field.

The volume is planned in five parts: the 19th century; the first two decades of the 20th, including a review of medical knowledge and control of infectious diseases at the end of World War I; the period from 1920 to 1937 (during which Spink began his career as a student of infectious diseases); 1937 to 1970, a period encompassing World War II, and marked by more advances in the specific therapy of disease than at any time in medical history; and a forecast of future developments in the control of infectious diseases.

The volume will be published by the University of Minnesota Press.

Book Reviews

FRONTIERS IN COMPARATIVE MEDICINE by W. I. B. Beveridge. Published by the University of Minnesota Press, 1972. 104 pages. Price $4.95

This volume is subtitled "The Wesley W. Spink Lectures on Comparative Medicine, Volume 1" suggesting that the University of Minnesota Press will publish subsequent volumes as this biennial lectureship continues.

The first series of lectures was a peripatetic affair with W. I. B. Beveridge, Professor of Animal Pathology at the University of Cambridge, England, speaking at Carleton College, University of Minnesota-St. Paul and University of Minnesota-Duluth. The three lectures comprise the three chapters of this book. The first is "Logic of the Comparative Method" in which Beveridge explores the application of comparative medicine to human medicine. The second chapter, "Animal Model of Human Diseases" is concerned with the development of the great scientific programs of animal investigation in medical schools. And the third chapter "Comparative Study of Influenza" is a fascinating account of this most important epidemic disease as it has scourged the world in epidemics in recent centuries.

The choice of Beveridge to lead off this series of Spink lectures is a happy one. He presents this material so important in infectious disease in a way that expands the physician's horizon of interest far beyond the care of human patients.

This volume is a model of perfection in translating a series of lectures into book form. We look forward to further contributions in the Spink Lectureship Series.

Reuben Berman, M.D.
Editor

GENERAL UROLOGY by Donald R. Smith, M.D. Lange Medical Publications. Price: $8.50.

For a long time General Urology has been a fine urological textbook for medical students and a valuable reference for internes and general practitioners. Dr. Smith wrote the entire book himself except for five of the 31 chapters. The author has revised and updated all of the chapters in this new seventh edition. Never before has so much information been packed into such a compact volume with so little repetition. After each subject is discussed, the author lists a few of the important references. The book is well illustrated, and the text is printed on a double-column page for easier reading.

General Urology is a compendium of urological disorders, especially as they relate to the different genitourinary organs. Throughout the book the author stresses anatomy, embryology, pathophysiology, diagnostic techniques and differential diagnosis of genitourinary disorders. Although therapy is not discussed in detail, the initial and basic treatment of each disorder is presented in an excellent manner.

A number of diagnostic pearls are offered. For example, in Chapter 4, Dr. Smith describes an extremely valuable technique to aid in the diagnosis of abdominal masses in infants; namely, transillumination of the mass using a fiber optic light cord. The author also inserted chapters which are traditionally not included in most urological textbooks. Chapter 5 on Urologic Laboratory Examination, Chapter 9 on Instrumental Examination of the Urinary Tract, and Chapter 27 (Skin Diseases of the External Genitalia) are important additions.

Because General Urology is a compendium, it is understandable that certain subjects could not be discussed in greater detail. However, I would suggest expanding the section on treatment of uremia in Chapter 10, using higher doses of steroids than those recommended by the author for treatment of shock accompanying gram-negative bacteremia (Chapter 12), and adding a section on genitourinary blastomycosis in Chapter 13 (Specific Infections of the Urinary Tract).

I originally believed that General Urology was written specifically for medical students, internes, and practitioners other than urological surgeons. After reviewing this book, I would also recommend it for urological residents. It is a required textbook for Urological Assistant Trainees at our hospital, the Veterans Hospital.

Clyde E. Blackard, M.D.
Minneapolis, Minnesota

REVIEW OF MEDICAL PHARMACOLOGY by F. H. Meyers, E. Jawetz and A. Goldfien. Lange Medical Publications.

Intended as a comprehensive review of biochemistry for the medical student and practicing physician, Drs. Meyers, Jawetz and Goldfien have prepared a text entitled, "Review of Medical Pharmacology." Its paper back printing permits a price that will appeal to everyone. The chapter headings are handled in the traditional text book fashion.

Although authors have written individual chapters in the text, there is clearly a uniform style. The Table of Contents demonstrates the comprehensiveness of the book. The style is readable, the diagrams and tables are printed well and clearly. This book can be recommended as a shelf reference for all concerned with the subject of molecular biology.

Obviously, however, the moment a book of this nature is printed, the text must yield to the cutting edge of advances in the field.

Robert Maslansky, M.D.
Minneapolis, Minnesota

In gram-negative sepsis..

*Due to susceptible organisms

Schering

The antibiotic of first resort...

In suspected or documented gram-negative sepsis, GARAMYCIN Injectable may be considered as initial therapy.

- Effectiveness against the nosocomial problem pathogens of the 1970's
- Proven clinical effectiveness
- Risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended
- Effective against pathogens resistant to many commonly used antibiotics
- Versatility and convenience of administration

Garamycin®

brand of gentamicin sulfate injection

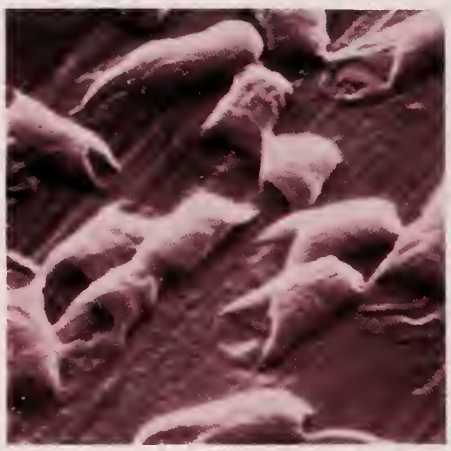
injectable

I.M./I.V.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

See Clinical Considerations section which follows...

The antibiotic to start with...



*In suspected or documented gram-negative sepsis due to susceptible organisms, GARAMYCIN Injectable may be considered as initial therapy. T decision to continue therapy with this drug should be based on the results o susceptibility tests, the severity of the infection, and the important concept contained in the Warning Box below.

An indispensable spectrum for today[1-3]

GARAMYCIN Injectable offers a high probability of effectiveness against virtually all of the gram-negative pathogens which are a growing cause of clinical concern. GARAMYCIN Injectable has also demonstrated striking activity against *Proteus* species, both indole-positive and indole-negative.[2]

Proven clinical efficacy[1,4-13]

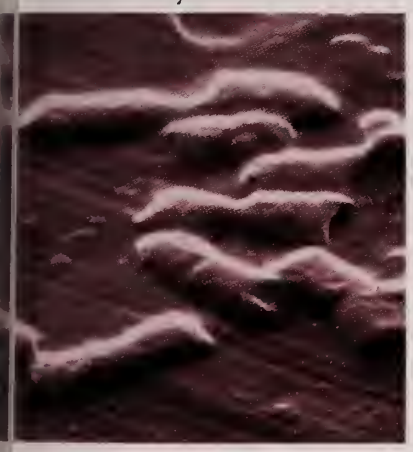
GARAMYCIN Injectable may be lifesaving in septicemia... may give a dramatic response in wounds and burns complicated by sepsis. GARAMYCIN Injectable has also demonstrated outstanding results in serious gram-negative infections other than sepsis, such as serious respiratory infections and selected urinary tract infections. To date, GARAMYCIN Injectable has been the subject of more than 1,500 published papers and 12 international symposia.

Note: The photomicrographs of gram-negative organisms reproduced here were obtained by a relatively new process employing a scanning beam electron microscope. The pathogens represented are *Klebsiella pneumoniae, Escherichia coli,* and *Proteus mirabilis.* The colors shown here are an artist's representation. The magnification is 10,000X.

WARNING: Patients treated with GARAMYCIN Injectable should be u close clinical observation because potential toxicity associated with use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, pr those with pre-existing renal dam treated with GARAMYCIN Injectabl usually for longer periods or with doses than recommended.

GARAMYCIN Injectable is potent



Schering

The antibiotic to stay with*

A high degree of sensitivity maintained[14-16]

Bacterial resistance to GARAMYCIN Injectable has not been a problem to date. In the laboratory, resistance has been demonstrated to develop slowly in stepwise fashion. No one-step mutations to high resistance have been reported. One investigator noted: "In the experience so far with [gentamicin], which is 7 or 8 years, in centers where it's been restricted to parenteral use, resistance has not appreciably changed."[14] Another authority "...found very little emergence of resistance" during eight years of use.[15]

In a survey of published studies on resistance to gentamicin, Weinstein and co-workers[16] report little change in bacterial sensitivity since 1963 in the percentage of sensitive strains. *In vitro* sensitivity was determined in all cases by the tube-dilution method.

Relatively low incidence of adverse reactions[3,14,17]

As with certain other aminoglycoside antibiotics, ototoxicity (primarily vestibular with gentamicin) and potential nephrotoxicity are risks of therapy.

Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy.

In contrast to kanamycin, neomycin, and streptomycin, which primarily cause deafness or difficulties in the auditory end organs of the eighth nerve, gentamicin primarily causes labyrinthian dysfunction.[14] This dysfunction, manifested by dizziness (not deafness) has, in most cases, been transitory.

As to nephrotoxicity, according to Finland,[3] "as in the case of kanamycin, the nephrotoxicity was found to be largely 'potential,' and very little if any has been encountered except with obviously excessive doses or in patients with already damaged kidneys."

Garamycin®
brand of gentamicin sulfate injection

injectable
I.M./I.V.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

hrotoxic, and this should be kept in d when it is used in patients with existing renal impairment.

fonitoring of renal and eighth nerve ction is recommended during therapy atients with known impairment of al function. This testing is also mmended in patients with normal al function at onset of therapy who elop evidence of nitrogen retention reasing BUN, NPN, creatinine or uria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

Usage in Pregnancy: Safety for use in pregnancy has not been established.

See Clinical Considerations section which follows...

When preculture signs point to gram-negative sepsis...

Garamycin® Injectable
brand of gentamicin sulfate U.S.P., injection 40 mg./cc.
Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin
For Parenteral Administration

WARNING: Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause toxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

INDICATIONS GARAMYCIN Injectable is indicated, with due regard for relative toxicity of antibiotics, in the treatment of serious infections caused by susceptible strains of the following microorganisms:

Pseudomonas aeruginosa, Proteus species (indole-positive and indole-negative), **Escherichia coli** and **Klebsiella-Enterobacter-Serratia** species.

Clinical studies have shown GARAMYCIN Injectable to be effective in septicemia and serious infections of the central nervous system (meningitis), urinary tract, respiratory tract, gastrointestinal tract, skin and soft tissue (including burns).

Bacteriologic tests to determine the causative organisms and their susceptibility to gentamicin should be performed.

Bacterial resistance to gentamicin develops slowly in stepwise fashion; there have been no one-step mutations to high resistance.

In suspected or documented gram-negative sepsis, GARAMYCIN may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important additional concepts contained in the "Warning Box." In the neonate with suspected sepsis or staphylococcal pneumonia, a penicillin type drug is usually indicated as concomitant antimicrobial therapy.

GARAMYCIN Injectable has been shown to be effective in serious staphylococcal infections. It may be considered in those infections when penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

CONTRAINDICATIONS A history of hypersensitivity to gentamicin is a contraindication to its use.

WARNINGS (See "Warning Box.")

PRECAUTIONS Neuromuscular blockade and respiratory paralysis have been reported in the cat receiving high doses (40 mg./kg.) of gentamicin. The possibility of these phenomena occurring in man should be considered if gentamicin is administered to patients receiving neuromuscular blocking agents such as succinylcholine and tubocurarine.

Treatment with gentamicin may result in overgrowth of nonsusceptible organisms. If this occurs, appropriate therapy is indicated.

ADVERSE REACTIONS

Nephrotoxicity: Adverse renal effects, as demonstrated by rising BUN, NPN, serum creatinine and oliguria, have been reported. They occur more frequently in patients with a history of renal impairment treated with larger than recommended dosage.

Neurotoxicity: Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss.

Numbness, skin tingling, muscle twitching, and convulsions have also been reported.

Note: The risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

Other reported adverse reactions, possibly related to gentamicin, include increased serum transaminase (SGOT, SGPT), increased serum bilirubin, transient hepatomegaly, decreased serum calcium; splenomegaly, anemia, increased and decreased reticulocyte counts, granulocytopenia, th[rombo]cytopenia, purpura; fever, rash, itching, urticaria, generalized b[ron]joint pain, laryngeal edema; nausea, vomiting, headache, increased [sa]tion, lethargy and decreased appetite, weight loss, pulmonary fi[bro]hypotension and hypertension.

DOSAGE AND ADMINISTRATION GARAMYCIN Injectable may be given [intra]muscularly or intravenously.

For Intramuscular Administration:

PATIENTS WITH NORMAL RENAL FUNCTION*

Adults: The recommended dosage for GARAMYCIN Injectable for pa[tients] with serious infections and normal renal function is 3 mg./kg./day, a[dmin]istered in three equal doses every 8 hours.

For patients weighing over 60 kg. (132 lb.), the usual dosage is 8 [mg.] (2 cc.) three times daily. For patients weighing 60 kg. (132 lb.) or les[s] usual dose is 60 mg. (1.5 cc.) three times daily.

In patients with life-threatening infections, dosages up to 5 mg./kg [day] may be administered in three or four equal doses. This dosage shou[ld be] reduced to 3 mg./kg./day as soon as clinically indicated.

*In children and infants, the newborn, and patients with impaired [renal] function, dosage must be adjusted in accordance with instruction[s set] forth in the Package Insert.

For Intravenous Administration:

The intravenous administration of GARAMYCIN Injectable is re[com]mended in those circumstances when the intramuscular route is not [feasi]ble (e.g., patients in shock, with hematologic disorders, with severe b[urns], or with reduced muscle mass).

For intravenous administration, in adults, a single dose of GARAM[YCIN] Injectable may be diluted in 100 or 200 cc. of sterile normal saline [or] a sterile solution of dextrose 5% in water; in infants and children [the] volume of diluent should be less. The concentration of gentamicin in [solu]tion, in both instances should normally not exceed 1 mg./cc. (0.1%) [and the] solution is infused over a period of 1 to 2 hours.

The recommended dose for intravenous administration is identic[al to] that recommended for intramuscular use.

GARAMYCIN Injectable should not be physically pre-mixed with [other] drugs, but should be administered separately in accordance with the [rec]ommended route of administration and dosage schedule.

HOW SUPPLIED GARAMYCIN Injectable, 40 mg. per cc., 2 cc. mult[iple]-dose vials for parenteral administration.

Also available, GARAMYCIN Pediatric Injectable, 10 mg. per cc., [2] cc. multiple-dose vials for parenteral administration. APRIL, '[72]

Review

Drugs in the Treatment of Cancer

A Review

ROBERT A. GREEN, M.D.

Many patients with disseminated cancer can be treated effectively with drugs: for cure in some cases, for prolonged survival in others, and for significant palliation in many. The concept is no longer new; some of these drugs, such as nitrogen mustard, have been in use for a long time while others continue to be developed. In the past few years theoretical considerations have led to new approaches in terms of combination therapy, some of which have been outstandingly successful such as in acute leukemia, Hodgkin's disease, and other lymphomas. It is being tried in several solid tumors as well. Steroid hormone treatment for cancers of the breast, prostate, and endometrium continues to be very important.

Anticancer Drugs

Anticancer drugs are generally divided into two main groups: chemotherapeutic agents and hormonal agents. This discussion is devoted principally to the chemicals of which there are now about 20 in general use. These are divided according to their chemistry and mode of action into four main groups: the alkylating agents, the antimetabolites, the antitumor antibiotics, and the vinca alkaloids. These chemicals act on tumor cells in different ways. The alkylating agents attack DNA directly, whereas the antimetabolites interfere in pathways of DNA synthesis. The antitumor antibiotics may have aspects of both of these actions. The vinca alkaloids are known to interfere with the mitotic process by effects on the mitotic spindle but probably also have another mode of antitumor action.

The majority of the anticancer chemicals have been in use for many years. The oldest, nitrogen mustard, first underwent clinical trials in 1942 although it was not reported in the literature until after World War II. Other alkylating agents, thiotepa, busulfan (Myleran), chlorambucil (Leukeran), cyclophosphamide (Cytoxan), and melphalan (Alkeran), were developed from the mid-1950's to the mid-1960's.

Methotrexate was among the first of the antimetabolites in use (1948) and was followed by 6-mercaptopurine (Purinethol), 5-fluorouracil, hydroxyurea (Hydrea), and cytosine arabinoside (Cytosar).

The first of the antibiotics with antitumor activity used extensively was actinomycin-D (Cosmegen) beginning in 1952-53. This was followed by Mithramycin and now by three other important antibiotics still available for investigative use only but probably to be released soon. These include: Daunomycin used in acute leukemia, Adriamycin undergoing trials in sarcomas and some other tumors, and Bleomycin, developed by the Japanese, effective in certain squamous cell cancers.

The vinca alkaloids, represented by Velban and vincristine (Oncovin) were first reported in 1962-63.

In addition to these major groups, there are other drugs which do not fit conveniently into the above classifications. They include L-Asparaginase, an enzyme prepared from e. coli which is useful in the treatment of lymphoblastic leukemia, procarbazine (Matulane), a drug useful in Hodgkin's disease, and the nitrosoureas, 1, 3-Bis (2-Chloroethyl)-1-Nitrosourea (BCNU) and 1-(2-Chloroethyl) - 3 - Cyclohexyl - 1 - Nitrosourea (CCNU), which probably act like alkylating agents, penetrate the blood brain barrier in contrast to the other known antitumor agents, and have been somewhat useful in glioblastomas. They also have been used in treatment of melanoma and lymphomas.

Although most of these drugs have been in use for years, many physicians have had little experience with them. This may be because of questions of their effectiveness, concern about their toxicity, or lack of information about how to use them—which drug for which tumor, dosage schedules, etc.

Dr. Green is associated with the St. Louis Medical Center, St. Louis Park, Minnesota.

Effectiveness is, of course, a valid concern, because admittedly few tumors are cured, but even in those cases where the known chances for response are small, most patients willingly take that chance. If it does nothing else, it gives them something for which to hope and perhaps a new lease on life, even though short-term.

With regard to toxicity, good responses are frequent enough to justify the risk, but the physician must make every effort to avoid intolerable toxicity and to warn patients about the possibility and nature of side-effects before treatment is started. Inadequate dosage which never produces toxicity may also never produce any clinical benefit. The therapeutic skill is in knowing how to push dosage to obtain maximum benefit and at the same time avoid intolerable toxicity.

Toxicity may be influenced by many factors, among them being the patient's general condition, age, and the amount of previous treatment. Elderly patients generally tolerate less drug, and patients in poor nutritional status with low plasma proteins, impaired liver function, etc., may be very poor risks. Patients who have had intensive prior radiation or chemotherapy also need to be treated very carefully in chemotherapy programs.

It is essential that patients on any of these agents be seen frequently, evaluated for possible toxic symptoms, and have their blood counts checked. This may be weekly or more often in intensive treatment programs; but, later, when dosage schedules have been established, it may be at two to three week intervals but rarely longer.

Specific Drug Toxicities

Cytoxan

The most common serious manifestation of Cytoxan toxicity is bone marrow depression, primarily leukopenia, and, although more platelet-sparing than other alkylating agents, the platelets also may be depressed by Cytoxan. Patients must be warned about the probability of hair loss which occasionally is severe. Actually this may occur with virtually any of the anticancer chemicals but is almost certain when Cytoxan and vincristine are given together. A not very common, but troublesome, side-effect of Cytoxan is hemorrhagic cystitis. To minimize this, it is important that patients on Cytoxan maintain a good fluid intake and output, and it is advisable to give dosage early in the day rather than at night when the offending excretion products may remain in the bladder overnight. Given intravenously, Cytoxan may cause nausea and vomiting.

5-fluorouracil

5-FU also causes bone marrow depression and it is important, as it is with all the chemotherapeutic agents, to check blood counts and platelet counts at regular intervals. Two common toxic reactions to watch for with 5-FU are diarrhea and cheilitis-stomatitis with small ulcerations most often at the mucocutaneous border of the lips. An occasional patient just does not tolerate 5-FU well and feels generally ill for two to three days after each dose. This may be unpleasant enough so that the drug has to be discontinued. An unusual, but quite rare, side-effect of 5-FU is a form of cerebellar ataxia which is reversible after cessation of the drug.

Vincristine

Vincristine causes little bone marrow depression in conventional doses; its main toxic effect is neurological. The earliest symptoms are paresthesias followed by loss of deep tendon reflexes, then by muscular weakness which may progress to paraplegia or quadriplegia. Severe constipation and even complete ileus may occur, and constipation should be avoided by a bowel program including softeners and laxatives. Cranial nerve involvement is unusual but may occur. Once neurological symptoms develop, dosage must be managed very carefully and treatment interrupted when weakness of the extremities is significant. Ordinarily time-dose related, these effects may occur quite early in the course of treatment with vincristine and must be looked for at regular visits. It is important to remind patients on vincristine of the possibility of hair loss.

The other alkylating agents (nitrogen mustard, melphalan, thiotepa, chlorambucil) have side-effects varying in degree but similar to those of Cytoxan. The other antimetabolites all depress bone marrow, like 5-FU. Velban, in contrast to vincristine, ordinarily does not produce as much peripheral neuropathy but may produce mental depression, headache, and constipation.

Any of these agents may cause marrow depression with leukopenia and thrombopenia (with the exception of bleomycin), and some of the less frequently used drugs have other side effects which will not be detailed here.

Results

The most spectacular results of chemotherapy

n cancer have been in the treatment of chorio-arcinoma, Burkitt's lymphoma, acute leukemia articularly in childhood), and certain tumors of hildhood including Wilm's tumor and neuroblas-oma. These are all relatively rare in any individ-ial practice and should be managed by physicians vith experience in their treatment since the possi-ilities for cure or for long term survival are the lirect results of intensive, knowledgeable, and vell-planned treatment.

In adults, far more common problems in the hemotherapy of disseminated malignant disease elate to cancers of the colon, breast, ovary, uterus, rostate, and the lymphomas. There is also a lace for chemotherapy, even though successful esponses are infrequent, in widespread cancer of he lung, kidney, testis, upper gastrointestinal ract and biliary system, in malignant melanoma, nd some brain tumors.

Lung Cancer

Lung cancer is the most common cause of can-er deaths in adults. When disseminated, chemo-herapeutic possibilities are limited to an objective esponse rate of perhaps five percent. Small cell ancers are somewhat more likely to respond than squamous cell cancers. When chemotherapy is used, occasional responses occur to large dose courses of Cytoxan in the small cell group. Nitro-gen mustard is somewhat more effective than Cytoxan for squamous cell cancers and can be given in conventional doses. These tumors occa-sionally will respond to a combination of actino-mycin-D and vincristine, but responses are usually of relatively short duration. Unfortunately, lung cancer commonly metastasizes to the brain where it cannot be controlled by chemotherapy, although cerebral metastases may be benefitted by radiation.

Colon Cancer

This next most common cause of cancer deaths has been treated with 5-FU with reasonable suc-cess for many years. The objective response rate is still in the range of 15-20 percent at best. There have been changes in the schedules of treatment resulting in less toxicity and greater ease of ad-ministration. Following the early intensive courses of 5-FU which often caused considerable toxicity, comparable results were produced with weekly intravenous 5-FU. Within the past two years it has been shown further that 5-FU is well tolerated and equally effective when given by mouth at weekly intervals provided, of course, that adequate doses are given. Too often 500 mg. of 5-FU are given routinely whereas larger doses should be given starting at 12 mg./kg. and raised to 15 mg./kg. per week or even slightly higher if toxicity does not occur. This can be continued indefinitely as long as the patient responds.

In the occasional patient who has poor tolerance to orally administered 5-FU, weekly intravenous administration should be resumed.

Patients with massive hepatic metastases as their major problem may be treated best by hepatic artery cannulation and infusion with 5-FU. This form of treatment also may be effective in primary hepatoma and in patients with hepatic metastases from other upper gastrointestinal cancers including metastases from pancreatic, gallbladder, and bile duct cancers.

The upper digestive tract cancers in general do less well than colon cancer, although occasional patients with stomach cancer respond to 5-FU. Cancer of the pancreas, gallbladder, and bile ducts occasionally respond to 5-FU alone but may re-spond better to intensive combined therapy using Cytoxan, 5-FU, Methotrexate and vincristine in combination.

Breast Cancer

The commonest cancer problem in females is breast cancer. When this becomes disseminated, hormonal maneuvers, basically castration premen-opausally and estrogen therapy postmenopausally, should be tried first. If these fail, and if chemo-therapy is to be given, the commonest of the chem-ical agents now used are Cytoxan and 5-FU. As many as 25 to 50 percent of such patient may have objective responses to these drugs. Cytoxan dosage varies from 50 to 200 mg. orally daily, and 5-FU should be started at 12 mg./kg. per week orally or intravenously and increased up to 15 mg./kg. to the point of mild toxicity.

In patients with very aggressive disease or when single drugs have failed, combination therapy may be tried using 5-FU, Cytoxan, Methotrexate and vincristine together. A significant number of such patients may respond even when they have failed to respond to single agents.

Ovarian Cancer

It seems established that the best results in the treatment of patients with invasive ovarian cancer are in patients whose disease can be treated with a combination of radiotherapy and chemotherapy, usually in that sequence. In those whose disease is thought to be too far advanced for radiation, chemotherapy alone using alkylating agents still

offers a good chance for palliation and prolonged survival. Thiotepa has been used extensively in the past, but Cytoxan is probably more commonly used at the present time and may be the first choice of drugs. Melphalan is effective also. The latter two may be given in intensive, short term, intermittent courses or by ongoing oral administration.

Other Cancers

In other commonly occurring cancers, such as prostatic and endometrial, hormonal agents, estrogens in the former, progestogens in the latter, continue to be the most effective. Chemical agents have relatively little effect.

In the more rarely encountered malignancies in adults, there are some good responses, particularly in testicular cancer for which Mithramycin in embryonal cell carcinoma has been quite effective. In some of the other cell types of testicular cancer, triple therapy, using as Actinomycin-D, chlorambucil, and Methotrexate is effective. Radiation after surgery remains the proper treatment of seminoma.

Hodgkin's Disease

Probably the most spectacular advance in the chemotherapy of malignancy has been in the treatment of advanced Hodgkin's disease with a combination of four drugs. This treatment is known as the MOPP program. The letters refer to nitrogen *m*ustard, *O*ncovin (vincristine), *p*rocarbazine (Matulane), and *p*rednisone. The number of responses and of complete remissions obtained is significantly greater, and the median survival of patients with stage IIIb and IV Hodgkin's disease doubled or trebled compared to results using single drugs.

There is less dramatic improvement, but nonetheless significant increased benefit from multiple drug treatment programs in patients with non-Hodgkin's lymphomas (lymphosarcoma and reticulum cell sarcoma). The MOPP schedule has been used in these diseases, or schedules in which Cytoxan is substituted for nitrogen mustard, or in which three drugs, Cytoxan, vincristine (Oncovin), and prednisone have been used in various schedules (COP).

Multiple Myeloma

The alkylating agents, melphalan and Cytoxan continue to be the drugs of choice in treating multiple myeloma. Different schedules are recommended by different investigators, with high dose, intermittent melphalan, usually given with prednisone, being recommended by some, and low dose daily maintenance melphalan by others. The long term results appear to be about the same with both.

Leukemia

The leukemias are where it all began in the modern era of chemotherapy of malignant disease. The possibilities for remission, long-term survival and even for some cures in acute leukemia, particularly in children, make it mandatory that these patients be treated only by those with wide experience in this field. The treatment of chronic leukemia with alkylating agents has changed less dramatically in the past few years. The use of hydroxyurea in chronic myelogenous leukemia represents an addition to management of that form of disease although myleran probably is still the drug of choice.

Summary

This represents an overview of the current status of the chemotherapy of malignant disease, an important modality of treatment for many cancer patients. No doubt the future will see the development of new, more sophisticated drugs. Further investigation of cellular kinetics will lead to new approaches in combination chemotherapy applying the known facts of drug action to the cyclic activity of cancer cells. Although no real successes have been reported to date, different types of adjunctive chemotherapy following surgery need to be investigated in carefully controlled studies of patients with breast and colon cancer. Finally, the use of reductive surgery, followed by chemotherapy, may lead to greater successes in the application of the new field of immunotherapy in cancer.

The value of presently available drugs and treatment schedules has been well established and offers hope to many cancer patients. They are readily available to clinicians whose practices include such patients.

Special Article

Vietnam Psychiatry

Portrait of Anarchy

LCDR HOWARD W. FISHER, MC, USNR

THE MILITARY PSYCHIATRIST is frequently called in lieu of disciplinary action and asked to medevacuate as "sick" or recommend administrative separation as "unsuitable" many of those who do not function well in Vietnam. The latter is a General Discharge Under Honorable Conditions, with full award of benefits, instituted at the "Convenience of the Government."

Much of the literature deals with explaining the low frequency of psychiatric "casualties" in Vietnam,[1-3] or aspects of drug abuse among troops.[4-7] Little attention has been paid to documenting irresponsible behavior in the persons who come to psychiatric attention in a combat zone.

This paper will explore the nature of the personalities referred to a psychiatrist in Vietnam and question the logic of psychiatric intervention. It will clarify that the psychiatrist is used as an "accomplice" in the character disorder's rebellion against authority, in an attempt to suspend appropriate disciplinary action.

Method

One thousand consecutive soldiers presenting to the Psychiatric Service, First Medical Batallion, First Marine Division, Danang, Vietnam were seen by this examiner, who served as Division Psychiatrist between March, 1970 and February, 1971. Histories obtained by personal interview and questionnaire were supplemented by Service Record Books and Health Records in an attempt to accumulate data on disciplinary action, prior arrests, and illegal drug use. A clinical diagnosis was made in each case, corresponding to military nomenclature.

Results

Referrals were officially through military physicians but the real source was frequently a commanding officer, officer in charge, lawyer, sergeant or chaplain. Eight men were referred by the Brig (Military Prison) for "Clemency Evaluation." Fifteen referrals were initiated by Congressional Investigations. Two referrals were ordered by the Commandant of the Marine Corps.

Rarely had the referring physician taken a social history or made a personality diagnosis. These same physicians returned men for reevaluation with implicit demand for medevac or recommendation for administrative separation for "psy-

chiatric reasons."

Table 1 documents Branch of Service, Enlistment, Tour, previous Psychiatric History, Age, Race, Marital Status, Rank, and Time on Active Duty for this sample.

There were no serious suicide attempts. Twenty nine men had a past history of suicide gestures. Forty two men had verbally threatened suicide in the past.

A notable paradox was the frequency with which the military pleaded inability to deal with violent or threatening men, especially if they were presentable, intelligent or said they "could not control themselves."

Thirty one men were diagnosed Psychotic Reaction, usually associated with suspected or confirmed drug abuse. All of these were medevacuated. Many were returned to duty by the outside hospital. Nine men were diagnosed Neurotic Reaction. Nine hundred sixty men were diagnosed Personality Disorder, usually Antisocial Type, and returned to duty for disciplinary action. All of these men were seeking non-punitive escape from the military, seeking medical justification. Many hoped to gain compensation as well. Only 134 men admitted their motivation openly.

Table 2 documents frequency of disciplinary action. Approximately 590 men were presumed to be involved with illegal drugs. There was evidence that offenses and drug abuse progressed under the influence of lack of limit-setting by authority, which was taken as tacit approval. There were progressively fewer inhibitions about admitting heroin use. Sixteen men admitted regular use of heroin. Thirty five men admitted use of LSD. Alcoholism was an overwhelming problem in 130 men, but many more abused it.

Twenty two men were seen in association with the charge of murder. One man actually murdered another after his threat had been ignored. "Fraggings" (fragmentation grenade detonations) of authorities seemed to occur in commands in timidated by threats or who were ambivalently permissive and tacitly encouraging hostile behavio in their troops.

Arrest histories prior to service appear in Tabl 3. Only those guilty of assault had been jailed Sixty eight men enlisted to evade prison. Five men admitted involvement in infanticide. One hundred fourteen men admitted responsibility fo out-of-wed-lock children.

Table 4 notes data on the parents of these men. Most were from the lower classes (based on father's occupation), however, only 26 men said their parents were on welfare.

Only 367 of these men graduated from high school. Of these, 77 got an equivalency certificate. Only eight men graduated college.

Discussion

Psychiatry is involved in attempting to protect men who refuse to honor their obligations to society as well as the military. The antisocial character glibly blames others for his conflicts, successfully evoking guilt in authority, to evade

punishment and responsibility for his actions. The frequency with which physicians vehemently defended them was interpreted as evidence of tacit approval and permission by the physician for the character disorder to act out hostility to authority.

Dynamic understanding of motives of the character disorder shows a primary wish for revenge and punishment of the hated father, with attempts to trick him in a kind of game or challenge to accomplish casting the father in the role of the punishing person. This reflection of earlier parental relationships is designed to project responsibility to as well as demean authority, since the punishing father feels guilt at having to punish. Ambivalent object relationships were used to control others in an attempt to raise confusion and manipulate through a smokescreen of deceit. They played at appearing "borderline" to evade responsibility for their actions. There was uniformly no attempt to seek understanding of their behavior or motivation to change, only compensation for past wrongs done them.

Summary and Conclusions

This study has documented the nature of the personalities presenting to a psychiatrist in Vietnam. Conflict with authority was seen in almost every case. The psychodynamics of the conflict were discussed. Implications of this study are that psychiatric recommendations for control of lawlessness in a combat zone should include appropriate disciplinary limit-setting as a deterrent to the progressive breakdown in discipline seen with permissiveness in a combat zone. Drug abuse was seen as only one facet of conflict with authority.

Children's Health Center Names Anesthesiology Head

Dr. Hugh D. Westgate has been named the Director of Anesthesiology at Children's Health Center and Hospital (CHC) in Minneapolis. His appointment was announced by Dr. Arnold S. Anderson, president of the health facility, now under construction at 25th Street and Chicago Avenue. The Center is expected to be completed in December. Dr. Westgate will also be in charge of the Intensive Care Unit, Pulmonary Function and Respiratory Therapy function of CHC.

Psychiatry

Emotional Reactions of Children to Hospitalization

JOHN C. DUFFY, M.D.

In recent years the child who enters the hospital can be certain of a thorough clinical investigation, whatever his presenting problem, but may find his emotional needs unmet. Even our outstanding scientific pediatric services can place a child in a situation which is excessively impersonal, concerned too little with his feelings.

The emotional reactions of children to hospitalization may be crying, whining, or screaming; clinging tenaciously to his parents; eating or sleeping poorly; struggling against treatment; resisting taking medication; becoming tense and fearful, silent, sad. and withdrawn; exhibiting regressive or compulsive behavior; and being destructive of their environment and themselves.

Some children manifest emotional reactions to hospitalization *after* they have left the hospital. i. e.: (1) eating problems, (2) sleep disturbances, (3) enuresis or encopresis, (4) regression, (5) tics, (6) depression, restlessness, anxiety, (7) terror of hospitals, (8) death fears, (9) mute states, (10) hypochondriasis and (11) hysterical symptoms.

Theoretical Explanations

The literature on this subject for the most part has explored various possible explanations for the child's emotional response to hospitalization. The author will explore the following issues: unfamiliarity, separation, sensory-motor restriction, the child's concept of the hospital, age, family, parents, and other related issues.

If unfamiliarity is the key issue, psychological preparation of the child can mitigate the ill effects. The technique available to combat unfamiliarity by providing factual and realistic information to the child, encouraging emotional expression in the child, and establishing trust and confidence between the child and the hospital staff.

Dr. Duffy is Adjunct Professor of Psychiatry, University of Arizona Medical School, Tucson, Arizona.

See editorial, page 1136.

Provide Information

The task of providing information to the child is not simple. For the infant the brunt of information must be for the mother. The toddler, no longer totally protected by his mother, is still too young in development to grasp what happens to him, and can express his needs only in a primitive manner. The older child can understand what is to happen to him, why it will happen, and what he will experience. This information should be given simply, candidly, reassuringly, in detail appropriate to his general development.

Such information is necessary, for vague and undefined threats are more upsetting than a threat which is known and understood; just as unexpected stress is more upsetting than expected stress. If young children are not told the reason for hospitalization, they can get strange ideas about the reasons; for example they may feel they are being punished or being sent away forever because they have been naughty.

Timing

Timing any explanation of hospitalization for the child must be personalized probably between three weeks and three days before hospitalization. If the preparation is started too early, too much time is available for expansion and spreading of id fantasies. If preparation is done too late, the child's ego is given insufficient time to prepare its defenses. Although the mother is the ideal person to provide preparation for hospitalization, in some cases she may lack knowledge or be too anxious to be able to do the job. In that situation the task must be taken over by the nurse or doctor who finds the preparation was inadequate.

Environmental Manipulation

Environmental manipulations may make the the hospital less unfamiliar and forboding to the child, i. e. the child may bring a familiar toy or transitional object, the ward personnel wear street clothes instead of uniforms, etc. Such techniques achieve their effect by changing the general stimulus field while the preparation of the child places emphasis on changing the child.

Separation

For the pre-school child separation is traumatic because of a physical, psychological, and cognitive immaturity and dependence on his mother. The child's response to separation occurs in three phases: (1) protest, (2) despair, and (3) detachment. The initial phase, protest, may last from a few hours to a week or more. The young child is acutely distressed at having lost his mother and seeks to recapture her by the full exercise of his limited resources. He will often cry loudly, shake his cot, throw himself about and look eagerly towards any sight or sound which might prove to be his missing mother. Because his behavior suggests strong expectation that she will return, he usually rejects alternative figures who offer to do things for him, on occasion he may cling desperately to a nurse.

Despair

The phase of despair succeeds protest. The child's preoccupation with his missing mother is still evident, though his behavior suggests increasing hopelessness. He becomes quieter and may cry monotonously or intermittently. Withdrawn and inactive, he makes no demands on the environment and appears to be in a state of deep mourning. This quiet stage is sometimes, clearly erroneously, presumed to indicate a diminution of distress.

Signs of Recovery

The phase of detachment shows increased interest in surroundings, sooner or later succeeding protest and despair and is often welcomed as a sign of recovery. The child no longer rejects the nurses, accepts their care and the food and toys they bring, and may even smile and be sociable. Although this seems satisfactory, when his mother visits he may seem hardly to know her; instead of clinging to her he may remain remote and apathetic; instead of tears there is a listless turning away. He seems to have lost all interest in her.

Precautionary Treatment

Efforts at diminishing the trauma of separation have for the most part included: (1) visiting, (2) rooming-in, (3) arrangements to have the mother present during times of stress for the child. Liberal or unrestricted visiting hours normally beneficial can cause problems when an over-anxious and concerned mother is then in constant attendance to the child. Although rooming-in can make the hospital more like the family setting and is the natural thing to do, in many cultures the practical problems of space and expense limit its use. Having the parents present during examinations, painful procedures, before and after surgery, etc. is controversial.

Interpersonal Relations

The interpersonal interactions which take place in the hospital and may give rise to emotional problems can by grouped as child-staff, staff-parent, interstaff and child-child.

The child should have an opportunity for personal and direct contact with the staff. Contact limited to conflicts over rules, regulations and discipline is not adequate. Often overlooked is the effect of the child's personality on the staff who have their own emotional vulnerabilities. The key role the nurse plays in child-staff relations is not without risks for both the nurse and the child.

The nurse may identify with the child, perhaps by remembering her own childhood and her past fears in similar situations. If such feelings are acute, she may find the child's anguish too much to bear and she may react as an over-anxious mother not able to give the child the support and confidence he needs or to carry out treatment.

Doctor-Child Relationship

The child's personality can affect the physician in a different way. He may be uncertain as to how to provide the "human touch." Some things the doctor should do are: never discuss the child's condition in his presence unless in a positive fashion; be honest; keep the waiting time short before any painful treatment or other procedure; keep the parents informed; and make ward rounds friendly and informal in the child's presence.

In staff-parent relationships every effort should be made to deal with the parent's conflicts, confusion and anxiety in regards to the child's illness (not ignoring the role conflict between the nurse and mother).

Interstaff relationships which are marked by ambivalent feelings and competitiveness are destructive to the emotional health of the child.

The relationship between the children on the ward can be a very powerful force in effecting a healthy emotional climate. Children help each other face the realities of illness. Through active play, they are able to express and act out their feelings and are able to provide each other with reassurance to a far greater degree than any

adult.

Sensory-Motor Restrictions

Sensory-motor input is reduced during hospitalization. Sensory restrictions exist primarily in the lack of stimulation from people or things and motor restrictions are related to the limits imposed by bed or ward and lack of opportunities for recreation or education.

Child's Concept of Hospitalization

The greatest problem which blocks an understanding of the child's emotional needs is the adult's unfamiliarity with the child's subjective, irrational, and emotional approach to life. This must be considered in any effort to understand the child's concept of hospitalization. Most children from two to 14 years of age believe their behavior was responsible for their illness, a concept of crime and punishment, or guilt and retribution. For these children it follows logically that treatment should be painful. Other children who believed that someone else has caused their illness, for uncomprehensible reasons, nevertheless believe they are being punished. The heavy arm of morality escapes hardly a child. Children also have increased fears of death in conjunction with hospitalization, treatment, anesthesia and surgery. Not all distortions by the child are negative; some serve an important need in his defense mechanism.

Age

In general, children below five years of age are more susceptible to harmful effects of hospitalization than older children because of less social contact and experience, the reality of the mother-child interaction and separation, lack of communication ability and poor reality testing.

Family Relations and Prehospital Personality

The child's prehospital personality and the family's interpersonal relations play a significant role in the child's adjustment to hospitalization. A disturbed child prior to hospitalization may have significant adjustment problems. Parents bearing great anxiety or guilt in their attitudes associated with the child's hospitalization and illness communicate this to the child and may adversely affect the child's response.

Other Issues

There is no consistent correlation with the sex of the child. With regard to the level of objective stress, i.e. pain and discomfort or severity of the illness, the issue is not dependent on the type of seriousness of the illness or procedure, but rather on the type and depth of fantasies that are aroused. Such experiences as prior hospitalization, witnessing a frightening or painful medical procedure, and bodily exposure prime the emotional response.

Surgery

All surgical procedures are traumatic. In preparation of a child for surgery one should be knowledgeable of the special problem presented by the hyperexcitable child, the infant, the mentally retarded, and the emotionally disturbed child who faces serious problems in terms of their emotional adjustment. Such cases should have the benefit of the combined efforts of the pediatrician, surgeon and child psychiatrist.

> Dr. P. . . . had served in the Crimea, and seemed to regard a dilapidated body very much as I should have regarded a damaged garment; and, turning up his cuffs, whipped out a very unpleasant looking housewife, cutting, sawing, patching and piecing, with the enthusiasm of an accomplished surgical seamstress; explaining the process, in scientific terms, to the patient, meantime; which, of course, was immensely cheering and comfortable.*

On the Ventricles of the Heart

The heart has four ventricles, that is two lower in the substance of the heart and two upper (atria) outside the substance of the heart and of these, two are on the right and two on the left. The upper are separated by certain openings or gateways of the heart from the lower ventricles. The lower ventricles are separated by a porous wall through which the blood of the right ventricle penetrates into the left ventricle and when this right lower ventricle closes, the left lower opens and draws into itself the blood which the right provides.*

[da Vinci antedated William Harvey by a little over a hundred years. It is strange to the modern mind that da Vinci with his intimate knowledge of anatomy should accept the classical solution to the problem of transfer of blood from the right heart to the left through the impermeable ventricular septum. To da Vinci the septum was less of an obstacle to the passage of blood than the pulmonary artery which after all led nowhere but into an "impermeable" network of the lungs. In any event everybody knew that the purpose of the pulmonary artery and its branches was to carry air into the heart to cool it. Ed.]

*Leonardo da Vinci on the human body by C D O'Malley and J Saunders Schuman 1952.

"Death is the only thing that ever terrifies me. I hate it."

"Why?" said the younger man, wearily.

"Because." said Lord Henry, passing beneath his nostrils the gilt trellis of an open vinaigrette box. "one can survive everything nowadays except that. Death and vulgarity are the only two facts in the nineteenth century that one cannot explain away. Let us have our coffee in the music-room, Dorian."*

*Oscar Wilde: The Picture of Dorian Gray, 1891.

Where griping grief the hart would wound
And doleful domps the mind oppresse
There Musick with her silver sound
Is wont with spede to give redresse
Of troubled minds, for every sore,
Swete musick hath a salve in her store.*

Request for Physican's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers have received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Because of limitation of space, pictures oriented horizontally are preferred. All pictures will be returned if identified with the name and address of the physician. Please submit your pictures as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

Section 2 of Two Sections

The Development of Thoracic Surgery in the Upper Mid-West

THOMAS J. KINSELLA, M.D.

MINNESOTA MEDICINE
Volume 55, August, 1972, Supplement No. 2

Thomas J. Kinsella, M.D.
(1895-1969)

Thomas J. Kinsella, M.D.

Dr. Thomas J. Kinsella in his last years after retiring from the active practice of thoracic surgery, occupied himself with a compilation of local events that constitute "The History of Thoracic Surgery in the Upper Mid-West." This history, excerpted from his voluminous records, is now published as a Supplement to MINNESOTA MEDICINE.

He played a major role in the development of thoracic surgery in the Mid-West, and no one was more familiar with the progressive changes in surgical techniques, pulmonary physiology and advances in anesthesia. Some of us, who had the opportunity of working with him and observing his ability first-hand, were able to appreciate his tremendous perseverance and talent along with his complete devotion to specialized surgical endeavors.

Surgical therapy for pulmonary problems developed originally as an attempt to improve the dismal results of medical treatment of tuberculosis. Non-surgical treatment included prolonged periods of strict bedrest and the use of artificial or induced pneumothorax, pneumoperitoneum and with or without phrenic nerve operations. Sanatoria for patients with pulmonary tuberculosis became centers for various chest surgical procedures aimed at correcting complications of medical care and adding additional collapse measures such as extrapleural pneumothorax, oleothorax of various types and eventually thoracoplasty. Frequently multiple collapse measures were used in the same patient as one or another of the initial efforts failed in "arresting" the disease.

We recollect the earliest beginnings of thoracoplasty when the speed with which the procedure was completed supposedly determined success or failure for the patient. Dr. Arthur A. Law, who preceded Tom Kinsella as chief surgeon at Glen Lake Sanatorium, always used a stop watch to check his time and woe befell the assistants if more time elapsed than planned.

It remained for Tom to disprove the "speed" theory, which prevailed for many years. He demonstrated conclusively that patients had a smoother postoperative course when careful and meticulous anatomic dissection was performed regardless of the length of time required. This was true whether the operation was done under local or general anesthesia. Many old timers remember with amusement his personal dehydration training course in an attempt to delay certain vital functions whenever he planned a prolonged surgical procedure. At times a relief crew of nursing assistants became necessary because of exhaustion. Tom never seemed to tire.

When he left the Sanatorium to enter private practice, he transferred his clinical work to St. Mary's Hospital in Minneapolis although he continued to maintain the surgical program at the Glen Lake Sanatorium. Finally, resection of lung tissue became feasible due to increasing knowledge of pulmonary physiology leading to safer anesthesia, as well as increasing recognition of the importance of preoperative and postoperative care. Bronchoscopy, bronchograms and accessory surgical diagnostic measures led to further successful development of lung resection. These efforts were furthered by the discovery of chemotherapeutic agents which assisted in reducing and often eliminating surgical complications. These favorable events then permitted the extension of definitive thoracic surgical procedures to many other acute and chronic pulmonary conditions besides tuberculosis. While many of the improvements in surgical knowledge and techniques were used initially in lung surgery, they eventually led to remarkable progress in cardiac and other areas of major surgery.

Kinsella loved to teach. He was never too busy to explain the condition of a patient or his operative plans or his surgical technique to the youngest student nurse or the newest intern as well as to his medical colleagues.

Dr. Kinsella was a master surgical technician, but his surgical ability was enhanced by his experience in the medical care of patients with tuberculosis. His knowledge of total care led to a better understanding of all the difficulties in achieving satisfactory end-results and the value of team efforts in solving surgical problems.

The Development of Thoracic Surgery in the Upper Mid-West

THOMAS J. KINSELLA, M.D.

"Then the Lord God cast a deep sleep upon Adam: and when he was fast asleep he took one of his ribs, and filled up flesh for it. And the Lord God built the rib which he took from Adam into a woman: and brought her to Adam." Genesis 2:21-22.

THUS, DIVINELY conceived and executed was the first surgical operation and Thoracic Surgery established by the Supreme Anesthesiologist-Surgeon.[204] Now thousands of years later the practitioners of this surgical specialty have accomplished wonders, almost miracles. They even are accused of usurping the prerogatives of the Almighty. Be that as it may, the results obtained fall far short of the original operation.

Throughout the ages knowledge and experience accumulated slowly and intermittently with much loss in the intervening time. Drainage of purulent accumulations apparently came first. The Hippocratic[216] school in the fourth century B.C. recognized empyema and pyopneumothorax with its "Hippocratic succussion splash" and established drainage, even advising injection of air into the pleural cavity to facilitate removal of the pus.

Paul[306] of Aegina (625-690 A.D.) advised paracentesis but did not open the chest. Lanfranchi[228] of Milan in his Chirurgia Magna 1296 mentions operations for empyema. Andreas Vesalius[405] in 1562 successfully operated upon Carlos of Aragon for empyema and later reported two other successful operations. Purmann[319] in 1692 likewise advised incision of the chest for this condition. The ancient Japanese and also the Indians of the Great Lakes region are said to have incised with a clam shell knife for drainage of purulent accumulations in the chest, probably empyema necessitatis, and yet in 1835 Dupuytren,[92] the famous French surgeon, allowed himself to die from empyema, saying "he wauld rather die at the hands of God than at the hands of the surgeon."

Drainage and plastic operations for empyema thoracis and its complications constituted the vast majority of thoracic surgical procedures for many years. They were done by general surgeons with good results until the influenza epidemic of the first world war with its streptococcal and staphylococcal exudates changed the picture completely. The appalling mortality which followed the standard drainage operations previously used for pneumococcal effusions led to extensive studies which taught much concerning respiratory physiology and the mechanics of respiration. The report of the Empyema Commission and the monograph of Evarts Graham[138] "Empyema Thoracis" were particularly valuable.

The flood of articles in the surgical literature on special methods and techniques for treatment of empyema did much to confuse the average practitioner in spite of the stabilizing influence of Hedblom,[164] Graham,[140] Harrington[155,157] and others of wide experience in the thoracic surgical field. Most surgeons entering the thoracic field made their first publication on the treatment of empyema. Aspiration, followed by catheter drainage during the acute and sub-acute stage of the effusions, reduced the early mortality and became the standard and most successful treatment. In spite of everything, chronic cases still occurred.

Chronic Empyema

Unrecognized and inadequately drained empyemas and tuberculous empyemas over the years became the bane of the patient's (and the surgeon's) existence. Chronic suppuration, deforming scoliosis, multiple operations and amyloid disease added to the problems. Repeated rib resections usually did not result in cure. Early studies by Simon[373] in 1869, by DeCerenville[78] of Lausanne in 1877, and Estlaender[102] in 1879 were directed at the problem. The thesis of Julien Gourdet[136] of Nantes in 1895 did much to clarify the problem of obliteration of space in the chest in empyema as well as in tuberculosis.

These studies on cadavers were stimulated by an operation for empyema performed by Boiffin[37] in 1894. The very radical, deforming and the shocking Schede[357] flap excision of parietal pleura, intercostal muscles and ribs was often used but even then might not completely eradicate the empyema pocket.

Cornil[64] in 1891 noted that the power of the lung to expand was not lost even when encased in a thick "pleural peel." George R. Fowler[111] in October, 1891, operated upon a patient who had developed empyema following an attack of "Flu." He removed the fibrin mass, apparently freed the lung and excised the external fistula. Delorme[80] in 1893 reported a decortication but the patient died from shock and hemorrhage following surgery. Fowler[111] in 1893 in ignorance of Delorme's previous report first performed a successful decortication with a living patient. Ransohoff[324] noted that in incising the visceral pleural membrane, the underlying lung bulged through the incision on inspiration and carried out his "grid iron" procedure in 1900. Undoubtedly many procedures of many types were carried out over the years but never reported.

Empyema

Howard Lillienthal[245] in 1915 reported a series of 23 patients operated upon early in the course of the disease, incising the visceral peel, thus freeing the lung and the fissures with a 17% mortality. Following the first world war and the Influenza epidemic, Lt. Colonel William Keller[199] at Walter Reed Hospital did an excellent job of clearing up a large number of chronic empyemas, "surgical failures" collected from the armed services, and by many procedures rehabilitated many of them. Samson and Parker[303] in 1945 reported on military experience with infected traumatic hemothorax and showed 19 of 25 primary cures with primary healing. Parker[304] and Burford in 1948 had similar experience.

On the local scene Knute Hoegh[174] of Minneapolis in 1889 operated upon two patients by an Estlaender[102] type of procedure. C. H. Mayo[266] and Emil Beckman of Rochester reported in 1914 two cases treated by visceral pleurectomy done in 1911, and 1912. E. P. Quain[321] of Bismarck in 1920 performed a six-rib thoracoplasty on a seven year old girl with a chronic nontuberculous empyema but could not carry out any decortication because of excessive bleeding. Hedblom[164] in 1920 and Harrington[155] in 1925 reported on the Mayo Clinic' experience with empyema. For many years at the University of Minnesota Hospital Harry Ritchie[330] of St. Paul did excellent work in two very different and difficult fields—chronic empyema and Hare-lip-cleft palate. Wangensteen[417] in 1934-35 also made a report on the University Hospital' experience. The Minneapolis General Hospital and the Sanatoria of Minnesota and the Dakotas[206] provided this author with a considerable volume of nontuberculous and tuberculous empyemas. The clotted fibrinothorax (missed empyema) following antibiotic-treated pneumonias and the unexpandable lung following pneumothorax treatment of pulmonary tuberculosis as well as traumatic hemothorax produced a considerable volume of patients requiring decortication.

Anesthesia

The problem of anesthesia was always of prime importance to the surgeon undertaking thoracic surgery. Ether in adequate concentration obliterated the cough reflex and increased secretions both of which favored the spread and retention of bacterial-containing secretions disseminating tubercle bacilli as well as other infection. Chloroform for longer procedures was potentially quite toxic. Local anesthetics unless very skillfully handled were often unsatisfactory. Nitrous Oxide was a suffocation type of anesthesia and with the attendant cyanosis did not give adequate anesthesia or relaxation. The Carbon Dioxide absorber was added to the gas machines in 1935. The newer anesthetic gasses, Ethylene and cyclopropane, were an improvement and permitted better oxygenation but were explosive.

The intratracheal tube which had been in use since Meltzer[271] and Auer's report of 1909 was supplemented by pharyngeal packing so respiration could be controlled. The intratracheal cuff was introduced by Guedel and Waters[148] of Madison in 1937.

Ether in oil per rectum and Avertin per rectum were used. Evipal by vein for short procedures came in about 1933-34 followed by Sodium Amytal which gave too long a narcosis.

Pentothal Sodium (Thiopentone) was introduced into clinical use by Lundy[257] of the Mayo Clinic and Waters of Madison in 1934 as a more satisfactory agent.

Walter Raleigh in 1595 mentioned the South American Indian arrow poison from which Curare is derived. Arthur Lawen[234] in 1912 used some in an attempt to reduce the amount of ether needed to produce relaxation in abdominal surgery. Griffith[145] and Johnson of Montreal in 1942 used Curare to give relaxation. With the introduction of relaxing agents, Curare, Intercostin and Detubo Curare to intravenous solutions, intravenous anesthesia became available for thoracic surgery.

As the problem of anesthesia became more complex, the need for physicians to take over the work became increasingly apparent. The pioneers Guedel, Beecher, Waters and Cullen stand out. On the Minnesota scene we find the names of Lundy,[250] McCuskey, Tovell, Touhy, Seldon and Matthewsen from the Mayo Clinic,[312] and from the Twin Cities, Knight,[212] Cole, Baird, Friend, Van Bergen, Crowley.[70] Anesthetic machines were developed and improved to aid in control of the various agents and combinations thereof. The Heidbrink of local manufacture and especially the Lundy improvements were of particular value.

Dr. John S. Lundy[312] was brought to the Mayo Clinic by W. J. Mayo from Seattle in 1924 and became the head of the section of anesthesia and developed it to its superb state. Previously anesthesia, usually ether, was administered by specially trained nurses for many years. Dr. Lundy had been preceded from October 1, 1920, to September 29, 1921, by Labat[312] special lecturer in regional anesthesia who was brought over from Paris by Dr. C. H. Mayo for that purpose. His book "Regional Anesthesia"[225] published in 1922 is still a valuable reference book and a treasured volume in any medical library. Lundy[257] in 1929, organized the Anesthetists Travel Club which in 1952 became the Academy of Anesthesiology, the latter word coined by Paul M. Wood of New York. He was delegated in 1933 to take over transfusions in children and later that same year that service for all patients. He began refrigerating citrated blood in 1935 in Dr. W. C. McCarty's pathology laboratory refrigerator and established the first Blood Bank in the country, a year before the Blood Bank was started at Cook County Hospital. This Division was later taken over by Dr. T. H. Seldon[312] and later by Dr. Matthewsen.[312] Under such direction anesthesia for all types of surgery became outstanding and many physicians were trained under their direction.

The Twin Cities had similar problems in anesthesia. Chloroform, then Ether and later Nitrous Oxide, expensive at first and suitable for short periods only, was administered by a nurse or some physician who was free at the time. Robert Emmet Farr[104] an early advocate of local anesthesia performed almost every type of surgery under local anesthesia aided by soft music from a phonograph. His book on "The Techniques of Local Anesthesia" published in 1923 contains much valuable material. His associate, Dr. Stanley Maxeiner[262] carried on the work. The nurse anesthetists did a marvelous job with the drugs and equipment available but worked under handicaps. The early thoracoplasties at Glen Lake Sanatorium started by Dr. Arthur A. Law[131,233] in 1922 were done under intercostal block and light Nitrous Oxide with extreme speed but with much shock and reaction. Soon after I took over the surgery at the Sanatorium in 1928, I was confronted with a severe diabetic patient with a large pulmonary cavity and before Insulin was available, I carried out a three stage thoracoplasty under local infiltration anesthesia and intercostal block in the field with good results and without the patient missing a single meal in the postoperative period. Subsequently all thoracoplasties were done by a similar technique with low mortality and much less blood loss and shock, and a much smoother recovery. In one series of over 1500 stages of thoracoplasty only two transfusions were given.

Dr. Ralph T. Knight,[212] returning from service in World War I, became instructor in surgery at the University under Dr. A. C. Strachauer, following James W. George, a general practitioner who as a part-time instructor had done some teaching about 1920 using chloroform and ether.

Blood pressure recording was introduced in 1923. Nitrous Oxide was used only occasionally because of its high cost. The carbon dioxide absorber was added in 1925 and Ethylene in 1926. Ann Whelan (Arnold) was added to the staff as instructor in August, 1927. Dr. Knight[213] became director of anesthesia for both the University and Minneapolis General Hospitals and their school for nurse anesthetists in 1930. Avertin per rectum was added in 1929-30 and Cyclopropane displaced all others except when cautery was to be used. By 1935 controlled respiration and induced apnea for special situations was added

as suggested by Guedel.[149] During 1933-34 Evipal for short procedures and Sodium Amytal and Sodium Pentothal were used more and more, though much surgery was done under Nitrous Oxide and ether. Spinal anesthesia was administered for many upper abdominal cases using Procain and some Nupercain. Early in 1939 a fatal Cyclopropane explosion occurred at the University Hospital[401] at the termination of a thoracoplasty operation again calling attention to the dangers of using a flammable anesthetic and directing attention to intravenous anesthetics. Intratracheal insufflation as recommended by Meltzer[271] and Auer in 1909 was in common use but for controlled respiration, pharyngeal packing was used in order to obtain a gas seal for positive pressure inflation of the lungs. Waters[148] of Madison re-introduced the inflatable cuff intratracheal tube in 1937. This improvement plus intratracheal suction for removal of secretions were of great help in thoracic surgery. My first three lobectomies for bronchiectasis at the Minneapolis General Hospital, the first in the local area in 1937, were done with nurse anesthetists and without intratracheal tube or suction and why the patients recovered without complications is a mystery.

Knight's[213] first private anesthesia patient was one of mine, a 64-year old man with bronchogenic carcinoma, upon whom we did a right total pneumonectomy, 1937, at Northwestern Hospital,[293] the first successful one in Minnesota. He survived 13 years and nine months, dying from hypertensive cardiovascular disease without recurrence of carcinoma. We engaged Dr. Knight for every chest case from then on. His school for anesthesiologists and accessory school for anesthetists developed as he added to his staff. Dr. Cole[212] first joined the staff and Dr. Baird, then Dr. William Friend and later others. As his staff grew he extended anesthesia coverage to Ancker and Miller Hospitals in St. Paul, St. Mary's and Veterans Hospitals, Northwestern and Deaconess in Minneapolis. Dr. Cole left the group in 1943 for St. Mary's Hospital in Duluth to become the first Anesthesiologist in the state outside of Rochester and the Twin Cities. By 1946 there were under Dr. Fred Van Bergen[213] 18 residents in anesthetic training at the University and affiliated hospitals. Gradually the general surgeons who at first were reluctant to use physician-administered anesthesia recognized the importance of it to the extent that now the large hospitals may have as many as six to seven anesthesiologists busy at all times. Dr. Knight retired in 1954. Dr. James H. Crowley,[70] a Rochester-trained anesthesiologist, took charge at St. Joseph's Hospital, St. Paul, in 1948 and has continued to date.

Without the pioneering efforts of Lundy, Knight and Crowley, thoracic and cardiovascular surgery in Minnesota could not have developed as they have and general surgery owes an equal debt to these men. As the thoracic operations became more extensive and complex, and cardiovascular procedures and open heart and transplant operations came into the field, the duties of the anesthesiologist became more demanding.

Intratracheal Tube

Robinson[332,333] and Brauer in 1908 showed experimentally that under a steady air flow with both pleural cavities open and no lung motion, surgery could be carried out for two to four hours but there was a carbon dioxide build-up. Meltzer[271] in 1909 demonstrated that the lung could be aerated through an intratracheal tube with escape of air along side the tube with no lung motion. Robinson[337] in 1912 developed an apparatus with positive pressure for intratracheal anesthesia with ether by closed mask without the tube and also via intrapharyngeal, intrabuccal and intratracheal administration. He moved to Europe in 1913 to work with Sauerbruch in thoracic and experimental surgery. He returned to the United States to the Mayo Clinic[312] in 1915, to become head of the newly created section of Thoracic Surgery.

Karl Connell in 1912 advocated pharyngeal insufflation, a method adapted to thoracic surgery by Branower in 1913. The carbon dioxide absorber was added to the gas machines in 1925. Induced apnea was introduced in 1935 by Guedel.[148] The cuffed intratracheal tube was introduced by Waters[148] of Madison, Wisconsin, in 1937, enabling the anesthesiologists to better control the anesthesia and lung secretions. The cuffed tubes were not commercially available for some time. The homemade version with a somewhat more rigid cuff was responsible for the loss of a child who had a lower lobe lobectomy for bronchiectasis in 1939. A local slough of the tracheal mucosa from unrelieved pressure and

death from suffocation followed.

The value of the intratracheal tube is well illustrated by two of our early surgical patients. The first was a 20-year-old girl with extensive unilateral bronchiectasis since childhood, from whose trachea Knight aspirated well over a liter of pus during a pneumonectomy.[351] The second was a man who had profuse pulmonary bleeding from a metastatic synovioma in the lung pouring out over 750 cc of blood into his trachea in the time it took to open his chest and clamp the lower lobe bronchus.

The double lumen catheter of Carlens,[47] Gebauer[124] and others for bronchospirometry not only allows selective pulmonary function studies but affords better control of respiration in patients with profuse secretions or hemorrhage, or situations requiring bronchial plastic or transplantation procedures.

Pressure Chamber - Intratracheal Anesthesia

Ferdinand Sauerbruch[275] became assistant to Von Mikulicz at Breslau in 1903. By 1904 he had developed a negative pressure chamber for experimental work on dogs. The first chamber would accommodate two persons for surgery but within two hours the temperature within it became too hot for comfort. Later the chamber was enlarged with 14 cubic meters of air and would permit five people to work within it. Sauerbruch, sponsored by Von Mikulicz in 1904 demonstrated this chamber before the German Surgical Society, reporting that they had performed thoracic operation on 78 dogs without mortality using a negative pressure of 10 mm of mercury. Dr. H. Willy Meyer[273] of New York visited Breslau later in 1904 and was privileged to observe the surgery—a transthoracic resection of the esophagus on a dog. Resections of the esophagus were later carried out on 10 dogs in a larger chamber. The first human operated upon for a carcinoma of the esophagus in the larger chamber died during the procedure. The next patient survived the removal of the mediastinal tumor. A number of positive pressure cabinets were developed in Europe. Brauer[275] of Heidelberg developed a mask-type but preferred the negative pressure type. Robin, Matas and others overcame the tendency for the lung to collapse when the chest was opened by blowing air into the trachea. Von Mikulicz died of cancer in 1905 and was followed at Breslau by Prof. Garre. Sauerbruch was then transferred to Greifswald under Dr. Friedrich. They moved to Marberg in 1907 and there continued their experiments.

Sauerbruch appeared before the Surgical Section of the American Medical Association in Chicago in 1908, reading a paper and demonstrating his negative pressure chamber. He was the guest of Dr. Herbert Willy Meyer[275] and after the meeting returned to New York with him, presenting the chamber to Dr. Meyer. It was installed in the Rockefeller Institute, where he operated upon a dog with Dr. Meyer assisting. By the fall of 1908, Dr. Meyer and his brother, a mechanical engineer who had studied all of the available machines in Europe constructed a larger chamber for both positive and negative pressure use. Subsequently another and much larger commercial chamber was built in May, 1909, and used experimentally and clinically until 1923. With the development of closed-mask and intratracheal anesthesia, the negative pressure cabinet was no longer needed and so was abandoned for clinical surgery.

Blood Bank

The first transfusion (Hoff[175]) for a human being is reported to have occurred in Paris in 1667. An edict from the Criminal Court of Paris was issued in 1668, forbidding further transfusions in man until approved by the Faculty of Medicine of Paris. Lower[175] of Oxford, apparently was the first to conduct experimental transfusions in animals in 1665 replacing the blood removed with equal volume of beer and wine and later blood from another dog. The experimental work of Denis[175] and Emmerez of Paris in March, 1667, included dog-to-dog transfusion, calf-to-dog, sheep-to-boy and sheep-to-man without difficulty. One man received two transfusions without reaction but died the next day. A hemiplegic woman also a mental case received two transfusions and apparently improved. Apparently no human-to-human transfusions were done.

The importance of available blood for transfusion cannot be over-emphasized when many thoracic surgical procedures are to be undertaken. The blood loss can be considerable and unavoidable, adequate replacement is mandatory. Sporadic attempts at blood transfusion occurred for many years, often with disastrous results. Landsteiner in 1900 grouped patients and donors, thereby reducing the risk of reaction. Hustin[175]

of Belgium in 1914 introduced the use of citrate and glucose for transfusion. Robertson[175] of England in 1918 was the first to preserve citrated blood. Transfusions were not then commonly used. As an intern at Minneapolis General Hospital in 1919-1920, I well remember direct transfusion by syringe transfer and indirect by the use of the paraffin tube method. Later relatives and friends were held around to be bled as the occasion arose. There came a time when it was positively dangerous for friends and relatives to visit a patient at the University Hospital for they were sure to be captured and bled. Walking blood banks were organized in many communities among the police and firemen, lodge members and civic groups for emergency use. Lundy[257] of the Mayo Clinic began to store citrated blood in McCarty's pathology laboratory refrigerator at St. Mary's Hospital, Rochester, in 1935, thus establishing the first Blood Bank a full year before the Cook County Hospital Bank was established. The Rochester walking blood bank had been in use for many years on a pay-for-donation basis, one man setting a world record of 214 donations over a period of 36 years.

Locally before undertaking an extensive intrathoracic surgical procedure, it was necessary to have a half dozen suitable donors at hand before starting the operation or have them bled immediately before starting. I vividly recall in 1939 at Abbott Hospital undertaking the removal of a huge intrathoracic neurofibroma which proved to be very adherent, with severe blood loss. When we had given four units of blood it became evident that we could not complete the excision with the two units of blood still available. The field was packed and a call sent to the patient's brother who was a captain of police. Within minutes we had a dozen husky policemen, group IV donors, at the hospital. The resection was completed without incident: the patient recovered.

Our problem at St. Mary's Hospital,[351] Minneapolis, was complicated by the fact that many of our patients were from out of town, many from the Dakotas, Montana, and Wyoming.

This problem was met by having the referring physician cross-match the patient and relatives and friends, and then bleed six suitable donors and send the six bottles in ice down with the patient two days before the scheduled operation with two vials of blood attached to each bottle, so our laboratory could carefully recheck each unit with the patient before using it. We were careful to explain beforehand that any excess blood not given to the patient would be placed in a pool to be used in emergencies and for Indians and county patients who could not furnish their own. In this way there were times when we had as much as 20-30 unit credits in the refrigerator, but it was usually used up promptly by the numerous Indians we were operating on for the Indian Bureau and the State Sanatoria of Minnesota and the Dakotas. St. Mary's Hospital, Minneapolis, established its own Blood Bank[351] in 1943 under Dr. R. Koucky, our pathologist. This permitted us to transfer patients from other local hospitals which did not have their own banks.

Minneapolis through the Junior Chamber of Commerce organized the City-wide Blood Bank in 1946 on a small scale. The War Memorial Blood Bank[277] began in 1948, simplifying our problems very materially. The development of the Rochester Blood Bank must be credited to Mathieson[312] while the War Memorial Bank, Minneapolis, is to the credit of Matson.[260] In 1961 in Rochester 21,000 units of bloods were processed and over 36,000 units in 1965 in Minneapolis. The growing cardiac surgery load will probably increase this materially. The Minneapolis Bank[277] in 1967 processed just under 45,000 units.

Clinical Laboratories

The early laboratory studies for chest surgery in the twenties were quite minimal. Blood and urine examinations were usually sufficient for most cases with a few additional studies in special circumstances. As the surgical procedures became more extensive and more complicated, as additional diseases and conditions were accepted for surgical relief, and older and more debilitated patients subjected to operation, much greater demands were made on the laboratories for help and guidance in the treatment. A simple hemoglobin, white count and differential were inadequate. Special cell type studies, reticulocyte count, iron studies, cross-matching including the minor groups, Rh factors and sensitivity, blood metabolites and electrolytes, blood gasses, antibiotic levels, and a host of others became available and were used extensively. The electrocardiogram is no longer three leads but

multiple tracings with exercise and various stress factors added. The single total vital capacity no longer suffice, but timed studies, rates and other factors are studied. Sputum smears alone are not enough but cultures, sensitivities to antibiotics, cell studies for malignant cells are needed. Radioisotope studies, liver and kidney function studies are all available to aid the physician and surgeon. They help the physician but at the expense of the patient, for the laboratory bills are frequently appalling. Automation has helped some with batteries of tests done at little added cost, but the teaching methods today which require a complete survey of everything on every patient has contributed much to the skyrocketing cost of medical and hospital care. Tools can be used but they are often abused.

The clinical pathologist has developed and expanded with his domain and has been alerted to new techniques added to his laboratory. In the thirties our one pathologist at St. Mary's could cover everything, and during the war years covered three other hospitals in addition. Now with three full-time men, they are busy all the time. Without the guidance of these men, thoracic surgery and other specialties could not have functioned and developed to their greatest potential.

Xray

Without a doubt the single most valuable tool available for discovering, diagnosing and guiding the treatment of chest disease has been the Xray. Some consideration of its discovery[233] and development seems necessary in any history. Geissler[129,144] in 1858-59 made the first vacuum tube. Hettorf in 1860 noted that the luminous stream —cathode rays—from this tube was deflected by a magnet. The work of these two was followed by the experiments of Crookes[67] with a higher vacuum tube. The glow disappeared and these rays were intercepted by a metal plate. Hertz[233] in 1892 noted that the rays penetrated thin gold leaf and other thin metal. When he died, the experiments were carried on by Prof. Lenard.[233] The rays penetrated many substances and would excite fluorescence from barium platino cyanide and other substances. In 1895 W. K. Rontgen,[129,344] Professor of Physics at the University of Wurzberg, Austria, noted that paper coated with barium platino cyanide fluorescenced brightly even though the tube was cardboard-covered. The rays could not be deflected or refracted and were much stronger than the cathode rays. He experimented with photographic plates wrapped in paper and produced pictures of metal objects and the bones of the hand. When presenting this finding at the December, 1895, meeting of the Wurzberg Physio-Medical Society he claimed that he had discovered a new kind of ray which he called "X" for the unknown.

Rontgen's discovery of Xrays became one of the most important factors in the diagnosis and treatment of disease of the chest. Potain[283] in 1897, in Paris, before the Academy of Sciences demonstrated pictures which were purported to be the first two pictures of the chest made by Xrays.

Pupin[283] in 1896 made the first radiographs of the chest in the United States, placing a fluorescent screen between the patient and the photographic plate. John B. Murphy[283] in his presidential address to the American Medical Association Meeting at Denver in 1898 showed x-ray pictures of the chest. Mach and Thomson[144] in April, 1896, first used the steroscopic technique in radiography. Bleyer, Battelli and McIntyre[144] in July, 1896, first used the photo fluoroscope. Bucky[129] developed his grid in 1915 to be improved by Potter in 1919 as the Potter-Bucky diaphragm. The principles of body section radiography were first outlined by Bacage[129,144] between 1917 and 1921. Vallebona[129,144] in 1930 reported his technique which he called stratigraphy. There followed other techniques called planigraphy by Ziedses des Plaines[129] in 1931, Tomography by Grossman[130] in 1935, and Laminography by Kieffer[130] in 1938.

Sicard and Forestier[372] reported making bronchograms with lipiodol in 1922. Berberich and Hirsch[129] in 1923 reported the first arteriogram and venogram in man using 20% Strontium bromide. Forssman[110,129] in 1926 catheterized his own heart. Moniz, Calvalho and Lima[130] in 1931 demonstrated the pulmonary vessels in man with sodium iodide. Castellanos, Pereiras and Garcia reported the first roentgen contrast demonstration of congenital cardiac abnormalities in 1937.

Goodspeed[134] from the Physics Laboratories of the University of Pennsylvania accidentally made an x-ray photograph on February 22, 1890, six years before Rontgen's discover, but claimed no credit for the discovery. Morton[233] of New York was the first to produce a photo with the Holtz

machine in which the static-induced current from a Rhumkorf coil is coupled to the tube and outer coating of a Leyden jar and regularly interrupted by a system of rods.

Two months after Rontgen reported on his development of the Xray, Dr. John Grosvenor Cross,[69] an independent practitioner in Rochester, Minnesota, bought an x-ray machine for his office in February, 1896. He demonstrated its used before the Southern Minnesota Medical Society in August, 1896, and in 1897 before the Olmsted and Wabasha County Medical Societies. Blake[406] of Kansas made an x-ray picture of his hand on February 11, 1896.

The rapidity with which Xray was accepted about the country is illustrated by a news item in 1896, which reported that in an Iowa[433] suit for malpractice in a fracture case, the trial was postponed until Xrays were obtained. Surgeons were prompt to recognize the value of this new tool and to use it in their practice, notably Dr. A. A. Law and Dr. Geist in Minneapolis, Drs. Arnold Schwyzer and H. J. O'Brien at St. Joseph's Hospital in St. Paul, and Dr. Arthur Colvin at City and County Hospital and later at St. Luke's in St. Paul.

C. H. Mayo[264] in January, 1897, brought to Cross a small boy who had swallowed a vest buckle. Two skiagraphs were made by a twenty-minute exposure, demonstrating the buckle in the cervical esophagus, from which it was removed through a cervical esophagotomy by Dr. Charlie Mayo.[264] During the next three years, Cross did considerable work for the Mayos for fractures and foreign bodies. Soon he was receiving referred patients from the Twin Cities. He sold his practice to Dr. Crewe[60] of Rochester and then spent two years in study in Vienna in internal medicine and upon his return, moved to Minneapolis in 1902. His thesis for admission to the Minnesota Academy of Medicine in 1901, was entitled "Present Status of Xray in Medicine and Surgery." We can find no reports of x-ray work by Dr. Cross in Minneapolis where he was an internist and on the Medical School Faculty.

The Mayos purchased an improved type of x-ray machine in 1900. This model was also equipped with flashing lights and jumping sparks which did not appeal to Dr. Will, who soon had these outlets plugged with wooded pegs. Dr. Charlie[60] did considerable work with it and sustained injuries to his fingers in the process. Dr. Christopher Graham[60] later was in charge as part of the laboratory section and made attempts to study chest and other organs.

The first local diagnosis of carcinoma of the stomach by x-ray means was made at the Mayo Clinic in 1909 by Willey, working with Plummer, who also sustained x-ray injury to his hands. The department did not come into its own until Dr. Russell D. Carman[312] took over in January, 1913. Dr. Charles G. Sutherland[312] became first assistant in radiology October 1, 1918, and Dr. Alexander Moore[312] became head of the section in 1926 upon Dr. Carman's death. Dr. Byrl R. Kirklin[312] became head of the section in January, 1930. Harry M. Weber[312] was first assistant in roentgenology and associate in 1931. Leda J. Stacy was the head of the Radium therapy in 1915 succeeded by Harry Bowing[312] in 1919.

Drs. Stephen A. Kiefer and Eugene Gedgaudas, reporting on the history of the Department of Radiology of the University of Minnesota in Myers'[285] "Masters of Medicine," noted that within six months of Rontgen's report of the discovery of Xrays, the University student newspaper "Ariel" reported that "Professor F. S. Jones' new Fluoroscope and Crookes tube had arrived and both proved to be all that was expected," and later on October 24, 1896, reported that Professor Jones, of the Department of Physics of the University of Minnesota, on October 23 at the request of Dean Millard had at the City Hospital in St. Paul located bullets in the legs of two patients with the aid of an x-ray machine. It also notes that he had made an x-ray photograph of a hand with a five-minute exposure. These pictures are not the first in the Twin Cities for Dr. Law[233] had demonstrated a number of x-ray photographs before the Minnesota State Medical Society meeting of June 18, 1896.

Xrays in Minneapolis

Dr. Arthur Ayer Law,[233] then associated with Dr. Frederick A. Dunsmoor, the outstanding surgeon of the city, on June 18, 1896, before the Minnesota State Medical Society delivered a paper entitled "The Xrays," in which he discussed the origin of the discovery and its development, and demonstrated some skiagraphs which he had made, and listed some of its possibilities. He reported having made skiagraphs of needles, pieces of glass, bullets, even through the chest,

fracture callous, and tuberculosis of the os calcis, tumors of the extremities and uric acid deposits. He used both the fluoroscope and skiagraph and noted that cholesterol gallstones and oxalate kidney and bladder stones cast little shadow which precluded their being so diagnosed. Phosphatic stones were more resistant to the ray and uric acid the most resistant. Early exposures varied from 15 minutes to two hours. This paper was published as the lead article in the *Northwest Lancet,* 17:6-8, 1897. His second paper given before the Minnesota State Medical Association Meeting on June 18, 1897 appeared in the same volume.[232] He reported on 15 months of experimentation without ill effects on himself. (This would mean he had a machine at least by March, 1896). He discussed the many improvements in equipment since originally introduced with exposures reduced to three to ten minutes. His early work was done with a large Holtz machine but later with the Tesla addition.

Arthur Law in a letter dated September 18, 1898, from the Philippines[119] wrote: "We are short of Doctors—every man already has charge of from 60-80 sick. The hospital is fairly well supplied with most of the necessities. A large x-ray machine is here and is my special charge."

For many years Law maintained x-ray equipment in his and Dunsmoor's office for his own use. A staff list of Asbury Hospital for 1904 listed Dr. A. A. Law for Xray and surgery.[308]

Dr. Charles D. Harrington[154] had a Noth x-ray coil machine in 1897. He loaned the coil to St. Barnabas Hospital, the oldest hospital in the city in 1899. Northwestern Hospital also added equipment in 1899.

Dr. Charles A. Erdman[101] in 1900 published an extensive study of the anatomy and mechanisms of the wrist joint. The x-ray pictures were of his own wrist made by D. C. Cole, then a medical student at the University.

Dr. Ray Knight[214] and Dr. Woodward had had a static machine since 1909. They added an 18-inch coil in 1910-11 and in 1913 added the first advanced Snook apparatus in Minneapolis which subsequently was sold to the Medical School to start the Xray Department. It was later turned over to the Dental School where it was used until 1949. The radiologists of the period were: Harrington, Spring, Donaldson and later Bissell.

Robert G. Allison[8] came to Minneapolis in 1920 as Assistant Professor of Radiology at the University and opened a private office for radiology. He had been in radiology at Trudeau Sanatorium, at Cornell University and under Col. Lewis G. Cole of New York. He had been radiologist at Harper Hospital in Detroit and the Municipal Tuberculosis Sanatorium in Chicago. While in charge at the University, the George Chase Christian Memorial donation to the Cancer Institute provided 200 mgms of Radium in tubes, one half gram of Radium in solution for the Radon plant and a 200 K.V. x-ray therapy unit. This later was permitted to remain idle and unused until Dr. K. W. Stenstrom arrived in June, 1926, and took over the radiation section. The two sections were separated in 1937 with Dr. Leo G. Rigler in charge of Radiology. A second high voltage 400 K.V. therapy machine was added in 1942 as another gift from Mrs. Christian. Mrs. Archie Walker in April, 1953, donated a 1,000 Curie Cobalt 60 therapy installation, the second unit of its type in the United States.

The Xray Department at St. Barnabas Hospital for a three-month period in 1903 reported expenses of $18 and an income of $84. As late as 1916, the total income of the department was $2,200.

Early Thoracic Surgery in the Twin Cities

When this author left full-time work at Glen Lake Sanatorium in September, 1936, for private practice in Minneapolis, there was no established field of Thoracic Surgery. The volume of work available was small, consisting of surgery for empyema, for tuberculosis and administration of Pneumothorax. Even the Mayo Clinic did not have sufficient volume of chest surgery to keep one surgeon busy. The field was expanded by a slow gradual process of development of techniques, instruments, and methods of handling and care. As the lone surgeon with interests along this line in the city and wide surrounding territory, there were times when it was not unusual to have patients in seven or eight different hospitals at one time, requiring much traveling for hospital calls and dressings and much transporting of all special instruments and equipment. It was not until after the end of World War II that training programs in surgery produced men interested in this field and trained in chest work that others entered the local practice of chest surgery. Gradually a number of well qualified men entered the field which now is well covered:

Drs. N. K. Jensen, W. R. Schmidt, Frank E. Johnson, Joseph A. Garamella, Michael F. Lynch, Aydin M. Bilgutay, William D. Kelly, Paul Gannon, Charles A. Peterson, Theodore A. Peterson, Jerome T. Grismer, Richard E. Larson.

In St. Paul Dr. D. Greth Gardner was the pioneer following Dr. Lou Daugherty, then Drs. N. Logan Leven, Lyle Tongen, Bernard G. Lannin, Samuel W. Hunter, Bernard Goott and Coleman J. Connolly.

American Association for Thoracic Surgery

The American Association for Thoracic Surgery was founded in New York in 1917, as an outgrowth of the recently organized New York Society for Thoracic Surgery, which was the first such Society in the World. Willy Meyer had sensed the necessity of bringing together a group of men interested in problems of thoracic disease and the need for a place to discuss the many problems of this infant surgical specialty. Membership was not limited to surgeons but included allied specialties related to thoracic problems including allied specialties related to thoracic problcluding: Internists, Phthisiologists, Endoscopists, Roentgenologists and Pathologists. The Charter Member Group of fifty names was widely distributed but contained five from Minnesota: Dr. J. Frank Corbett and Dr. A. A. Law of Minneapolis, Dr. William Lerche of St. Paul, Dr. Walter Boothby and Dr. Samuel Robinson of Rochester. Another Dr. Kenneth Bulkley who was the original secretary of the New York Society later moved to Minneapolis and became associated with Dr. Law in October, 1921. Within the next year, three more Minnesotans were added—Dr. Henry S. Plummer, Dr. Frank C. Mann and Dr. Carl A. Hedblom, all of Rochester.

From this group Dr. Corbett did no chest surgery except for empyema unless it might have been in service, his interests being in experimental work and later in Neurological surgery. Dr. William Lerche was primarily interested in bronchoscopy and esophageal work though he did operate for mediastinal abscess and esophageal perforations. Dr. Walter Boothby was not a surgeon, but did much work on metabolism and oxygen therapy with the B. L. B. (Boothby Lovelace Bulbulian) mask for aviation and clinical use. Bulkley after coming to Minneapolis assisted Law for a time but did little chest work. Henry Plummer was an internist, interested in esophageal disease and contributed much to the diagnosis and treatment of conditions affecting it. Frank Mann was an experimental physiologist and surgeon. He was a superb surgical technician and through the Institute at Rochester which he headed, taught many of the staff and fellows the intricate techniques necessary in their various problems. Drs. Law, Robinson and Hedblom were clinical surgeons and all three pioneered in the thoracic field.

Under the editorship of Dr. Evarts Graham, the *Journal of Thoracic Surgery* appeared in 1931 as an independent Journal published by C. V. Mosby of St. Louis, later changing its title to *The Journal of Thoracic and Cardiovascular Surgery*.

The Board of Thoracic Surgery was founded in 1948 as a subsidiary to the American Board of Surgery in order to certify the men experienced in surgical disease of the chest. To provide a meeting forum for many of these young men, the Society of Thoracic Surgeons was founded in 1964. Many other papers on chest surgery are to be found in the *American Review of Tuberculosis and Respiratory Diseases and Diseases of the Chest and the British Journal-Thorax*.

Bronchiectasis

Bronchiectasis, bronchiectatic abscess and true pulmonary abscess were not sharply differentiated in the earlier literature. The clinical picture of extensive chronic bronchiectasis was easily recognized but the earlier stages were not even with x-ray studies. Bronchoscopy was of some help. Attempts at bronchial visualization with opaque powders such as bismuth were not too successful. It was not until 1932 when Sicard[372] and Forester brought out iodized oil (Lipiodol) that good visualization of the bronchial tree was accomplished, and the exact extent of involvement demonstrated. Medical management, postural drainage, cough mixtures, vaccines and climatic change often helped temporarily. Instillation of iodized oil at times gave some help. Later antibiotics did help materially as did nebulized antibiotics to control infection during acute exacerbation but did not remove the dilated bronchi or prevent complications. For many years surgery had sought a cure for the condition. Between 1837 and 1880 Richards, Forde, Hall and Grinnell each reported a case of excision of a herniated portion of lung through a chest wall with recovery. Gluck[283]

Sehmidt, Block[283] and Biondi[30] and others in 1885 showed that partial resection of the lung was possible in animals. Heidenhain[169] in 1898 successfully removed a left lower lobe for bronchiectasis and recorded two previous operations for drainage of bronchiectasis with rib resection. Doyen[89] in 1898 successfully removed the remains of a right lower lobe previously drained for a hydatid cyst. Dr. C. H. Mayo[265] in 1898 reported three cases of pneumonotomy with two deaths and one recovery. Krause[217] in 1899 did a partial lobectomy with recovery.

Lung resection continued to carry a very high mortality. Samuel Robinson[332] and others experimentally proved in dogs that lobes of the lung could be removed with a high degree of success. The dog's lungs were not infected while the lungs of patients subjected to resection were badly diseased. As late as 1916, Dr. Robinson[340] made the statement: "Let no man attempt a lobe excision in a single operation in man." Even when done in stages there was a very substantial mortality.

In spite of many disappointments a few brave pioneers persisted in their efforts to relieve patients of this "loathsome" disease. W. Meyer,[274] Lillienthal, Robinson and others struggled to find the answer. Meyer[274] in 1914 reported a 50% mortality in 16 pneumonectomies. Robinson[336] in 1917 recorded one death in five lobectomies done in one to three stages. Lillienthal[248] by 1922 reported a 42% death rate in 14 lobectomies by mass ligation technique. Graham[137] in 1923 introduced his Cautery "Lobectomy" drainage for bronchiectasis reporting a 20% mortality in 20 patients.

Quencke[322] in 1888 and 1896 successfully carried out extrapleural thoracoplasty for bronchiectasis with good effect. Spengler[41] in 1890 advocated the same. DeQuervain[83] advised lobectomy after thoracoplasty. Mumford and Robinson[336] did three lobectomies after thoracoplasty, losing two. Meyer[274] in 1914 reported 16 lobectomies with eight deaths. Robinson[338] in 1917 reported a series of five lobectomies with one death. Four of the patients by operative dates and registration numbers were Mayo Clinic patients and Robinson, a Mayo Clinic surgeon. The fifth patient also his was from Massachusetts General Hospital. Robinson therefore must receive credit for introducing lobectomy for bronchiectasis to Minnesota. Harrington followed in 1931[158] and 1936.[159] Saurbrueh[355] in 1920 reported three single stage resections with three deaths. Lillienthal[248] in 1922 reported 21 cases with 12 deaths and seven recoveries. Graham[137] in 1923 reported three cases with two recoveries. Hedblom[167] from the Mayo Clinic reported on 48 cases using graded thoracoplasty in 18 with good results. Nissen[291] in 1931 operated upon a 12-year-old girl in stages mobilizing the upper lobe, pulling it out through the chest wall, amputating it later and following with thoracoplasty. Harrington[158] from Rochester in 1931 reported on 111 patients with 47 pulmonary abscess and chronic suppuration in 64 using thoracoplasty in 31 with good results and only three deaths, lobectomy in four with two deaths and partial resection on nine with four deaths. He[159] reported a right lower lobe resection by the tourniquet technique with recovery in 1936.

Cameron Haight[150] of Ann Arbor did the first successful pneumonectomy for bronchiectasis in the United States in 1932. Nissen[291] of Berlin in 1931 had done a two stage mass ligation of the hilum allowing the lung to slough on the eighth day. Sauerbruch[356] in 1923 in removing a very large ganglioneuroma had injured the blood supply of the lung which necrosed and sloughed, a thoracoplasty was done. The patient recovered. There was no bronchial fistula.

With improved technique and the use of individual ligation of the hilar structures and better understanding of the segmental anatomy of the lung the risks became less. Individual ligation of the hilar structures was used by H. Morrison Davies[76] of England in carcinoma of the lung in 1912. The Jackson[181] and Huber classification of the pulmonary segments and the anatomical work of Boyden[38] did much to develop this technique. Used by Churchill in 1931, by Blades and Kent[200] in 1940 and Overholt[301] in 1941, this became the method of choice and reduced the mortality.

The old warning of Robinson:[339] "Let no man dare to excise a lobe of the lung in a single stage" became obsolete and single stage resections became the rule. Chest suction postoperatively and later antibiotics reduced the mortality very drastically.

Our first attempts to control bronchiectasis began in 1928, when we explored the chest of a young girl with a severe right lower lobe putrid bronchiectasis of years standing with repeated

pulmonary hemorrhage. The plan was to mobilize the lower lobe, deliver and fix it in the posterior incision to be clamped and excised at a later date after adhesions had formed to wall off the pleural cavity. Unfortunately the lobe was so densely adherent to the diaphragm and pericardium that it could not be freed without tearing into the adjacent bronchiectatic abscesses. On December 7, 1928 the adherent lower lobe was exposed and a Graham Cautery drainage carried out. This was well tolerated; with external drainage the symptoms improved, but there was still considerable cough and expectoration. Bronchograms revealed additional involved areas. Additional cautery was done in 1929 and 1930, being very cautious not to do too much close to important structures. The patient improved considerably in spite of the daily routine of dressings. Bronchograms revealed only one segment still involved. She died of respiratory obstruction in 1931 with no residual bronchiectasis.

The second Graham cautery patient, a young man, was done at the University Hospital without incident. He died five days after the operation from hemorrhage from his wound. The next two who had pulmonary tuberculosis also were done with good results, becoming sputum negative and symptom-free. The first survived 20 years, dying from hypertensive disease, the other is still alive and working some 30 years later. A few more were done subsequently without mortality.

Our first one-stage surgical excision in the Twin Cities was done on a four-year-old boy at Minneapolis General Hospital[278] using a tourniquet ligation technique in 1937. He is in good health today. Postoperative empyema was frequent following this technique. Individual ligation soon replaced the tourniquet with fewer complications. We did a left total pneumonectomy[351] in 1937 on a 19-year-old girl who had had bronchiectasis since infancy. More than 20 sputum smears and three guinea pig innoculations had been negative for tuberculosis. The operation was long and difficult with over 1,000 cc of sputum being aspirated from the trachea by Dr. Knight during the procedure which withal was well tolerated. She died six weeks later from disseminated tuberculosis. The excised lung showed much tuberculous disease in spite of the negative findings. The early surgery was without the benefit of antibiotics and the first few without physician anesthesia.

We pioneered resection surgery in Northern Minnesota in 1938, doing a lobectomy for Nopeming Sanatorium[292] near Duluth and a pneumonectomy for Middle River Sanatorium in 1940. Later Jensen and Schmidt took over. Later in Duluth Dr. William Seybold[118] and Dr. John Kirklin[118] from the Mayo Clinic came up to do the work until Dr. Josiah Fuller,[118] a Rochester-trained thoracic surgeon, established practice in 1953.

With the development of intrathoracic surgery, it became necessary to devise equipment to evacuate fluid and air from the pleural space and to maintain expansion of the lung postoperatively. This led to our developing at the Minneapolis General Hospital a suction machine with controlled negative pressure with the suction maintained by a filter pump on a water faucet. Later at Glen Lake Sanatorium with the cooperation of the chief engineer, C. S. Sampson, the suction was provided by the vacuum line of the central heating system. Later the Stedman electric pump was incorporated into the machine, making a portable and compact apparatus. Dr. Robert Glover[132] in 1945, who had spent three months with us at Glen Lake while on his residency at the Mayo Foundation, modified this apparatus which later at the Clinic became known as the Glover suction.

Later at St. Mary's hospital, Minneapolis we became concerned by the occasional local failure of electrical power with the loss of suction or a broken connection or leaking tube between the patient and the machine. With the aid of Oliver Moe, a local instrument maker in 1951-52, we devised a safety valve interposed in the circuit to prevent loss of intrapleural negative pressure. This device, built on the principle of the Thiersch Flapper valve for empyema drainage or the valve used in the Momson escape lung for submarine rescue work, was simple and disposable. It was a check valve made of a small glass cylinder in which a six-inch length of thin penrose tubing was suspended with or without a Z-shaped wire frame to angulate the tubing. By experiment it was found that this check valve could hold a negative pressure of 30 cm. of water for as long as 12 hours with the vacuum pump turned off. We have used this device on all cases for more than 15 years very satisfactorily. Recently a commercial device of similar type has appeared on the market.

There was a considerable backlog of bronchiectasis built up over the years so that for a time after we started resection for this disease, we did a fair number of lobectomies for this condition. Up to the early fifties we saw a fairly steady volume of these cases, but after that it fell off rather steadily as the backlog was cleared up. The experience and technique gained in handling these cases stood us in good stead when resections for tuberculosis came into the picture. In later years in Minneapolis, Dr. N. K. Jensen, Dr. W. Robert Schmidt, Dr. Joseph Garamella, Dr. Frank Johnson, Dr. J. Grismer and Dr. Richard Larson in Minneapolis and Dr. Logan Leven, Dr. Coleman Connolly, Dr. Lyle Tongen and Dr. Sam Hunter in St. Paul did this type of work. With time, antibiotics, better treatment of infectious diseases and pneumonia, and better anesthesia for tonsillectomy, the incidence of this condition has dropped to a new low.

Pulmonary Abscess

Pulmonary abscess and pulmonary gangrene had been recognized as extremely serious conditions which before the days of chemotherapy carried the highest mortality of any disease of the chest with the exception of carcinoma. The differentiation of true pulmonary abscess and bronchiectatic abscess was not clear in the earlier recorded cases.

Politeau[316] and Dared in 1783 advised incision to the pleura and trocar-cannula insertion to the depth of the pus. Faye[316] in 1797 operated for adherent abscess punctured, opened, irrigated, and tamponed the cavity. Jaymes and Richerand[316]in 1813 also advised incision and drainage. Callisen[45] in 1815 advised puncture paracentesis and if pus was found, incision to the fluid area. Brichatan[316] in 1830 opened the area with caustic paste and incised the abscess. The patient lived nine months. Before the Minnesota State Medical Society, Dr. Christian Fenger[106] of Chicago in 1881 described open drainage of pulmonary cavities, quoting four cases successfully treated by open drainage, making counter drainage in one which proved to be an echinococcus cyst whose wall he removed by finger dissection. Murphy[283] in his Presidential address to the American Medical Association in 1898 mentions trocar drainage. Dr. C. H. Mayo[265] reported in 1898 on pneumonotomy for pulmonary abscess on three patients with two deaths and one recovery. Frankel in Germany in 1899 reports that 5% of "Flu" pneumonias ended in gangrene.

Emile Holman[176] in 1926 proved experimentally that pulmonary abscess could be produced by septic emboli. Smith[376] in 1927 produced pulmonary abscess by the intrabronchial injection of pus. This emphasizes the importance of the cough reflex in protecting the lung from aspirated material. Clinically the average abscess seen is the result of aspiration of material or foreign body in a submerged or unconscious patient rather than an embolic process for the usual embolus is a sterile clot rather than a septic one. Lambert[227] and Weeks in 1929 emphasized the role of the anaerobes in abscess formation. Neuhof and Tourof[288] in 1936 recommended the two-stage drainage of putrid abscess. Kent in 1947 advocated resection for treatment.

Many other isolated case reports may be found, but in spite of some favorable results Graham[137] in 1923 collected 48 cases with a 52% mortality. Wangensteen[418] described his graded cannula-cautery technique for drainage in 1937.

Pulmonary abscess is a complication of tonsillectomy under general anesthesia, aspirated foreign body, vomiting in an unconscious or obtunded patient, head injury and cerebrovascular accident, particularly in the patient with pyorrhea or other gum disease.

Bronchoscopic aspiration, removal of foreign body, dilatation of stricture aided materially. It was not until antibiotics particularly penicillin became available that real progress was made. Penicillin in large doses worked wonders and cured a large percentage of abscesses.

Abscesses which have not responded to rest, postural drainage, and bronchoscopic drainage should be surgically drained in one or two stages, depending on obliteration of the pleural cavity locally without waiting for the process to become chronic. If drained adequately early with removal of the dead tissue the surrounding lung tissue expands rapidly to obliterate the cavity. In the chronic stage the sclerotic wall is rigid and will not close leaving a chronic cavity with a bronchial fistula. With the advent of chemotherapy, particularly with penicillin, many acute abscesses clear rapidly, often completely. Less than 10% require drainage and the number of complications is reduced. Drainage in the chronic stage for control of hemorrhage might result in

months of dressings and plastic procedures.

With improvement in resection technique and intensive chemotherapy chronic abscesses may be resected instead of drained with low risk and short hospital stay. Our service at the Minneapolis General Hospital[278] from the mid-thirties produced a considerable number of abscesses successfully treated in standard manner by early drainage in one or two stages. If improvement was not rapid and progression occurred, resection was undertaken from mid-1938. With adequate antibiotic therapy few resections became necessary.

Bronchoscopy and Esophagoscopy

Bronchoscopy and esophagoscopy have played an increasingly important role in the diagnosis and treatment of intrathoracic disease. Bozzini[39] in 1807 examined the upper end of the esophagus. Horace Green[305] of New York in 1828 demonstrated an ulcer of the larynx with instruments. Voltolini[413] and Waldenburg[415] in 1860 devised an esophageal speculum. Waldenburg in 1868[415] devised an esophagoscope 8 cm. long using a mirror and inspected a pharyngeal diverticulum. Kussmaul[223] in 1868 did the first direct esophagoscopy using a 43 cm. Desormeaux urethrascope and saw a carcinoma of the esophagus. Von Hacker was the first to stress the value of direct vision. A. Kussmaul,[223] who apparently was the first to wash out the stomach in gastric dilatation, is reported to have attempted to look down the esophagus and stomach unsuccessfully in 1869. Trouve devised a polyscope using prisms and lenses in 1873. Mikulicz in 1881 used a tube with optical apparatus and later with larger tubes examined the stomach. A new instrument was devised by Storerk in 1881. Joseph O'Dwyer[305] developed his intubation tubes for laryngeal diphtheria in 1885. Killian in 1897 removed a bone by tracheotomy and tracheoscopy and did a bronchoscopy in 1898. Killian[305] in 1902 stated that direct esophagoscopy was the only reliable way of removing foreign bodies. Einhorn devised an esophagoscope with an auxiliary tube for the light, in 1902. Jackson in 1904 combined the tube of Killian with the light tube of Einhorn.

Foreign bodies likewise directed interest in this field in Minnesota. Dr. C. H. Mayo[263] in 1895 removed a lost O'Dwyer intubation tube through a tracheostomy. Again in 1896 he[263] reported removing a citron seed and a kernel of corn through a tracheostomy and three from the esophagus, a chicken bone through an esophageal incision, a prune stone from the lower esophagus and an oyster shell pushed into the stomach for removal. The next year, 1897, through a cervical esophagotomy incision[264] he removed a vest buckle which had been demonstrated by an Xray taken by Dr. J. Grosvenor Cross.

Dr. George Eitel[96] assisted by Dr. Dunsmoor in 1898, successfully removed a partial dental plate impacted in the esophagus for six years through a left esophagostomy incision.

Dr. Arnold Schwyzer[365] of St. Paul in 1903, using a Killian scope with a Casper panelectroscope brought from Europe, removed a foreign body through a tracheostomy wound for the first bronchoscopy in the Twin Cities. Primarily a general surgeon with wide interests, he possessed a keen mind and wide knowledge and added much in many fields to many meetings. In this field he did many foreign body extractions from the trachea and esophagus, using radium in the treatment of carcinoma, and drained mediastinal abscess. He also did the first cystoscopy in Minnesota in 1894.

Drs. Plondke and Schwyzer[365] of St. Paul in 1904 did a tracheostomy for foreign body, the patient coughing out the kernel of corn when the trachea was opened. Dr. William Lerche[242] came to St. Paul in 1905 from Austria where he was trained and for years was a leader in this type of work. He removed a tack from the bronchus in 1908, the first peroral procedure of this type in St. Paul, and listed 40 such procedures with mortality. He made many contributions over the years, including esophageal sounds, a loop for closing open safety pins, and improved esophagoscope, a calibrated Kohlman dilator for strictures, and later surgery for mediastinal abscess. Following him in St. Paul was Dr. D. Greth Gardner[123] who became his associate in 1920. Also in 1920 Dr. Charles Connor[62] came to St. Paul after training with Chevalier Jackson, working at Miller, Children's and the University Hospitals. Dr. John J. Hochfelzer, Austria-born and Vienna-trained, entered practice in St. Paul in 1924 followed in 1930 by Dr. Jerome Hilger.[172] in 1932 by Dr. N. Logan Leven[239] and in 1946 by Dr. Coleman Connolly.

Dr. Frank Todd[395] in Minneapolis reported removing a peanut in 1909 and a tack from the

right upper bronchus using a Jackson scope in 1904. Dr. J. D. Lewis did occasional foreign body cases at the Minneapolis General Hospital. Rizer[331] who had done bronchoscopy and esophagoscopy for Sippy of Chicago came to Minneapolis in 1915 where he continued to do these procedures in his own practice and at the University. He also used the string guide in esophageal dilatation. Kenneth Phelps[311] came to Minneapolis from Johns Hopkins in 1919 and from that time on was the dean of the profession in the city, doing most of that work in private practice and at the University and Minneapolis General Hospitals. Horace Newhart[311] and his associate, Walter Camp, performed these procedures using the Killian instruments in 1920. Virgil Schwartz[364] after finishing his residency in Otolaryngology at the University and General Hospital spent a year in Vienna with Hasslinger, returning to the City to private practice in 1923 and the service at the General, using the Hasslinger instruments and later the Jackson type. All of the previous men were nose and throat specialists. Arthur Kerkhof[201] an internist upon completion of his residency at the General Hospital in 1932, was sent by Dr. George Fahr to Vienna for a year of study with Hasslinger, returning to private practice as an internist doing endoscopic work as well.

Lawrence R. Boies[36] began practice in Minneapolis in 1931 in Otolaryngology and Bronchoscopy, continuing for a number of years until he became head of the department at the University. J. Bain Carey,[46] an internist, interested in gastroenterology, after a period of training with Schindler returned to do gastroscopy with the Schindler flexible gastroscope in private practice and at the University Hospital. Soon, as the demand for diagnostic endoscopy increased as chest conditions were more carefully studied, a number of well-trained and grounded endoscopists appeared: Priest, Holmberg, Richardson, Smith, Glaser and others.

With the interest previously shown by the surgeons at the Mayo Clinic, it is not surprising that the medical side also became involved. Henry S. Plummer[312,315] came to Rochester in 1901 and immediately became interested in the esophagus and its troubles and continued this interest until 1923 when he turned the work over to Porter P. Vinson.[312] His contributions included treatment of stricture by dilators and the Albee string saw, dilatation over a string guide (originated by Mixter), retrograde dilatation, an improvement of the Russell[345] hydrostatic dilator, removal of foreign bodies, recognition of carcinoma and biopsy of tumor. He described the Plummer-Vinson syndrome[315] in a paper in 1914 written and presented, but not published. He was a mechanical genius and in his own shop made many of his own instruments for special problems. He is known to have traveled to St. Paul to observe Dr. Lerche at work. Eccentric in many ways but a true genius along many lines, he was responsible for a great number of mechanical improvements about the Mayo Clinic and its buildings.

Porter P. Vinson[312] came to the Clinic in 1917 joining Plummer and later taking over the endoscopic work as well as internal medicine. He was joined by Herman Moersch[312] in 1924 and later by Arthur Olsen, Herbert Schmidt, and others. From the beginning endoscopy at the Clinic has always been in the medical chest department.

The first endoscopist in Duluth was N. H. Gillespie[91] who brought endoscopes from Vienna in 1908. Later beginning in 1910 Tildcrquist[91] began this work and continued for years, being joined in 1926 by Anderson Hilding[91] who continues to date. Paul Boman from the Duluth Clinic began this work in 1922. Keith Fawcett of the Duluth Clinic introduced the work to the Nopeming Sanatorium in 1937 where it was taken over in 1939 by Robert Davies and in 1946 by Reno Backus. Herbert Carlson[49] at the Minnesota State Sanatorium at Ah-Gwah-Ching did bronchoscopies from 1937-39. C. L. Oppegaard[68] began in 1940 at Crookston.

C. L. Chambers[284] of Bismarck, North Dakota, was doing bronchoscopies in 1924 and C. O. Robinson, esophagoscopies in 1926. McCannel,[284] a nose and throat man, and Paul Breslich[284] an internist, pioneered endoscopy in Minot. Nelson Youngs[435] of Grand Forks has been active in this field since 1934. George A. Dodds,[85] 1937-39, and later George Loeb[250] did endoscopic work at the State Sanatorium at San Haven.

John Gregg, Sr.[65] of Sioux Falls, South Dakota, reported removing a kernel of corn from the bronchus in 1922, the first in the state. Paul Bunker[44] of Aberdeen removed a foreign body in 1930, the second in the state. He received

the Chevalier Jackson award of the American Bronchoesophageal Association in April, 1966, the sixth individual to be so honored.

Tuberculosis

Tuberculosis has posed a threat to the human race since the beginning of recorded history. It is properly called "Captain of the Men of Death." Almost every type of treatment has been tried in this disease including the "Royal Touch" for scrofula. William of Orange, disbelieving in its value but for political reasons continuing it, added the following: "and God give you better health and better sense."

Tuberculosis in Minnesota and the Dakotas

The early explorers and settlers of Minnesota came from Europe where Tuberculosis was a common disease. The Indians were apparently free of this until contaminated by the white man. Williamson,[425] a missionary physician at Lac qui Parle in western Minnesota from 1835 to 1846, stated that half of the Indians over the age of ten who died of disease had tuberculosis. More settlers arrived in the fifties and brought disease with them. Commercial interests[279] to encourage more settlers advertised that the "elixir in the air" of Minnesota cured consumption, bronchitis and other diseases of the chest. Health seekers, ever in the hope of a magic cure, came in large numbers, some to recover, others to succumb, and to spread their disease to others. Among the famous health seekers to visit Minnesota was Henry David Thoreau[394] from Massachusetts who in 1861 took a trip up the Minnesota river to Redwood Falls. Another famous health seeker was Dr. Edward Livingston Trudeau,[394] one of the pioneers in the treatment of tuberculosis. He arrived in St. Paul in the fall of 1873 febrile, but he walked about and went duck shooting. He spent the winter here, returning to New York in May of 1874.

The State Legislature of 1903 authorized the construction[284] of a State Sanatorium near Walker on Leech Lake which was opened in 1907. The private sanatorium of H. L. Taylor was opened in 1903 at Pokegama in Pine County and the same year a tuberculosis unit was started at Luther Hospital, St. Paul. Later it was transferred to Ancker Hospital. The sanatorium law of 1913 provided for construction of 14 county and district sanatoria for the treatment of tuberculosis. In line with the medical thinking of the day, all of these were placed in isolated locations or well away from other established medical or surgical facilities with the exception of the Pavilion at Ancker Hospital. This proved to be a very serious handicap when surgery came into the treatment picture and a great inconvenience to the visiting and consultating staff. Surgical facilities were eventually provided at Glen Lake, Nopeming, Mineral Springs, Sunny Rest, and the State Sanatoriums, but operated under many handicaps. The Pavilion at Ancker Hospital was of course part of a general hospital.

The state of Minnesota from 1915 to 1925 was averaging at least 4,000 cases of Tuberculosis per year on an increasing scale. There was a dire need for facilities for isolation and treatment to meet this challenge. The institutions built under the sanatorium law are here listed with maximum[284] capacity.

		Beds[284]	
1905	Pokegama, Pine City, Private Closed 1944	42	
1907	Thomas Hospital, Minneapolis Closed 1930	20	
1907	Hopewell Cottage, Minneapolis Closed 1924	130	
1907	Minnesota State Sanatorium, Walker Closed 1962	240 115	Whites Indians
1912	Nopeming, St. Louis County near Duluth	300	
1913	Otter Tail, Battle Lake	48	
1914	Ancker Hospital, St. Paul	188	
1915	Mineral Springs, Cannon Falls	100	
1916	Sunny Rest, Crookston	60	
	Lake Julia, Puposky	52	
	Glen Lake, Hennepin County, Minneapolis	680	
	Sand Beach, Lake Park	42	
1917	Buena Vista, Wabasha	30	
	Southwestern Minnesota, Worthington	45	
	Riverside, Granite Falls	48	
1918	Oakland Park, Thief River Falls	65	
	Fair Oaks Lodge, Wadena	36	

As of July, 1968, all of these have been closed except Glen Lake which is now the State Sanatorium but has under fifty Tuberculous patients, Ramsey County Hospital (Ancker), Nopeming now with a much reduced capacity, and Mineral Springs.

The early sanatoria had little to offer in the way of treatment except prolonged bed rest which might even be continued for years. Under such a program a patient with minimal tuberculosis had at least a 90% chance of recovery, one with moderately advanced disease about 60% chance, while

the far advanced case only 10%, unless some other help could be added. The first procedure available was artificial pneumothorax. It was primarily a bedside type of treatment with no patient too old or too young or too ill.

Pneumothorax

The Hippocratic school[216] is reported to have injected air into the pleural cavity to facilitate drainage in empyema patients. James Carson[52] in 1822 following numerous experiments on a variety of animals reported that one lung could be safely collapsed by injection of air into the pleural cavity and suggested that it be used in treatment of tuberculosis. Daniel McRuer[269] of Bangor, Maine, in 1835 made the suggestion that puncture of the chest to admit air to suspend the function of the lung might be of value in phthisis. Potain[318] in France in 1880 suggested aspirating a pleural effusion in tuberculosis and replacing with air, and in 1884 carried out this operation. Carlo Forlanini[109] from the University of Pavia in Italy in 1888 carried out the same procedure and in 1892 established the first primary therapeutic pneumothorax. R. W. Parker of London, discussing a paper "Hemoptysis treated by artificial pneumothorax" by W. Cayley, quoted him as recommending "the injection of filtered and carbolized air into the pleura such as he had advised in the treatment of certain kinds of empyema." John B. Murphy,[283] of Chicago in 1895, apparently in ignorance of Forlanini's previous work, established pneumothorax for the treatment of pulmonary tuberculosis and in his presidential address to the American Medical Association in Denver in 1898 reported upon its use and other procedures for tuberculosis. Alarmed at the enthusiastic reception which this procedure received and fearing that he would become known as a medical man rather than as a surgeon, he turned the treatment over to his associate, Dr. August F. Lemke.[235] He followed up the treatment aggressively and by 1901 had treated 350 cases whereas Forlanini by 1911 had only 86. He also must be credited with performing the first alternating bilateral pneumothorax. The death of Lemke certainly delayed the spread of pneumothorax treatment in this country for several years while European physicians continued to develop it.

A publication of Adams in 1887 cited a case of pulmonary hemorrhage which was controlled by the occurrence of a spontaneous pneumothorax. Walker Schell[358] of Indiana in 1898 reported injecting 1,400 cc of nitrogen into a pleural cavity to stop pulmonary hemorrhage in tuberculosis. H. P. Loomis[252] in 1900 reported 18 cases of which eight were started to arrest hemorrhage.

Xray in 1895 added much to the knowledge of lung disease and control of pneumothorax treatment. Christian Saugman[349] of Denmark added the water manometer to the pneumothorax machine in 1907, greatly increasing the safety of the procedure.

When Lemke died, interest in the treatment in this country decreased for a number of years and few published articles appeared in the American literature. About 1912 following the appearance of several articles by Mary Lapham[231] of North Carolina, and Pratt, Robinson, Floyd and Balboni[16] of Boston describing their experiences, Samuel Robinson[335] and Cleveland Floyd developed a compact pneumothorax apparatus with a water manometer which became the model for use throughout the country. Nitrogen was used for injection in controlled amounts with controlled pressure. In 1912, Cleveland Floyd[284] of Boston established the orginal pneumothorax on Edward L. Trudeau, reducing his fever and rendering his sputum negative. Gerald B. Webb[424] of Colorado Springs brought pneumothorax to the Rocky Mountain region in 1912 and subsequently with his associates, by analysis of the residual gas in the pleural cavity, demonstrated that the composition was approximately the same whether nitrogen or air was originally injected. This work resulted in the use of filtered air and the abandonment of nitrogen. By the twenties pneumothorax was in use in most of the larger sanatoria of the country, as the first surgical procedure to use in the patient who did not improve under bedrest or who developed serious bleeding.

H. Longstreet Taylor[393] of St. Paul in 1899 performed the first active procedure directed against pulmonary tuberculosis in the state by establishing the first artificial pneumothorax. He injected two quarts of nitrogen into the pleural cavity of a young girl at Bethesda Hospital. The patient improved for a month or so and then the symptoms returned. Unfortunately the treatment was not repeated. He likewise did the first pneumothorax at Pokegama in 1921.

The first therapeutic pneumothorax was established at Glen Lake Sanatorium in 1916,[131] more

than four years before the first x-ray equipment was installed. It was given probably by Dr. Fred W. Wittich[131] who was consultant to the Glen Lake Sanatorium at that time. Dr. Wittich had in 1914 with C. H. Vrooman[414] of the Provincial Sanatorium at Kamloops, British Columbia, Canada, published a paper "Apparatus for Producing Artificial Pneumothorax."

Dan Wheeler[292] of Nopeming Sanatorium near Duluth established the first pneumothorax at the Head of the Lakes in 1924. We have no records of such treatment at Ah-Gwah-Ching, the State Sanatorium before 1937.

To Lemke must go the credit for performing the first alternate bilateral pneumothorax. Fagiuoli and Ascoli[103] in 1912 induced the first simultaneous bilateral collapse and continued it, but it did not become a popular treatment. Everett K. Geer[125] of St. Paul is credited with the first simultaneous collapse in the state of Minnesota in 1922 publishing a report in *Minnesota Medicine* in 1923. Glen Lake's first bilateral collapse was started by Dr. Harold Boquist[131] in 1924. An accidental pneumothorax occurred at the time the second side was established, but no dyspnoea occurred as there was considerable reserve breathing space on the opposite side at the time. The patient is in good condition and symptom-free to this date, 44 years later. Dr. P. M. Mattill[203] and I reported on 108 patients so treated by the staff of Glen Lake Sanatorium in 1927. Alexander Josewicz[234] must be credited with the first diagnostic pneumothorax territory which was in Minneapolis.

The value of pneumothorax treatment has been amply demonstrated by the extent of its use (up to 50% of patients) in some large institutions and the thousands of patients who recovered from tuberculosis because of it. No patient was too old or too young or too ill to be tried on this bedside procedure. That there were disadvantages and complications must be admitted, but many of them were avoided by careful management. The worst form of mishandling was the indefinite continuation of unsatisfactory collapse and trying to "stretch" limiting adhesions.

At one time ambulatory pneumothorax enjoyed a brief period of popularity. It was used by force of circumstances in Chicago where a huge load of active cases of Tuberculosis accumulated with all available hospital beds occupied. The health authorities hoped that by pneumothorax collapse, some cavities might be closed and sputum rendered negative, thus reducing the danger of dissemination of the disease about the City. Jay A. Myers was the only physician in the local area to use it to any extent.

An illustration of the extent of the prevalence of pneumothorax among discharged patients comes from my own office. When in World War II, I was making arrangements to transfer my patients to other physicians as I prepared to enter service, my secretary found that we had 118 working patients with pneumothorax, with 18 of them bilateral.

Intrapleural Pneumonolysis

The success of the pneumothorax treatment of tuberculosis was dependent upon finding sufficient free pleural space to permit collapse of the involved areas and closure of the cavity. Limiting adhesions frequently defeated all efforts to control the disease. Hans C. Jacobaeus[182,183] of Stockholm, Sweden, in an attempt to remedy the situation conceived the idea of sectioning the limiting adhesions and devised an endoscope for visualizing them in 1913 and subsequently severed some with galvanocautery. Jacobson in 1914 and also Heuve[171] cut some under fluoroscopic guidance. Jacobaeus visited the United States in 1921, giving lectures in various cities including Minneapolis, and on November 14, 1921, delivered one[287] which I attended at the Mayo Clinic. Glen Lake Sanatorium purchased the proper instruments soon after that, permitting Frank Jennings[131] to undertake the procedure first in 1923. He was able to cut a few small strings but was unable to close the cavity held open by a large thick adhesion totally unsuitable for section. Gradually under continued pneumothorax this cavity closed, the patient obtaining a good result which has persisted to date. The instruments then remained unused on the operating room instrument shelves, as many very expensive special instruments do, until July 14, 1927 when I explored a patient's chest but was unable to sever all adhesions. Her cavity was later closed following an open thoracotomy with manual compression of the cavity-bearing adhesion without severing it. I continued to do this type of surgery at Glen Lake over the years and introduced it to Mineral Springs Sanatorium, Wabasha, Sunny Rest in Crookston, Pokegama, Nopeming and Walker in the late thirties. Herb Carlson[49] had

previously done several cases there between 1937-39.

Complications were: subcutaneous emphysema, occasionally with loss of collapse, bleeding from the parietal stump of the severed adhesion, pleural effusion or empyema, usually tuberculous. Empyema was the most frequent, possibly reaching 10%, depending upon how drastic the surgeon became in attempting to extend the indications.

The results from adhesion cutting depended upon successful section of most, not all, adhesions holding the cavity open; in other words, converting an unsatisfactory pneumothorax into a satisfactory one, if no complications ensued. With the advent of specific drugs the use of pneumothorax dropped rapidly and likewise the need for pneumonolysis.

Extrapleural Pneumonolysis and Pneumothorax

The use of extrapleural stripping came early into the field of thoracic surgery. Block[33] in 1883 performed a bilateral extrapleural resection of apical disease upon his cousin. When the patient died soon after the operation and the disease proved to be non-tuberculous, he took his own life. Tuffier[397] of Paris in 1891 successfully performed an apical stripping and then resected a tuberculous nodule from the lung. The marvel is not that he was able to do it, but how he was able to diagnose the lesion in the first place for Rontgen did not discover Xray until four years later. Schlange[360] in 1907 resected six centimeters of the anterior third rib, did an extrapleural pneumonolysis to control pulmonary hemorrhage and packed the space created with iodoform gauze. Tuffier[398] in 1910 did an extrapleural stripping and filled the space with a free fat graft. Later in 1913, Baer[13] used paraffin; Wilms, bone fragments; and Guilder and Kroh[219] and later Harvey, an inflated rubber bag. Shivers[370] of Colorado Springs and Archibald of Montreal used the pectoral muscles. Tuffier[398] before using the "fat pack" had once filled the space with air as an extrapleural pneumothorax, while Jennings[184] had done the same, leaving an external fistula to the skin. Bull, Shivers,[371] Schreiber[363] and Stocklin used apicolysis in association with thoracoplasty. Wilms[427] and Sauerbruch[353,354] also used pneumonolysis with thoracoplasty. Jessen[187] and Unverricht[402] did an extrapleural stripping over the attachment of a large adhesion in pneumothorax.

To my knowledge no one in this area performed extrapleural pneumonolysis until at Glen Lake we carried out the first "paraffin pack"[131] in 1934. This pack is still in place and has caused no trouble. Over the years we carried out more than 58 such operations, six of them bilateral, with no complications for five years in patients with obliterated pleural space. We then began to see complications such as persistent effusion about the paraffin, migration of the wax, perforation of the lung with expectoration of paraffin strings and infection of the space, confirming Ralph Matson's[261] statement that "they worked very well for five years, then blew up." Now although many of these patients survived, only about a half-dozen still carry their packs, the others having been removed because of complications.

In 1938 instead of using paraffin in the extrapleural space, we began to use pneumothorax to maintain the collapse and continued refills as in ordinary pneumothorax. G. A. Hedberg[292] who had been working with us for some time, did his first extrapleural pneumothorax in 1939 at Nopeming Sanatorium. The use of air filling for the extrapleural space eliminated many of the complications of this procedure. This type of collapse gave some chance of discontinuation later. The presence of some free pleural space did not contraindicate its use as it did in true extrapleural procedures, but permitted the extrapleural stripping of a large limiting adhesion and the conversion of a previously unsatisfactory pneumothorax to a satisfactory one. Many of these were filled with mineral oil and continued as an extrapleural oleothorax. The results were quite satisfactory. This procedure offered a relatively safe means of bilateral collapse without great reduction in vital capacity.

Phrenic Nerve Surgery

Surgery upon the phrenic nerve was first suggested by Steurtz[386] in 1911 for treatment of a left lower lobe bronchiectasis. Harrington, in discussion of a presentation on phrenic nerve surgery by Howard K. Gray[142] before the Mayo Clinic staff, stated Bardenheuer[18] did the first such operation in 1912. Sauerbruch[355] in 1913 performed phrenic interruption and reported five cases with good results. Gradually use of the technique spread, at first by evulsion of the trunk (phrenic

exercsis) from a cervical incision, later by cutting the main trunk, later with interruption of accessory branches which occur in about 30% of patients, both of these giving a permanent paralysis of the diaphragm. Subsequently the main trunk and branches were crushed (phrenemphraxis) to give a temporary paralysis which lasted about six months, though some were permanent depending upon the length and the severity of the crush. The physicians in this area never became this enthusiastic about it, realizing the importance of the diaphragm in patients with bilateral disease where the loss of its motion might preclude the later use of other necessary surgery because of reduced respiratory reserve induced by it. The first such operation at Glen Lake was done by A. A. Law[131] in 1924. Only seven such operations were done to 1927 though more were done subsequently, most of the temporary variety, after I took over the surgery at the Sanatorium. Later I started this type of collapse at Mineral Springs and Sunny Rest. Carlson did a[49] number of phrenic operations at the State Sanatorium during his term there, 1937-39. Chapman[53] and Gillespie carried out the operation at Nopeming. Law also did some at the University Hospital. The surgeons at the Mayo Clinic used the procedure not only for tuberculosis but also for bronchiectasis and with other surgery in diaphragmatic hernia. Later it became an aid in space obliteration following lobectomy and pneumonectomy.

Ligation of Pulmonary Artery

Kuttner[224] in 1878 was the first to follow the changes in dogs after ligation of the pulmonary artery. O. Bruns and Sauerbruch[43] in 1911 repeated the experiments and at the end of three months noted marked fibrosis of the lungs. K. Kawamura[196,197] in 1913 again repeated the experiments on rabbits and dogs with similar results. Willy Meyer in 1913 tried it in bronchiectasis clinically with partial success. Sauerbruch[352] used it in 14 cases of bronchiectasis with some success and noted extensive fibrosis and retraction.

Karl Schlaepfer[361] of Baltimore in 1923-24 repeated the studies and noted intense fibrosis and retraction in shorter time than the pneumothorax or thoracoplasty. He mentions obstruction of the bronchus by fascia as suggested by Halstad and Crowe. A few cases were done by Sauerbruch, Kuttner and Willy Meyer. There are few other reports of its use except occasionally to control hemorrhage. I know of no local use of this procedure.

Dr. H. Morriston Davies[76] in 1913 ligated the pulmonary artery in an attempt to control pulmonary tuberculosis.

Scalenectomy and Intercostal Neurectomy

Scalenectomy

Sections of the insertions of the scalene muscles in the neck were studied experimentally by Kochs, Els[215] and Junkersdorf in 1930 on monkeys and they proposed its use to relax the upward support of these muscles on the first and second rib. Gale and Middleton[121] independently made the same suggestion. John Alexander[5] of Ann Arbor carried out a few operations but the effect on clinical tuberculosis cases was not striking so it was soon forgotten. The procedure is automatically carried out when the first and second ribs are resected in thoracoplasty.

Intercostal Neurectomy

Warstat[423] of Konigsberg experimentally avulsed the intercostal nerves in rabbits and dogs and interrupted the phrenic nerve. Respiratory function ceased on the side as the chest wall fell into cadaveric position. Studies subsequent to intravenous injection of tubercle bacilli showed a few noncaseous tubercules on the operated side but many and larger lesions opposite. Later two patients were operated upon and improvement noted.

Schepelmann[359] experimenting on rabbits found that considerable immobilization of the side occurred but did not recommend it for humans. Hug[177] using dogs noted the same effects. Friederick[114] in 1913 carried out the operation on a human but was dissatisfied with the result obtained. Alexander in 1920 carried out the procedure on animals in conjunction with phrenic nerve interruption and was impressed by the amount of immobilization and flattening of the chest wall. Leota and Cimino[237] produced the same effects by injecting the intercostal nerves with alcohol. Alexander[5] first used the procedure on patients in 1927 and with Strieder[388] reported its use in 20 patients unsuitable for thoracoplasty because of very active disease and felt there was distinct benefit. It was never adopted very enthusiastically and was soon forgotten. I find only five records of its use as an independent procedure in the Glen Lake operative records.

Thoracoplasty

The term "thoracoplasty" means a plastic opera-

tion on the chest wall and may include anything from removal of a rib or two to drain an empyema to the most radical Schede operation with removal of extensive portions of the thoracic wall including rib, intercostal muscles and parietal pleura. As used for many years in the treatment of chronic empyema to obliterate pleural space, the lung was fixed and bound down, the pleural layers thickened and the mediastinum stabilized leaving the lung with very little function. Such operations as the Estlaender,[102] Wagner-Quenu and Schede[357] were used and fairly well tolerated.

The problem in tuberculosis was much different. The lung itself was diseased, the pleural layers though fused were not greatly thickened, the mediastinum was not fixed or stabilized. The extensive rib resections of the early days resulted in chest wall and mediastinal flutter with a mortality of at least 30%.

Thoracoplasty, for years the last resort in the treatment of pulmonary tuberculosis, developed from surgical attempts to obliterate the pleural pockets in chronic empyema. De Cerenville[78] in 1885 is credited with first using it in the treatment of tuberculosis, reporting four cases done for apical disease, resecting three and a half centimeters of ribs—two and three anteriorly, and in two draining cavities. Quincke[332] in 1888 carried out similar operations. Carl Spengler[380] in 1890 through a periscapular incision resected larger segments in patients with pleural effusion and used the term "extrapleural thoracoplasty." Boiffin[37] in 1894 resected segments of ribs at their angles in treating empyema. Julien Gourdet [136] in a thesis published in 1895 reported the results of his studies in which he found that the best collapse was obtained from resections at the angles of the ribs. Turban[399,400] in 1896 resected rib four to six and six months later seven to nine for tuberculosis. Garre and Quincke[322] in 1901-03 carried out thoracoplasty, supplementing it with extrapleural pneumonolysis. Bier[26] and Landerer also did thoracoplasty at this time. Friederick in 1907, at the instigation of Brauer who recognized the need for more collapse, resected larger segments (10-25 cm.) of ribs two to nine in one stage. The patient survived and was improved some 14 months later. The operation was done through a U-shaped (Schede) type of incision under light, local anesthesia and in a very rapid manner. There was terrific shock. Chest wall and mediastinal flutter followed. Brauer later reported that three of seven died and Friederick had four of eight fatalities. Friederick[16] later removed the first rib also. By 1911 there was a report of eight deaths in 29 cases (29.6%).

Sauerbruch[352] in 1909 carried out his paravertebral thoracoplasty and by 1911 had divided the surgery into two stages. Wilms[426] in 1911 demonstrated the value of the experimental work of Gourdet,[136] Eden[334] and Robinson with columnar resection. Later he used a parasternal incision to resect more rib. Brauer and Spengler[41] in 1913 carried out their subscapular paravertebral thoracoplasty. Brauer later worked out an anterior incision following Becker's suggestion.

Edward Archibald[12] of Montreal has for years been credited with carrying out the first thoracoplasty on this continent in 1917. This is probably true if one considers a thoracoplasty of the Wilms-Sauerbruch type. However, Leonard Freeman[113] of Denver, Colorado, in 1909 reported two patients upon whom he had operated in 1901 and 1902, resecting segments of ribs two and three anteriorly and then applying strong compression over the resected area with a truss-like arrangement to produce a marked depression. One patient, a 19-year-old boy from Denver National Jewish Hospital had a hemorrhagic phthisis with quite a large cavity below the left clavicle. He had had a spontaneous pneumothorax and empyema some months before and had had an extensive Estlander operation done without affecting the cavity, although two-thirds of the lung was compressed. He was raising several ounces of sputum, was emaciated and not improving. Five months after the operation he was improved and the sputum almost gone. Eight years later it had not returned.

The second patient treated in similar manner with resection of three-inch segments of the second and third ribs anteriorly and truss compression likewise obtained a good result with cavity closure and no recurrence seven years later. The remarkable thing about this result with very localized anterior compression lies in the fact that most tuberculous cavities lie in the apical posterior segments of the upper lobe rather than anteriorly. The operation which Dr. Freeman did was the same as DeCerenville's[78] thoracoplasty of 1885 with compression added. Later in May of 1920, Freeman performed[113] two thoracoplasties of a modified Sauerbruch type, ribs one to nine

in one stage.

Shortle and Geckler[371] in 1922 reported four cases of thoracoplasty done in 1920 although neither of the authors was a surgeon. Shortle had been an assistant to Karl Spengler during the winter of 1907-8. Geckler had been an assistant to Ludolph Brauer at Marburg when he suggested to Friederick the operation later modified by Sauerbruch. The first two cases in May, 1920, were done by Leonard Freeman[113] of Denver in Albuquerque for Shortle and both survived. The other two were done by Cornish and both died. I well remember at Glockner Hospital in Colorado Springs in 1924-5 watching Freeman doing a thoracoplasty on one of our patients from Cragmoor Sanatorium and treating the patient for deep shock which developed when at the conclusion of an upper stage thoracoplasty he very forcibly manually compressed the deribbed chest wall. John Alexander's[3] book "Surgery of Pulmonary Tuberculosis" published in 1925 while he was on the flat of his back in bed with multiple tuberculous lesions and before he had ever done a thoracoplasty became the standard text and reference book on treatment of tuberculosis. Up to 1918 less than 100 thoracoplasties were recorded.

Carl Hedblom[284] of the Mayo Clinic is credited with doing the first thoracoplasty for tuberculosis in Minnesota and the surrounding territory in 1919. E. P. Quain [321] of Bismarck, North Dakota, in 1920 did a multiple rib resection (six ribs) on a seven year old girl. This was for chronic empyema and not for tuberculosis. Arthur A. Law did the first such operation in the Twin Cities at Glen Lake Sanatorium[131] on January 22, 1922 on a 64-year-old man who survived for over 14 years.

Law was a superb surgeon, a fascinating teacher, interested in everything new and like many of the surgeons of his day a speedy operator. Speed was then considered a very important factor in early surgery for tuberculosis and in this field there was no one better fitted than Dr. Law. I have assisted him in an upper stage thoracoplasty, five ribs—complete from incision to the last stitch of closure in eleven minutes and lower stage six ribs in nine minutes. Shock was a constant aftermath and blood loss not a small factor. Later after we had taken over and chose to do the surgery under local anesthesia time was less important, taking an hour or hour and a half if necessary. Shock was rare, blood loss reduced, and a cleaner and better operation performed. Over a period of time our average blood loss at surgery plus the first two days drainage on the dressings was: upper posterior stage five ribs, 450 cc.; intermediate posterior, 290 cc.; lower posterior, 195 cc.; and anterolateral four ribs, 250 cc. Law continued this work until 1927 when he resigned because of ill health, turning the surgery over to this author who carried on to 1940 when Victor K. Funk[120] and Leonard M. Larson took over.

Stanley R. Maxeiner[262] of Minneapolis did his first thoracoplasty in May, 1924, at Parkview Sanatorium in that city. All of the old records before 1933 for Ancker Hospital, St. Paul, and all records from Pokegama Sanatorium at Pine City have been destroyed so we are a little uncertain as to exact dates from these two institutions. As near as can be ascertained L. E. Daugherty[75] of St. Paul performed his first thoracoplasty for tuberculosis in 1924 at Ancker Hospital and at Pokegama in 1925. Unconfirmed rumor has it that in the early days, Arthur Colvin[61] did a couple of extensive one stage thoracoplasties with fatal results convincing him it was a bad operation. Daugherty was followed by D. Greth Gardner who carried on in chest surgery as well as bronchoscopy for many years until Coleman Connolly, Logan Leven, Lyle Tongen, Gernard G. Lannin, and Sam Hunter entered the field.

T. O. Young and Dan Wheeler[434] carried out the first thoracoplasty at the Head of the Lakes at St. Luke's Hospital in 1925. In 1926 T. L. Chapman[53] and M. G. Gillespie did thoracoplasties for Nopeming at St. Mary's Hospital, Duluth. G. A. Hedberg of Nopeming reports doing thoracoplasty on 20 patients at St. Mary's in Duluth in 1937-38, and the first at Nopeming Sanatorium[292] in 1938, upon completion of operating facilities at that Institution. Law did a number of such cases in the early days at the University of Minnesota Hospital followed by Wangensteen, Varco and Herbert Carlson and others of the staff. While on the staff of the Minnesota State Sanatorium at Ah-Gwah-Ching, Carlson[49] carried out 37 stages of thoracoplasty, 1937-39. The first such operation at Crookston, Minnesota, was done by this author at Bethesda Hospital in Crookston for Sunny Rest Sanatorium in 1929. A few others followed until late in 1930 when M. O. Oppegaard[297] assumed the surgery.

Thoracoplasty in North Dakota was initiated in 1920 by A. P. Quain[321] of Bismarck for a nontuberculous chronic empyema on a seven-year-old girl. The early patients with tuberculosis from the State Sanatorium at San Haven near Dunseith were sent to the Mayo Clinic. Angus Cameron, Sr., of Minot[85] in 1935 operated upon two patients. When G. Alfred Dodds[85] took over as superintendent in 1937 he also took over the surgery for the Institution. He had been trained in tuberculosis at Glen Lake Sanatorium and soon instituted an intensive collapse therapy program with up to 71% of the patients under some such treatment. He did over 52,000 pneumothorax refills and did over 420 thoracoplasty stages under local anesthesia with 0.75% mortality. Later in private practice at first in Valley City and then with the Fargo Clinic, Dodds continued to do chest surgery and became the first in North Dakota to be certified by the Board of Thoracic Surgery. Later Fritzell of Grand Forks Clinic, Grant Tolsted of Bismarck and Angus Cameron, Jr., of Minot came into the field.

Cedric Northrup succeeded Dodds in 1939 and was soon joined by William Walbank[416] who was surgically trained and took over the surgical program until 1950. George Loeb[250] joined the staff in 1944 working with Walbank until he left for Toledo in 1950. The surgical program from 1944 to 1958 was very active. The first pulmonary resection for tuberculosis from the Sanatorium was sent down to St. Mary's[351] to us for a pneumonectomy in the fall of 1947. The patient was a Public Health nurse, who is well today. Subsequently with the introduction of adequate antituberculosis chemotherapy, all the major resections up to 1964 were referred to St. Mary's Hospital, Minneapolis.

South Dakota with its smaller population and no large cities naturally presented few opportunities for special work. Very little chest surgery was done until the last 10 years. Godfrey Cottam[65] of Sioux Falls did the first thoracoplasty in 1933 on a patient from the State Sanatorium at Custer. This arrangement continued for a time when fear of tuberculosis in a general hospital ended the transfers from Custer and the State Indian Sanatorium. The patients then for several years were sent to this author at St. Mary's Hospital, Minneapolis, or Glen Lake Sanatorium for surgery. Later the Indians were sent to the North Dakota State Sanatorium for surgery from which many Indians were transferred to St. Mary's, Minneapolis, for resectional surgery. Within the past ten years several surgeons qualified in chest work have located in the state.

Many modifications were developed until eventually the Wilms-Sauerbruch-Brauer technique became the most frequent type in vogue. Stage operations certainly reduced mortality. Better technique, better anesthesia, fitting the operations to the patient's condition and respiratory reserve and flexibility of the chest wall all contributed to the safety of surgery. Though still a last resort the indications for surgery were extended to include older and younger patients, to those with contralateral active but not progressive disease, cardiac lesions, and contralateral collapse by pneumothorax, phrenic, pneumonolysis and later even thoracoplasty. A dangerous operation became a very safe one. We reported in 1934 a consecutive series of 208 operations with no mortality from any cause within two months of operation, finally breaking the series when an accidental pneumothorax on the contralateral side followed a postoperative refill. Later Drs. Funk and Larson carried out a consecutive series of 752 operations without any mortality under eight weeks.[120] More than 70% of the patients became sputum-negative and had cavity closure with this procedure.

Although thoracoplasty was for years a last resort, after the early stages of its development it was not a particularly dangerous operation. The entire Glen Lake series 1922 through 1967 on 1,251 patients in 2,976 operations shows there were 45 deaths from all causes within eight weeks of surgery; this is a 3.7% mortality per patient or 1.51% per operation. Patients soon learned not to fear the operation and many begged for it even when totally unsuitable.

The hazards of thoracoplasty were not always confined to the patient. Many years ago in Colorado, Webb brought Edward Archibald of Montreal to Colorado Springs to perform a thoracoplasty on a very ill patient, the wife a very wealthy South American. For several days the husband carried a gun in his pocket with the intention of killing the surgeon should his wife die. Archibald returned to Montreal before she expired.

Thoracoplasty was not uniformly successful,

some cavities did not close, some empyema pockets were not completely obliterated, and some patients did not become sputum-negative. Many factors brought this about, rigid chest, inadequate rib resection or long stumps, delay between stages because of the patient's condition or wound infection. Subsequent revision of the thoracoplasty with or without subscapular packing reclaimed a number of these as reported in a publication by this author in 1935.[205] It was long and rough treatment but did rescue some of the thoracoplasty patients and render them negative.

The results obtained by thoracoplasty were solid and permanent. I still see many of these "old-timers" whose surgery dates from the thirties and later, and have one dating from the fall of 1923. They have lived active, useful lives and many without much handicap. Many have gone through major surgery, pregnancy, pneumonia and other serious illness without difficulty. It was a good operation before something better came along.

With the advent of effective chemotherapy and experience in pulmonary resection, revision of unsatisfactory thoracoplasty was no longer considered, but lobectomy or pneumonectomy was done instead. Pneumonectomies under thoracoplasty were carried out over the years with a low risk.

Drainage of Tuberculous Cavity

Surgical attempts to treat tuberculous cavities have been made for many years. Blegney[32] in 1670 records a case of phthisis cured by a sword thrust puncture of an abscess of the chest. It is unkonwn whether this was empyema or cavity. E. Berry,[25] an Irish surgeon in 1726, reported several cases of direct drainage of tuberculous cavities. Purmann[319] in 1692 advised incision of the chest wall in hemorrhage, empyema, pulmonary cavities and all effusions. Baglivi[14] in 1710 treated wounds of the lung by free incision and advised the same for treatment of tuberculous cavities and cites cases with recovery.

Murphy[283] in 1898 discussed open drainage of tuberculous cavity advising resection of three ribs, drainage with cautery and packing with iodoform gauze. He felt, however, that tuberculosis was a medical not a surgical disease. The results of cavity drainage were not too encouraging so the procedure was avoided for some time until Monaldi[279] in 1938 from the Carlo Forlanini Institute in Italy revived it with his catheter suction drainage.

The new treatment was eagerly accepted by patients and phthisiologist alike and tried in many locations. Some became enthusiastic, other disappointed, in the results obtained. As experience accumulated a number of series were reported. Woodruff[430] of Saranac Lake in 1945 added a Stedman pump for continuous suction and reported on 100 patients treated from 1940, to 1947,[431] feeling it was a salvage procedure as a preparation for other collapse. There was much discussion, many disagreeing with this view. He also reported in 1945 that only four of 13 cavities so treated remained closed after the catheter was withdrawn. Head[361] of Chicago in 1946, also using a Stedman pump suction, reported that after three years only 16 of 29 patients so treated were still alive and that it rarely closed the cavity. L. Davidson[163] in discussion stated that he "hoped this paper was the obsequies of the Monaldi procedure." Monaldi in 1947 stated that there were no dangers in the procedure as an independent operation but that it was more valuable with collapse. Head, Vineberg, Wells and Gardner disagreed and used it only as a salvage procedure.

Monaldi drainage was first established at Glen Lake Sanatorium by Victor K. Funk[120] in 1924 for the relief of cough and to decompress a large tension cavity in the hope that cavity closure might later be obtained by thoracoplasty or other means. The possibilities of complete closure by the treatment alone were not anticipated. Over the next six years, only 14 procedures were carried out on nine patients. No cavity closures were observed, but reduction of cough and cavity size were observed. If thoracoplasty was anticipated at a later date, resection of a couple of ribs under local anesthesia at the site of the proposed catheter insertion was done a couple weeks before the Monaldi procedure so that the later thoracoplasty could be done without entering contaminated territory. No cases were done after 1948. I know of no other series of this type in Minnesota.

Resection for Tuberculosis

The idea of surgical resection of tuberculous lesions had long appealed to both phthisiologist and surgeon, but early results were less than encouraging. Two resection by Kronlein[220] in 1884 ended fatally. Biondi in 1882 experimented on pulmonary resection and recommended it in Tuberculosis. Rugge in 1885 did two cases, both of

whom died. Doyen[89] in 1893 performed a successful partial lobectomy on a 10-year-old girl. Likewise, Macewen removed almost a whole lung for tuberculosis. The patient was well 45 years later. Lowson[253] of London in 1893 resected a right upper tuberculous lesion successfully pulling the lung out through the incision, transfixing it, excising the lesion and later draining an abscess. The patient recovered. Doyen[89] in 1895 again successfully resected a small part of the lung for tuberculosis. Undoubtedly there were other unsuccessful attempts and many tuberculous complications unreported if we can judge from later experience before chemotherapy was available.

Friedlander[115] of Cleveland reported a successful resection of a cavitary right upper lobe for tuberculosis done in 1934. The patient, a 15-year-old girl, had the resection with a Bethune tourniquet and suture using closed drainage. A bronchial fistula developed three weeks later but closed gradually. Leo Eloesser[100] reported having done a lobectomy for bronchiectasis followed by a thoracoplasty for tuberculosis with recovery. Berge[100] reports a case of a pneumonectomy for tuberculosis in 1935 under a thoracoplasty done six years previously with a good result. John Alexander[100] warned against this procedure because of the risks from spread of tuberculosis. A case of mine in 1937, a total pneumonectomy[351] done by individual ligation for a very extensive bronchiectasis with more than 20 negative sputum smears and three negative guinea pig innoculations, was well tolerated but she died of a disseminated tuberculosis six weeks later. The excised lung showed plenty of tuberculosis in spite of the negative tests. What a difference antibiotics might have made.

We carried out a left total pneumonectomy[351] by individual ligation technique without any antibiotic aid in 1940. A nontuberculous empyema requiring catheter drainage and thoracoplasty complicated her recovery. Later silk bronchial sutures were removed bronchoscopically. She enjoys excellent health to date. Two other resections were attempted at Glen Lake but could not be completed because of technical and anesthetic difficulties.

Small series were reported over the next few years but in 1939 Dolley and Jones[87] from the literature were able to collect only 90 cases. Moore[75] by May, 1948, could collect 616 cases with an operative mortality of 15% and a total of 26%. The mortality for lobectomy was higher, 31.5%, than pneumonectomy, 24%, 12% developed empyema. Moore using a prone position reported spreads in 1.6% as contrasted with 14% for other positions. Gale[132] of Madison in 1948 reported a 25% mortality for lobectomy and 45% for pneumonectomy. Overholt in 1947 cited 16% spreads following upper lobectomy and thoracoplasty but 50% where no thoracoplasty was done.

Clagett[384] in 1947 before the Pembine Conference of the Chest Physicians and Surgeons from Michigan, Wisconsin and Minnesota presented a review of his first few pulmonary resections for tuberculosis with favorable results. He was castigated for even attempting to do these. The next year at Pembine Wm Seybold,[384] his associate, presented the continuing series also with good results and few complications, and he in turn was severely criticized for not doing more cases. Ellis.[98] Clagett and Carr in 1951 reported on a 10-year study of 35 cases with upper resection with thoracoplasty with no operative deaths and only one late fatality.

Mass ligation or tourniquet amputation, although used in many of the early resections of the lung, really had no place in tuberculosis resections for it leaves tuberculous disease and probably some necrotic or devitalized lung in the stump. Nearly fifty percent of the patients so treated developed empyema. Although H. Morrison Davies[76] of England did a resection by individual ligation in 1912, it did not become in general use until Churchill in 1931, Rienhoff[326] in 1933, Kent and Blades[200] in 1940, and Boyden[38] in 1945, and others emphasized the segmental anatomy of the lung and the advantages of resection by this method. Fewer complications and a smoother convalescence resulted.

Resections of the lung for tuberculosis before the days of adequate drug therapy could only be carried out with a prohibitive mortality. Dissemination of tuberculosis was the big risk. Under intensive chemotherapy with proper drugs the risk became comparable to that for nontuberculous disease. This became another tool to hasten and make more certain the patient's recovery from tuberculosis.

Locally we had a unique opportunity in the treatment of tuberculosis as the most experienced in the collapse therapy field and in pulmonary resection for nontuberculous conditions. We had the team and equipment to extend these procedures to tuberculosis. With adequate coverage by antibiotics for secondary organisms and now with the newer drugs against the tubercle bacilli a vast field opened up. Glen Lake Sanatorium with 680 beds, the Minnesota State Sanatorium with 240 beds, Nopeming Sanatorium near Duluth with 300 beds, the North Dakota State Sanatorium with 350 beds (40 for Indians), the smaller county or district institutions of Minnesota with 461 beds, the 115-bed Indian service at the State Sanatorium and the large Indian populations of North and South Dakota furnished a large reservoir of patients needing pulmonary resections.

St. Mary's Hospital, Minneapolis, provided adequate hospitalization for patients with tuberculosis under room isolation and had complete operating facilities, anesthesiologist services and trained nursing personnel for postoperative care.

The handling of the surgery for the smaller sanatoria during the period when thoracoplasty was the chief type of operation done from 1936 on was met by referring some to Glen Lake under special arrangements. The others, including those from South Dakota, were admitted to St. Mary's Hospital in Minneapolis under room isolation with stages scheduled ten to fourteen days apart depending on the patient's condition. For several years we kept one wing of thirty beds occupied most of the time. The thoracoplasties for the Minnesota State Sanatorium were done by the author traveling to that institution by car at first, but with gas rationing by train and later by bus every two weeks for two days during which time from three to five patients were operated upon. Most of the work was done under local anesthesia though an anesthetist was also present at the head of the table. The local medical and nursing staffs were trained in postoperative care. The North Dakota State Sanatorium during this period had a local staff trained in thoracoplasty.

When resectional surgery came into the tuberculosis picture, neither of these institutions were equipped to perform this type of surgery. The Minnesota Sanatorium transported its white patients to Glen Lake Sanatorium and its Indian patients to St. Mary's Hospital because they were carried under a different budget. The state-owned ambulance brought two patients at a time accompanied by a trained attendant in addition to the driver. They planned to return in one week with two more patients and return the original pair. With few exceptions this was possible though occasionally if the patient's condition warranted he would be held over for a later trip. The trip was 200 miles each way.

The North Dakota problem was more complicated. The Sanatorium near Dunseith in the Turtle Mountains on the Canadian border was about 600 miles from the Twin Cities. The first 50 miles was by ambulance to Rugby to the Great Northern Western Star train which took them on to Minneapolis where they were met by a local ambulance. This last step became necessary when a couple of Indians disappeared between the train and the hospital into the jungle of bars along Washington Avenue. The police later picked them up. One Indian escaped from the train coming down by diving headlong from the moving car. The track crew found his remains a day or so later. By and large they were good patients once they learned to know the staff and realize that we were trying to help them. Even the children were "dead pan" when first met but later became jolly and liked to laugh and joke.

The Indians presented a unique problem in the Tuberculosis program. Poverty, crowded housing, poor hygienic conditions, alcohol and a restless disposition all contributed to a high incidence of disease. The old idea that they had poor resistance to tuberculosis was disproven by Sanatorium experience which demonstrated that under adequate treatment they controlled their disease just as well as the white patients. It also established the fact that they could not be trusted to take the cure except under close watch—running away for fishing, hunting, pow-wows and other celebrations on the slightest excuse. Both in and out of the sanatorium they could not be depended upon to take the drugs prescribed so that prolonged chemotherapy was out of the picture. The above facts precluded the use of pneumothorax and other temporary procedures. Our program then called for thoracoplasty and other permanent procedures in the early days and intensive chemotherapy followed by resection of any cavity or dense lesions which did not respond rapidly and completely. The Indians were from

Minnesota, North and South Dakota and a scattering from Iowa, Wisconsin, Montana and Wyoming. The tribes included: Chippewa or Ojibway, Dakota or Sioux, and a few Menominee, Potawatomii, Oto, Sauk Fox, Arikara or Ree, Mandan, Absoraka or Crow, Cree, North Cheyenne, Shoshoni, and Arapaho. Over the years we have done resections on over 250 Indians.

An occasional language barrier was encountered among the older patients but they were usually sent down with another patient who could translate for them. The children were usually accompanied by a nurse from the home sanatorium. A few inmates from the state prison came with a guard but none caused any trouble. Most of the Indians tolerated their surgery very well and obtained good results, often in spite of themselves. Removal of the infectious ones from the community and eliminating the open cavities reduced the spread of the disease. The Indian building at the State Sanatorium has been closed now for a number of years.

Chemotherapy

The early history of antibiotics in the Twin Cities is largely the studies and reports of Wesley Spink[38] of the University of Minnesota. He introduced sulfa drugs to this area in 1937 and did extensive studies with them. In 1942 he did the same with Penicillin. His extensive studies with both drugs clearly defined their valuc, indications and reactions.

The early history of the anti-tuberculosis drugs, both locally and nationally, stems from the Mayo Clinic and the Mineral Springs Sanatorium at Cannon Falls. William Feldman, a veterinarian from the Experimental Institute at Rochester, Corwin Hinshaw of the Chest Department of the Clinic, and Karl Pfuetze,[310] medical director at the Sanatorium, became the team which studied, experimented and evaluated the experimental drugs as they became available for animal use and later applied them to patients. Promine was studied in 1941, Diazone in 1943-44. They were the first to report that it had little if any effect on clinical tuberculosis and did have serious toxic potentials. Promizole which worked well in guinea pigs was proved of no value in clinical tuberculosis. Streptomycin discovered by Schatz in 1944 and Para-aminosalicylic Acid (P.A.S.) by Lehmann in 1946 were studied in combination by this group in 1947-48. The preliminary laboratory and guinea pig work on all the drugs was done by Feldman who was most enthusiastic in his studies. This was not an individual project but rather a group study of many men from the Mayo Clinic including. Corwin Hinshaw, Davc Carr, Herman Moersch, Arthur Olson and Herbert Schmidt from the chest section, O. T. Clagett and William Seybold from chest surgery, Al Brown from ear, nose and throat, William Bickel, Paul Lipscomb, Mark Coventry and Herman Young from orthopedics and other consultants in neurology, urology and anesthesiology. For all the time, thought and effort expended by this group in this study, not a single one would accept a single penny in compensation, not even for the gas burned in the numberless hundred-mile round trips to the Sanatorium.

A 20-year-old girl in 1924,[88] became the first to receive an injection of Streptomycin. The first case of spinal tuberculosis to be treated anywhere with Streptomycin was also a patient there, the drug bringing about healing of tuberculous sinuses on the back permitting a surgical fusion to be carried out by Bickel.[88]

New antituberculosis drugs were thc result of extensive studies by many investigators. Oxytetracycline was reported by Bernstein in 1950-51; Isonicotinic Acid Hydrazide (I.N.H.) by Yeager, Benson and Fox in 1951; Viomycin by Finlay in 1951; Pyrazinamide, a synthetic by Kirschner, in 1952; Cycloserine by Harned and by Epstein in 1955; Ethambutal discovered in 1951 was released for clinical use in 1968. Cooperative controlled studies under the U. S. Public Health service were carried out in 22 institutions, including Glen Lake Sanatorium and the U. S. Veterans Bureau Facility in this area on large series of patients in order to evaluate the ability of separate as well as combined programs to control tuberculosis in new, retreatment and resistant cases.

The impact of ordinary antibiotics upon medicine and surgery can scarcely be realized. Many diseases were promptly controlled and others improved. Surgical infections were reduced or more easily controlled. The tuberculosis field was even more favorably influenced. Tuberculous meningitis which previously had been almost 100% fatal now could be controlled. Pulmonary tuberculosis, even extensive disease, may be effectively arrested in one-third the previous time

period and with more certainty. Surgery, especially resections, became much safer and paradoxically the indications much fewer. As a result the sanatoria developed vacancies in place of waiting lists and all but four in the state were converted to other use. The prophylactic use of INH in children and recent tuberculin converters has now become common practice. The U. S. Veterans Bureau Hospital and Armed Services Group studies on Tuberculosis and malignant disease has aided materially in the better utilization of the available drugs.

Traumatic Rupture of the Bronchus

Traumatic rupture of the bronchus or trachea is an uncommon but very serious type of injury. First reported by Winslow[428] in 1871 as a healed lesion found in a wild canvas-back duck, Seuvre[367] reported the first human case in a human fatally injured in 1873. The next 18 cases to be reported were all fatal until Krinitzki[218] in 1928 reported the case of a woman who died of pulmonary tuberculosis 21 years after a severe chest injury. The right main bronchus was completely obstructed with no evidence of tuberculosis in that lung. Subsequent to 1942[209] there were twelve patients who recovered slowly after decompression of the tension pneumothorax, the lung remaining atelectatic. All of these patients had sustained severe crushing injuries to the chest with or without rib fracture. The bronchial injury was usually a clean transverse section of the main bronchus close to the trachea, with the vessels intact. Rarely a similar section occurs in the trachea. The occurrence of this lesion should be suspected after a serious crushing injury with pneumothorax and cough with a little blood with or without mediastinal emphysema. Decompression of the pneumothorax followed by bronchoscopy will establish the diagnosis.

The first recorded case from Minnesota was reported by Jones and Vinson[189] of the Mayo Clinic in 1939 with bilateral pneumothorax aspirated repeatedly with recovery leaving a stenotic left main bronchus and atelectasis. The three patients[209] with stenosis and atelectasis whom we have seen recovered when treated as above. One subsequently had a pneumonectomy when the lung became infected. Another patient with bilateral tension pneumothorax and a fractured bronchus on the right survived with bilateral suction catheters. The bronchus was wide open and in good position for healing. In spite of all efforts to keep it patent with a seton and bronchoscopic dilatation, it went on to complete obstruction and atelectasis. Metastatic malignancy ended the picture without any further surgery. The ideal treatment after early diagnosis as soon as the patient can tolerate thoracotomy is to expose and do a primary suture of the bronchus or trachea.

N. K. Jensen[185] in 1953 successfully repaired a fractured bronchus at the Minneapolis General Hospital and later that year repaired a fractured trachea. He also repaired another bronchus at Northwestern Hospital[293] in 1949 and another in 1960.

Late excision of the stenotic area in the bronchus and direct anastomosis has been done and followed by re-expansion and function of the lung.

Chest Tumors

Tumors of the chest and mediastinum undoubtedly were more common than were recognized because many, especially those of an intrathoracic position, gave few or no symptoms until they reached some size or interfered with some structure. Hedblom[165] of the Mayo Clinic in 1921, totaled the reported cases at 213 to that date. He presented a very complete review of the subject with an extensive bibliography. He quoted von Speicher[379] of 1881 as collecting 28 cases, Parham[302] of New Orleans in 1898 with two cases of his own and 101 collected cases, and Lund[255] in 1913 adding 27 additional collected cases and one of his own. Hedblom in this report added 35 more cases from the literature, added 23 operated cases from the Mayo Clinic since 1910, and an additional 25 cases from the Mayo Clinic in which no surgery was done, for a total to that date of 213. From this group 62.8% were sarcoma and 8% chondrosarcoma; 167 or 78.7% involved the ribs, and 41 or 21.3% the sternum. He demonstrated one case of a melanoepithelioma of the manubrium operated upon twice but lost after six months from the recurrence. He quoted Parham[302] for crediting Oaias Aimer with the first thoracotomy for tumor in 1778.

Carl A. Hedblom[168] in 1933, then in Chicago, reported on intrathoracic dermoids and teratoma

collecting 185 cases from the literature and adding six personal cases. S. W. Harrington[156] reporting from the Mayo Clinic in 1929 on surgical treatment of intrathoracic tumors, added 12 to the five he had listed previously; 15 were completely removed, eight were malignant. By 1931 he reported on 28 cases in the lung and mediastinum, 14 were malignant and 14 benign. He later listed 11 cases of intrathoracic teratoma in five years, ten in the mediastinum and one above and below the diaphragm. The relatively small size of these series in comparison to the Mayo Clinic' volume of cases registered emphasizes the relative infrequency of these tumors.

Kronlein of Zurich in 1884[220] reported the removal of a tumor of the chest wall and attached lung from an 18-year-old boy who recovered and was apparently well two years later.

The earliest local record of intrathoracic tumor we have been able to find was presented before the Minnesota Academy of Medicine, 1888, by J. Clark Stewart.[387] It was a huge anterior mediastinal tumor displacing the sternum and obstructing the mediastinal structures. It was not amenable to surgical removal. It proved to be a small-cell sarcoma at postmortem examination.

With the advent of statewide chest x-ray surveys in Minnesota in 1946-48 and in North Dakota in 1946, South Dakota from 1949 to the 60s and routine hospital chest X rays, many unsuspected and usually asymptomatic tumors of various kinds were discovered. These surveys over a period of time brought to us, referred from physicians throughout the territory, a large number of chest tumors numbering well over three hundred. The most frequent tumor of the anterior mediastinum was the teratoma and its dermoid variety while posteriorly it was the neurogenic tumor. These tumors form the basis for my book, "Tumors of the Chest"[211] published in 1963. The charts, copies of Xrays, Kodochromes of specimens, and tissue sections are preserved in a special section of the medical Library at St. Mary's Hospital in Minneapolis. I did the photography.

Bronchogenic Carcinoma

Bronchogenic carcinoma, that perennial mimic of the pathological field which has been present long before it was recognized, still masquerades as pneumonia, viral pneumonia, tuberculosis and a variety of other conditions. Unrecognized as cancer amongst the Schneeberg miners of Uranium ores in the middle ages, it was first proven pathologically by Morgagni[280] in 1761. Bayle in 1810 first described cancer and tuberculosis in the same patient. Laennec later was able to differentiate the two conditions. Bell in 1846-7 was the first to make the clinical diagnosis of a primary lung tumor though it was later called a sarcoma, a diagnosis which even today may be open to question. The pathological studies of Rokitansky[342] and Virchow aided in the differentiation from other lung conditions. The monograph of Adler[2] in 1912 was the first extensive American publication on the subject. He listed 374 collected cases and called it forcibly to the attention of clinicians, in spite of which it was rarely considered in differential diagnosis.

Moses Barron[20] from the pathology department of the University of Minnesota in 1922 reported that 13 cases were found in 4,362 postmortem examinations, an incidence of 0.29%. The Minneapolis General Hospital reported 14 cases diagnosed in 1935-39 from 26,301 patients registered, an incidence of 1 per 1,878 admissions (0.53%)

The question must arise as to how many cases were unrecognized. I well recall while an intern at the Minneapolis General Hospital in 1919 three cases which came to postmortem examination presenting extensive carcinomatosis with metastasis to liver, adrenal and other organs plus a lung lesion. They were signed out as carcinoma, primary site, probably liver or bile ducts because of the extensive liver involvement.

Glen Lake Sanatorium[131] from 1916 to 1939 reported 17 cases from 6,343 admissions, an incidence of one in 373 patients who for admission must have had at least a tentative diagnosis of pulmonary tuberculosis in order to be received. Even in 1941 at the chest service conference of the Veterans Facility, the reaction when a suggestion was made that a certain case might be carcinoma instead of tuberculosis was that carcinoma was a very rare disease which they never encountered. The publication of Edwin J. Simons' book, "Primary Carcinoma of the Lung,"[374] in 1937 did alert the local profession to this disease. Simons, a rural practitioner from the small town of Swanville, Minnesota, (population 435) became interested in the subject because of the

occurrence of two cases in his practice within two years, one a 19-year-old boy.

One of the most important requisites to making a diagnosis of bronchogenic carcinoma is a high index of suspicion and tenacity in following through to establish the diagnosis or rule it out. A battery of special tests may be necessary including some of the following: Xrays, planigrams, cytology studies on sputum and bronchial washings, bronchoscopy and biopsy, prescalene or mediastinal node biopsy.

Its surgical treatment is of recent origin. Kronlein[220] in 1884 reported resecting a section of the chest wall and attached lung in an 18-year-old girl who was apparently well two years later. I suppose this diagnosis might be questioned. Kummel from Germany in 1910 carried out a pneumonectomy for carcinoma by mass ligation but lost the patient on the sixth day. H. M. Davies[76] of England in 1912 did a lobectomy for carcinoma by individual ligation, the patient dying on the eighth day from empyema. He advised exploratory thoracotomy.

Adler[2] in 1912 could collect only 211 cases before 1900. Sauerbruch[355] in 1920 reported two cases of partial resection. Lillienthal[247] in 1924 resected a lobe but preferred pneumonectomy. Allen and Smith[7] in 1930 reported a patient who lived four years following a lobectomy for carcinoma. Tudor Edwards[94] of England in 1932 reported good results in a case of squamous carcinoma with a small excision followed with Radon implantation. Later the growth was gone. Churchill[56] in 1933 reported a lower and middle lobe excision for carcinoma. Reinhoff[326] in 1933 reported two pneumonectomies by individual ligation through an anterior approach. Reinhoff and Broyles[327] in 1934 reported resecting one carcinoma and one sarcoma with good results. Egger[27] in 1934 reported one lobectomy. Rabin and Neuhof[323] reported five lobectomies, one of whom was alive one year later. Archibald reported two with good results. Young had one left upper lobectomy patient who was well one year later. Andrus[11] in 1935 reported six cases treated by cautery excision with three alive two, two and one-half, and three years later. Evarts Graham[141] of St. Louis carried out the first successful total left pneumonectomy for carcinoma in the United States on April 3, 1933, doing a mass ligation excision and a concommitant thoracoplasty. The patient, a physician, not only recovered but resumed practice and outlived his surgeon. Overholt[299] later in 1934 reported the second successful pneumonectomy in America and in 1935[300] recorded 13 patients so treated, seven for metastatic disease and six for primary carcinoma with three recoveries. Bigger[27] in 1935 reported one successful lobectomy and one pneumonectomy patient who died of suppurative pericarditis. Ochsner[294] on April 15, 1936 reported his first case, the tenth successful one on record. Churchill[57] in 1937 recorded three total pneumonectomies. Reinhoff in this same year added six more cases. Churchill[57] in 1938 added a conservative view to the picture showing that lobectomy often gave as good results as pneumonectomy and with a smaller risk. Allison[9] of England in 1950 presented a more radical view advocating radical pneumonectomy rather than the ordinary operation in spite of its increased risk and complications.

Harrington[161] from the Mayo Clinic in 1935 after a preliminary thoracoplasty did a pneumonectomy for carcinoma; unfortunately, the patient died postoperatively of respiratory and cardiac failure. In 1937, at Northwestern Hospital I carried out a left total pneumonectomy by individual ligation on a 62-year-old man for squamous cell carcinoma for the first successful pneumonectomy for carcinoma in Minnesota. His convalescence was uneventful and he lived 13 years and nine months, dying of hypertensive cardiovascular disease without any evidence of recurrence. Harrington[161] in 1941 made a report of the Mayo Clinic to that date listing 31 cases, of which 21 were explored and found non-resectable, nine had pneumonectomy in one stage, three dying after surgery with five alive at three to eighteen months after resection. Brindley[58] and Clagett in 1943 reported 95 cases explored with 45 resected. The mortality from pneumonectomy was between 10 and 15%. Geha, Bernatz and Woolner[126] from the Clinic in September, 1967, reported that of 2,113 patients with bronchogenic carcinoma explored, 174 had tumor invasion of the chest wall, in 14 of whom the involved area was resected in conjunction with the involved lung. N. K. Jensen[186] in discussion mentioned that of 1,000 cases collected from their files, 700 were explored and 475 resected, and that of 18 who had chest wall invasion resected, six survived for five years.

John C. Jones et al.[191] in 1967 reported that in

the United States in 1967 it had been predicted that 42,000 males and 8,000 females would die of lung cancer. He also stated that of 358 patients resected between January, 1937, and July, 1967, there were 94 patients who survived five years, 264 died within five years, an average survival of 13 months. Before 1950 all patients had pneumonectomy, later 30% had lobectomy; the operative mortality was 1.7%, the thirtieth day mortality, 6.2%. Overholt[301] in discussion listed 2,657 cases with 70% explored, 49% resected. There were 191 five-year survivals, 91 by pneumonectomy, 79 by lobectomy and 21 by segmental resection.

The long term prognosis from bronchogenic carcinoma is always uncertain. The author recalls one patient,[351] a 71-year-old hard rock miner with extensive silicosis and a squamous cell carcinoma of the left lower lobe. A left lower lobectomy was done. The local lymph nodes were involved with carcinoma, a hard mass in the lower mediastinum could not be removed. He not only recovered but survived for twenty years, dying from Cor pulmonale without recurrence. Did silicosis block the lymphatic spread of his tumor?

Mediastinoscopy and Pre-Scalene Node Biopsy

Daniels[74] in 1949 described a new method of biopsy useful in certain types of intrathoracic disease. It consisted of excision of the fat pad and lymph nodes overlying the scalene muscles in the low cervical region. Confronted with intrathoracic disease with a suggestion of possible mediastinal lymph node enlargement it offers a chance of obtaining tissue for microscopic diagnosis for the lymphatics in the prescalene have a direct connection with those of the mediastinum. The finding of carcinoma in the lymph nodes in this area would prove the noncurability of a carcinoma of the lung and the futility of resecting the lung lesion with any hope of cure. Tissue obtained from this region may establish a diagnosis of sarcoid the most common finding, or tuberculosis, silicosis, or lymphoma. Slowly it became accepted and later became widely used. It is a low risk procedure which often furnishes valuable information.

Dwight Harken[153] of Boston in 1954 described a simple cervicomediastinal exploration for tissue diagnosis of intrathoracic disease. Through the same incision used for prescalene biopsy, he inserted a finger into the upper mediastinum, dissecting the loose tissues anterior to the trachea and through a small laryngoscope visualized, aspirated and biopsied or excised lymph nodes deep in the mediastinum. He had done over 300 such operations at the time of his report, encountering bleeding easily controlled with gelfoam and a small pneumothorax on two occasions. Positive carcinomatous nodes were obtained in 85% of cases of bronchogenic carcinoma.

Eric Carlens[48] of Stockholm, Sweden, in October, 1959, described a similar procedure carried on through a small transverse incision in the midline just above the manubrium under local or general anesthesia. R. Rynders[346] of Amsterdam in June, 1964, reported on 250 such procedures since 1960 with only two complications, a right recurrent nerve interruption and one instance of bleeding easily controlled by packing. Carlens in 1964[48] reported the method 94-100% accurate in sarcoid. A number of local thoracic surgeons and bronchoscopists are now doing the procedures. Duval, Johnson and Koop[188] of Minneapolis in July, 1968, have reported on over 100 cases with no complications. Pearson[307] of Toronto has recently given an evaluation of Mediastinoscopy in the management of presumably operable bronchogenic carcinoma.

Surgery of the Esophagus

The esophagus presents a number of conditions which may require surgery.

Foreign Body

Many of the foreign bodies in the esophagus may be removed endoscopically and have been considered under that heading. William Lerche of St. Paul in 1911 discussing foreign bodies in the esophagus warned against passing sounds to dislodge the offender. He stated that if perforation has occurred in the cervical region, one should not esophagoscope, if in the thorax one should pass the scope to determine the site of the abscess. He quoted Kohn as collecting 326 cases of cervical esophagotomy with a mortality in 1880 of 26% and from 1900-03 of 12.6%.

Perforation

Perforation is always a possibility with foreign body or even with the passage of a scope and can be a very serious condition. When I first joined the surgical staff of the Minneapolis General Hospital in 1936, there had been no recoveries following perforated esophagus. Over the next few years we operated upon seven pa-

tients with cervical perforations losing only one before the days of antibiotics. This man died of a brain abscess several days postoperatively. His perforation was over 24 hours old when he was first seen.

Pharyngeal Diverticulum—Zenker's Diverticulum

Pharyngeal diverticulum, often called Zenker's Diverticulum, although Ludlow[254] in 1764 first described the condition, is really a herniation of the pharyngeal mucosa through a weak spot or defect in the midline just above the cricopharyngeus muscle, the Lannier-Hackerman area. Rokitansky[342] in 1840 described the condition and suggested dilatation for treatment. Nichaus[289] in 1881 is credited with the first extirpation. C. H. Mayo[267] in 1910 reported eight cases with one and two stage operations, with two postoperative fistulae and warned of the danger of aspiration during operation. He mentioned one case with a sac which held sixteen ounces of fluid. This author had one patient a number of years ago who was referred in as a mediastinal tumor but whose diverticulum extended into the upper mediastinum and held over a pint of barium. DeWitt Stetten[385] in 1910 stated that Kluge in 1894 suggested excision. The earlier operations included invagination of the sac, elevation and suture of the sac to facilitate drainage before secondary excision and two stage excision. Soon, however, only the one stage resections were done and many general surgeons were doing this type of work.

Pulsion diverticula in the lower third of the esophagus are seen occasionally and in the absence of symptoms and obstruction at the cardia are usually not treated. When necessary they may be excised through a left low posterior thoracotomy in one stage by a similar technique to that used in the cervical region.

Traction diverticula usually found in the mid esophagus result from drainage of a suppurating lymph node into the adjacent viscus. If necessary, which is rarely, they may be treated by excision of the adjacent nodes and suture of the fistulous tract.

Achalasia of the Esophagus

This condition was first described by Purton[320] from the postmortem findings in 1821. Megaesophagus of achalasia, a term introduced by Hurst, should replace cardiospasm as formerly used because the condition is due to a disturbance in motility of the involved organ rather than a spasm of the local esophagogastric junction. The broadening of the mediastinal shadow seen on single x-ray films is frequently confused with tumor though the differential diagnosis is not difficult. Various treatments have been suggested, none of which is completely successful. Dilatation by passing small bulb dilators over a string guide rarely produces lasting relief. The use of the string guide was to Mixter's credit; was used by many (Plummer,[315] Vinson,[410] Lerche and others,) and added much safety to many intraesophageal maneuvers. A number of types of dilators for use in the esophagus were devised over the years, the mercury-filled Hurst type,[180] the Kohlman of Lerche, the air pressure dilator of Mosher and Sippy, the Mosher mechanical dilator and the Russell dilator of the hydrostatic type improved and used extensively by Plummer and Vinson[411] and their group. The forceful stretching of the narrowed area by the hydrostatic dilator afforded lasting relief to at least 75% of the patients so treated. The dangers of perforation were ever present but by first dilating to 60 French before using the hydrostatic dilator, the risk is materially reduced. Vinson[411] reported no fatal outcome in over 450 patients so treated. The operation of esophagoplasty suggested by Wendell in 1909 using a longitudinal incision of the narrowed segment followed by transverse closure may provide drainage to the dilated esophagus but may be followed by distress from regurgitation and at times corrosion esophagitis. More recently the Heller esophagotomy operation on the lower esophagus has come into favor in place of the older procedure. Sweet[390] in 1956 divided cases of achalasia into two groups. Type I (75%) show enormous dilatation of the esophagus with little peristalsis with a small lower segment with thin muscle layers. Type II (25%) show only moderate dilatation with active to hyperactive peristalsis and even reverse peristalsis with a thickened lower segment with hypertrophy of the musculature. Both show degeneration of the ganglion cells in the wall. Forceful dilatation or an esophagogastrostomy gives best results in Type I. Type II does better with an esophagotomy.

Esophagus

Spontaneous Perforation

So called "spontaneous rupture of the esopha-

gus" was first described by Boerhaave[35] in 1774 and over fifty cases were collected by a number of authors including Barrett[19] in March, 1946, and Eliason and Welty[97] in August, 1946. A report[210] on this condition in 1948 covers the whole picture and a complete record of the literature to date, together with a record of the five new cases seen to that date in Minneapolis.

The clinical picture, while not well recognized even to this date, is so characteristic that it has been diagnosed at least twice over the telephone, once by Wangensteen and once by this author. The first patient, at the St. Barnabas Hospital[210] died undiagnosed thirty hours after the onset and twelve hours after an exploratory laparotomy for suspected perforating ulcer. The second, a 16-year-old boy with poliomyelitis with severe repeated vomiting, also died without the diagnosis being made until the postmortem examination. A third case was diagnosed, the tension pneumothorax and pleural fluid removed, but in spite of supportive measures his condition never improved sufficiently to permit surgery. A fourth patient was seen nearly two and a half weeks after the onset of trouble, in desperate condition with left pleural effusion. The diagnosis was made; the chest decompressed and the fluid removed. His condition would not permit surgery although it was considered. The family decided to take him to Rochester where he had been a patient on several occasions. He died two hours after arrival. Postmortem examination revealed a longitudinal tear in the lower third of the esophagus. The fifth patient,[210] 67 years old, collapsed on the street and a few hours later was brought to the General Hospital in shock and very dyspneic. The diagnosis was made over the telephone while talking to the resident. He was operated upon promptly; over a quart of old food removed from the left pleural cavity and the esophageal rent sutured. Convalescence was stormy but he improved until the ninth day when he died of a pulmonary embolus. Two other cases were observed later with one recovery following early surgical repair, the other under antibiotic therapy without surgery. Drs. Olsen and Clagett[296] reported one patient in 1947 who was operated upon early with recovery.

One important fact has been learned in treatment of this catastrophe. Diagnosis must be prompt and thoracotomy carried out at once without waiting for supportive measures to bring up the blood pressure. Decompression of the tension pneumothorax, evacuation of the food and acid from the chest and washing the irritating material from the pleural cavity will be followed by return of the blood pressure while the surgery is in progress. The esophageal rent should then be sutured, and the chest closed with suction catheters. Antibiotics have improved the prognosis very materially. A review by O'Connell[295] of England in 1967 carried an extensive reference list.

The experimental reports of Wangensteen[421] and his group would seem to indicate that pyloric obstruction with regurgitation of the highly corrosive acid-pepsin stomach contents in the lower esophagus so weakens its wall that the force of the vomiting splits the wall in a longitudinal manner.

Esophageal Atresia and Tracheo-Esophageal Fistula

This condition was first described by Thomas Gibson in 1696, and was almost universally fatal until 1939. N. Logan Leven[238] of St. Paul in 1935 and 1936 operated upon two babies, the first, a four-day-old, first doing a gastrostomy with obstruction of the cardia by catheter. At a second stage cervical esophagostomy was done, connected to the gastrostomy by an external tube. The child died on the 98th day. The second done by a somewhat similar technique survived over 53 days.

H. M. Richter[328] in 1913 through a transpleural approach with a gastrostomy below had ligated the fistula using a mechanical respirator made with an old vacuum cleaner motor. The patient did not survive. Robert Shaw[369] of the University of Michigan in 1938 ligated and divided the fistula and made a primary anastomosis of the esophageal segments. The patient died on the 12th day. Paul Samson[348] did a similar case. Lamman[230] in 1936-37 did four cases by an extrapleural approach with primary anastomosis and another in 1939; all died though two lasted eight to nine days. Cameron Haight[151] of Ann Arbor, Michigan, five months after the Shaw report did a primary repair, the baby dying seventeen hours later. Within the next 23 months, two more were done by him and two by John Alexander,[4] but all died. They did not know then of the work of Leven and Ladd.

N. Logan Leven[240] in 1939 did the first successful treatment of tracheal-esophageal fistula with an initial gastrostomy and occlusion of the cardia. He then did an extrapleural approach with closure of the fistula and did a cervical esophagostomy. Much later a tube reconstruction was done. Ladd[226] later did tube reconstruction. Sweet[391] preferred reconstruction by bringing the stomach into the chest for anastomosis. Potts and De Boer[77] in 1946 reported four operations with 100% mortality. Ten years later[77] they reported 117 patients, doing a transpleural exposure, a two layer closure and without gastrostomy. By 1952 at the University and Ancker Hospitals, Leven, Varco, Lannin and Lyle Tongen[241] reported 103 cases.

Tague Chisholm[54] of Minneapolis did his first tracheo-esophageal fistula operation in 1947 and subsequently to 1968 has done 161 cases, losing 22 or 13.7% mortality which is remarkable considering the desperate condition of some of the babies when they arrive from distant sources.

D. J. Judd, Clagett, Havens and Moersch[194] of the Mayo Clinic in 1944 reported a man of 30 with an acquired fistula from a bullet wound cured by a two-stage operation. The total Mayo Clinic series 1916-65 was 36 cases. Wychulis,[432] Ellis and H. Anderson reported 14 cases since 1948 with 13 of 14 having an uncomplicated recovery.

The reviews of this subject by Anderson and Sabiston[10] in 1965, Sacks et al.[347] in 1965, indicate that the condition is not as rare as formerly supposed and can frequently be successfully repaired.

Carcinoma of the Esophagus

Carcinoma of the esophagus has posed serious problems to the medical profession for a long time. The slowly starving patient came, hoping for relief, which the doctor could not provide. Gastrostomy for feeding was poor palliation for though it provided for some nutrition, it afforded no relief from the continuing saliva and other secretions which were the most distressing part of the obstruction. Also, when used in the very debilitated patient it carried an appreciable mortality from lung complications from aspiration of secretions. Dilatation by means of graduated bougies passed over a string guide and repeated every few weeks often kept the strictured area open sufficiently to permit passage of liquid and soft food as well as saliva and secretions, until the patient succumbed to metastasis. Plummer[314] and Vinson,[410] Lerche[242] and Schwyzer[365] from this territory used this method for many years and contributed much to the handling of these unfortunate individuals. Adolf Kussmaul[223] in 1868 is credited with being the first to directly visualize a carcinoma of the esophagus by means of an endoscope. A. Schwyzer[365] of St. Paul also visualized carcinoma of the esophagus, made biopsies of it and used radium.

Vinson and Moersch[409] in 1925 stressed the relative safety of dilatation in carcinoma, three deaths in 502 dilatations contrasted to at least a 10% mortality for gastrostomy. Souttar[377] of England in 1924 developed his spiral German silver tube for intubation of the strictured carcinomatous area to permit feeding and swallowing of secretions. Symonds[392] and dePezzar tubes were also used.

Radiation for Carcinoma of the Esophagus

Radiation treatment for carcinoma of the esophagus has been tried by many since radium was first introduced, with varying results. We know that Arnold Schwyzer[365] of St. Paul used it as early as 1904. Deep therapy has been known to relieve the obstruction to a rather marked degree but was followed later by a marked stricture resistant to dilatation. Nakayama[286] in 1967 reported three of eight patients surviving over five years following radiation and surgical removal but does not state whether there was any node involvement, a most important consideration. Groves[147] of Cleveland in 1968 reporting on combined treatment of 37 patients with carcinoma of the esophagus and cardia, notes that 21 were adenocarcinomas, 13 were squamous and two undifferentiated carcinomas. The long survivors, 18-36 months, were all in the group without node involvement.

Theodor Billroth[28] in 1872 is credited with the first successful total resection of the stomach and lower esophagus for carcinoma. Mikulicz[276] in 1886 was the first to treat carcinoma of the esophagus by resection and plastic reconstruction. The patient died.

Carl Schlatter[362] of Zurich, while on a locum tenens for Prof. Kronlein in 1897, did a complete gastrectomy, the specimen showing duodenal tissue on one end and esophageal tissue on the other. He anastomosed the jejunum to the esophagus. The patient died 15 months later from recurrence.

Kendell Franks[112] is reported to have resected a localized nonmalignant stricture of the esophagus and performed an end-to-end anastomosis over a tube before 1899. Sir Berkeley Moynihan[281] of England in 1903 is reported to have done a total gastrectomy. Voelcker[412] in 1908 is reported to have anastomosed the esophageal stump to the jejunum after removal of the stomach. W. J. Mayo[268] in 1917 did a total gastrectomy and removed 16 mm. of the lower esophagus. Patient recovered and was doing well five years later. Hedblom[166] in 1922 in a two stage procedure resected the stomach for carcinoma of the cardia with 4 cm. of the esophagus; the patient surviving over five years. He first did an extensive lower left thoracoplasty, then later resected the tumor, bringing the stump of the esophagus out to the skin in the mid axilla and connecting it to a gastrostomy opening by means of a rubber tube.

These cases were undoubtedly cases of high gastric carcinoma and not primary carcinoma of the esophagus. Many others were probably attempted unsuccessfully.

Graham and Ballon[139] in 1931 stated there were no survivals of carcinoma of the lower third of the esophagus operated by the abdominal route. Franz Torek[396] of New York in 1913 performed the first successful resection of carcinoma of the thoracic portion of the esophagus. A gastrostomy was done first, then after resection of the anterior portions of ribs four through seven, the entire esophagus was resected bringing the cervical portion out through the skin. This stump was then connected to the gastrostomy opening by an external tube. Lillienthal[246] in 1920 using a new technique without a gastrostomy excised the tumor and joined the esophageal stumps by an extrapleural skin tube for the second successful case. Carl Eggers[95] in 1924 performed the third successful resection bringing the upper segment out through the neck, tunneling it to the second interspace subcutaneously from which an external tube was led to the stomach.

Dissatisfaction with the Torek type of procedure led to the development of a number of procedures to obviate the external rubber tube connecting the upper esophagus and the gastrostomy opening. For carcinoma of the pharynx and cervical esophagus Gluck[133] and Wookey's[429] operation involving excision of the tumor plus the larynx and construction of a skin tube to bridge the gap became standardized. For carcinoma of the lower third of the esophagus excision of the tumor, mobilization of the stomach through the diaphragm and anastomosis of the esophagus to the stomach elevated into the chest offered a one stage answer to the problem. Carcinoma of the remainder of the thoracic esophagus posed more serious difficulties. The stomach, jejunum and right colon were used to establish continuity. Yudin[436] and others in their articles illustrate many of the reconstructive procedures. These were placed intrapleurally, through an anterior mediastinal tunnel or through an anterior subcutaneous tunnel. Anastomotic leakage, infection and loss of blood supply to the transplanted segment, stricture and regurgitation were not uncommon. Infection was more serious in the intrapleural than in the subcutaneous area. Prognosis was related to the late stage of discovery, the amount of lymph node involvement and position of the tumor. The number of five year survivals was never great.

Surgery for carcinoma of the esophagus in the early days was not only hazardous but the results were far from encouraging. At the Minneapolis General Hospital,[278] 1940-47, we explored ten patients with involvement by squamous tumor. All were emaciated and in poor condition. Three were nonresectable. Six were resected using the stomach for re-establishing continuity, two well above the aortic arch. Three survived but died of metastases within the year. Three succumbed to infection and leakage of the anastomosis. Such results were discouraging so the procedure was not pushed. Phemister and Adams[1] of Chicago in 1955 reported on 475 patients with carcinoma of the lower esophagus and cardia seen between January 1, 1945 and December 31, 1952; 210 were inoperable, 256 were explored and 125 resected. The hospital mortality was 16.7%. Eleven survived five years. Among the 219 patients who were inoperable 88% were dead in one year and 97% in 18 months. Terracol and Sweet[391] in 1958 reported 20% survival in five years from cervical carcinoma, zero for superior mediastinal tumor, 23% for mid-thoracic tumor and 32% for lower segment carcinoma. Dietrich,[84] Dockerty, Olsen and Ellis from Rochester in 1963-64 discussing the lower segment tumors, reported seven of 13 squamous cell carcinomas survived more than five years, with only 13 of 120 adenocarcinomas alive in five years. Although much has been ac-

complished over the years in spite of many discouraging experiences and much reason for pessimism, it is well to remember that every one saved is truly a brand from the burning.

Wangensteen[422] and his staff of the Surgical Department at the University of Minnesota Hospital became interested in this problem in the late thirties or early forties, and soon encountered the same complications which others had found, but characteristically they turned to the laboratory for their answers. Esophagitis, leakage, poor healing, ulceration, stricture, hemorrhage and perforation were the result of acid-peptic digestion from regurgitation of stomach contents which could not move on because of pyloric closure following the vagotomy incident to mobilization of the stomach and esophagus. Pyloric myotomy or pylorotomy plus partial gastric resection were soon added to the procedure to correct the situation. Retrograde suction through the duodenum to keep the stomach empty of acid secretions and a jejunostomy feeding tube to supply nutrition to the very debilitated patient were well worthwhile. They came to a mid-sternal approach to the right pleural cavity for the reconstruction. Later the right colon was considered a better replacement for the esophagus than the stomach or jejunum. By 1956 they had five patients surviving and apparently well six or more years following resection for lower third tumors.

The recent report of Humphrey and Clifton[178] from Memorial Hospital in New York reviews their entire series of 592 patients seen from 1926 to 1961 and includes both epidermoid and adenocarcinoma; 154 patients received no treatment or only gastrostomy; 188 or 31.4% received irradiation; 387 or 65% were explored, and 243 or 41% underwent resection; 17 patients with epidermoid tumors were treated by colonic bypass with a 5.5% mortality. No untreated patient survived more than two years and only 16% more than six months. All untreated patients with epidermoid tumors were dead within ten months. The operative mortality for resection for epidermoid carcinoma was 21.6% while that for adenocarcinoma was 27.1%. The long term survival for resected epidermoid carcinoma with positive node involvement was 28% for one year, 11% for three years and 2.8% for five years. The long term survival for those without nodal involvement was 50% for one year, 25% for three years and 14% for five years.

Recently T. Peterson, F. Johnson[309] and Kiser reported a local series of thirty patients with carcinoma of the esophagus or high gastric carcinoma upon whom resection of the tumor was carried out from 1956 to 1966 with reconstruction by esophagogastric anastomosis in the pleural cavity. There were four postoperative deaths, 13%, three late hospital deaths, 10%. Eleven were alive without evidence of tumor, four for over five years. Eleven (36%) died from metatases within eleven months.

The recent report by Fry,[117] Grein and Adams of Chicago on carcinoma of the upper esophagus with malignant tracheo-esophageal fistula treated by radiation followed by surgical excision with no recurrence four years later is encouraging and might give rise to the hope that with combined therapy a less pessimistic attitude might be justified. A review of the whole picture with all factors evaluated indicate that carcinoma of the esophagus presents a less dismal outlook now than previously. Certain facts stand out. The stomach is not the ideal substitute for the esophagus following resection. The right colon is available and retains its blood supply better than the jejunum and can be used more safely. Irradiation has been a factor in prolonging survival time with and without other treatment, and its use is to be encouraged. Earlier diagnosis and an aggressive attitude towards epidermoid carcinoma by surgery and irradiation has considerable to offer for this otherwise hopeless condition.

Pericarditis and Constrictive Pericarditis

Disease of the pericardium apparently was recognized long before anything was done about it. Roilan[341] in 1649 suggested incision and drainage of the pericardium through a trephine opening in the sternum. Senac in 1749 suggested drainage through an incision to the left of the sternum. Romero[343] in 1819 apparently did the first successful pericardiotomy recording two recoveries in three cases. Jowett[193] in 1827 did a transpleural trocar drainage allowing the fluid to escape into the pleura from which it was absorbed. Karanoff[198] in Russia in 1841 successfully drained a series of patients with effusions from scurvy (bloody effusions?). Hilsman[173] in 1844 was the first to drain suppurative pericarditis through a left fourth interspace incision. Langenbeck[229] did the same in 1850.

Del Vecchio[79] in 1895 demonstrated in dogs that heart wounds heal following suture. Fischer[108] collected 452 cases all but 72 fatal. Tuffier in 1920 collected 305 cases from which 50% recovered. The status of such procedures at that time was expressed by Billroth's[29] description, "A Surgical Frivolity. No surgeon who wished to preserve the respect of his colleagues would ever attempt to suture a wound of the heart."

Beck[21] in 1925 noted several points. Blood in the pericardium absorbed rapidly and left no adhesions. Tamponade occurred from very rapid formation of fluid and not from slow formation. Drainage was not desirable except to the pleura.

Delorme[80] in 1898 suggested decortication be done for constrictive pericarditis the same as in the trapped lung but it was not carried out. Brauer[40] in 1902 resected the overlying ribs and cartilages in an attempt to relieve the situation. The patient was well eleven years later. Rehn[325] in 1914 was the first to report the results of partial pericardiectomy.

Sauerbruch[355] reported one case done in 1913. Churchill[55] in 1929 reported the case of an 18-year-old girl operated upon in July, 1928, resecting five cartilages and the left half of the sternum decorticating an area the size of the hand freeing the auricle and elevating the heart. He collected 37 cases with seven deaths and 50% excellent results. Harrington[160] in 1940 reported on nine cases with three cured, three improved and three deaths from 1936-1939. Later in 1944,[162] the series was up to 44 cases with a 25% mortality, three cases were tuberculous. Claude Beck[24] in discussion reported on 51 operations on 46 patients with 67.4% cure. There were 26% early and late deaths. George J. Heuer[170] reported 14 of 18 patients cured or markedly improved. Wangensteen[419] in 1932 reported on his first three pericardiectomies. Clagett, Kirklin and Cooley[63] in 1958 reported on the entire Mayo Clinic series of 72 patients from 1935-1955 with essentially complete removal of the peel in 65 cases. Eleven of the patients showed granulomatous changes suggestive of tuberculosis of whom six had positive cultures. Stanley Maxeiner[262] and this author independently carried out a small series of this type of surgery in the private hospitals in the early forties.

Josiah Fuller[118] of Duluth carried out the first pericardiectomy at the Head of the Lakes in 1957.

Patent Ductus

Persistent Ductus Arteriosus was recognized by Galen A. D. 131. Botallo, due to a mistranslation by Van Horne in 1660, has been credited with recognizing the condition and his name given to it (Ductus Botalli) but he has no claim to it. Harvey in 1628 recognized the purpose of the Ductus. Gibson[128] in 1898 described the murmur associated with it. Seammon and Edgar Norris[350] reported on the time of closure of the ductus and inter auricular septum in 1918. John C. Munro[282] in 1907 suggested and described a technique for ligation but never performed it. When Dr. Elliot Cutler[72] was in Minneapolis to give the Dr. E. Starr Judd lecture, "Total Thyroidectomy for Cardiac Disease," at the University of Minnesota in February, 1937, he was asked by George Farr and Arthur C. Kerkhof to see a woman who had a persistent ductus and decide if there was not something to be done for the condition. He said "not at this time, but send her down and we will see if something may not be done." The patient, a young woman, refused to go to Boston and nothing was done. John W. Strieder,[143] Graybeil and Boyer in 1937, attempted to ligate a ductus unsuccessfully, the patient dying on the fourth day with the ductus still patent. Robert Gross[146] and Hubbard of Boston carried out the world's first successful ligation in 1938. J. Jones, S. Dolley and Lewis Bulloch[190] in 1939-40 reported on a series. Jones[190] stated that for a full year before Gross' first case he had been trying to obtain permission to operate upon such a patient without success. Bruns and Stephen attempted to ligate a ductus but ligated only some fibrous tissue. Tourof and Vessell in 1940 successfully ligated the ductus in a patient with bacterial endocarditis. Clarence Crafoord[66] performed his first ligation of patent ductus in 1942. M. Shapiro[368] and Ancel Keys of Minneapolis in 1943 reviewed the course of patients with an unoperated ductus arteriosus and the prognosis from it. Clagett, Kirklin, Ellis and Cody[59] reported upon 223 patients operated upon at the Mayo Clinic between January 1, 1940 and December 31, 1953. Krovetz and Warden[221] in 1958 reported on 515 cases from the University of Minnesota Hospital from 1939-1958.

On the Minnesota scene the first patent ductus operation apparently was done by Wangensteen[420] in 1939 and with Varco and Baranofsky reported on 76 cases emphasizing the importance of divi-

sion of the duct over ligation. The first operation at the Mayo Clinic was in 1940.

From the local private hospitals I did my first patent ductus operation at Swedish Hospital[207] in 1943, ligating the ductus in a young woman with bacterial endocarditis, left pleural effusion, three pulmonary infarcts and positive blood culture. She recovered with only a little sulfa drug and is alive and healthy to date. We continued to do a considerable volume of this work for Shapiro and others in Minneapolis General Hospital, St. Mary's, Abbott, and Northwestern Hospitals, until September, 1946, when Tague Chisholm[54] joined O. S. Wyatt in pediatric surgery. He had been trained in cardiovascular surgery by Robert Gross in Boston. Working together for a number of years, this work continued in various hospitals doing coarctations, Blalocks, et cetera, and in 1947, a division of a double aortic arch at Abbott Hospital.[208] This was believed to be the first in the state. The first operation for patent ductus arteriosus at the Head of the Lakes was done by Josiah Fuller[118] in 1953. Subsequently Jensen, Schmidt et al.[185] continued this type of work in Minneapolis, then going on to other cardiac surgery.

Coronary Artery Disease

Beck[23] of Cleveland was the first to attempt to obtain additional blood supply to the myocardium damaged by coronary disease creating adhesions to the pericardium by abrasion, by talc insufflation and later in 1935[22] by suture of a pedicle pectoral muscle flap onto the myocardium. L. O'Shaughnessy[298] of England in 1936 used a pedicle of omentum brought up through the diaphragm as a better vascular supply. Lenzius[236] in 1937 excised the pericardium and attached the lung to the myocardium. Fauteux[105] in 1940 ligated the vena magna cordis with the same idea in mind. Arthur Vineberg[407] of Montreal beginning in 1946 and in a continuing series of studies and reports has been a staunch supporter of internal mammary transplants to the myocardium to create additional blood supply to the injured myocardium and has demonstrated persisting anastomotic channels by injection techniques. Many modifications have followed. Some surgical groups have become enthusiastic, others disappointed. Ripstein[329] in 1948 stated that there was no lasting benefit from all types of procedures. An editorial[93] in the *New England Journal of Medicine* in August, 1966, was skeptical. Relief of anginal pain has been recorded frequently. On the local scene Baranofsky[17] and Sparafka from Ancker Hospital in 1954 used defunctionalized jejunal transplants to add blood supply. Ferlic,[107] Quattlebaum and C. Walton Lillehei in 1966 used an arterialized vein graft from the left subclavian artery for this purpose.

Vineberg[408] more recently added another technique involving the removal of the epicardium and the covering of the adjacent aorta, then wrapping the heart with a free omental graft. Sufficient time has not elapsed to evaluate this procedure. Recently another suggestion for increasing myocardial blood supply by multiple ventricular puncture through the damaged area with a #19 needle to encourage new vascular channels has been reported by Khazei et al.[202] and Sen et al. Pifarre[313] et al. in September 1969 deny any clinical or experimental evidence to support its use.

The recent article by Bloomer et al.[34] on the use of the splenic artery for myocardial revascularization is worthy of note.

An analysis of the effects of mammary implantation by Mantini,[259] Tanaka and Lillehei has recently appeared. The recent favorable report of Urschel,[403] Paulson et al. and their discussants on the use of "Aorta to Coronary Artery Vein Bypass Grafts for Coronary Artery Occlusive Diseases" will be followed with great interest.

Cardiac Surgery

Mitral Stenosis

Mitral stenosis, that crippler and killer of young people, had long resisted all efforts at medical treatment. Could surgery do any better? Cushing, Carrel[51] and others had tried experimentally to produce and surgically relieve cardiac valve lesions without too much success. Elliott Cutler[71] of Boston in 1923 using a cardiovalvulotome incised a stenotic valve in a four and one-half year old girl who survived, living four and one-half years before dying from progressive heart disease. This patient, however, was the only survivor of six so treated.

Duff Allen[6] and Evarts Graham of St. Louis in 1923, through a ventricular approach with their cardioscope, attempted to cut the mitral valve but the patient died on the table under anesthesia. Souttar[378] of England in 1925 dilated a mitral valve with his finger introduced through the left

atrial appendage for the second successful case. Charles Bailey[15] on November 14, 1945, using a hooded knife along his finger through the auricular appendage, incised a stenotic valve but the patient died of hemorrhage. After three more failures on June 10, 1948 he successfully incised the commissure in a 24-year-old woman who survived. After failing with a valvulotome in 1947, Dwight Harken[152] of Boston on June 16, 1948 successfully excised a portion of the anterior commissure. By 1950 he had two successes in five attempts. He came to favor finger fracture while Bailey favored the knife. Brock of England[42] successfully used finger fracture and by 1951 had done 47 cases, losing seven of the first twenty. Charles Dubost[90] of Paris in 1953 used a transatrial dilator successfully and by 1962 reported a 2% mortality in 965 valvulotomics. Andrew Logan[251] of Edinburgh used a trans-ventricular mechanical dilator in 1955 with success.

The first successful open operation for acquired mitral disease in the world was done in 1956 by C. Walton Lillehei[244] at the University of Minnesota Hospital. A similar operation was done later that year by K. A. Merendino,[272] formerly of the University of Minnesota, now at the University of Washington.

V. L. Gott[135] inserted the first successful prosthesis for mitral insufficiency at the University in 1957. Starr[383] in 1961 introduced the ball valve prosthesis with six survivors in eight patients. The Starr-Edwards modification followed and later valves by Barnard, Hufnagle, Conrad, Alvarez, Diaz, Cross, Jones and Kay. Aortic homografts were also used. The first closed mitral commissurotomy at the Mayo Clinic was done in 1951.[99] Their first open heart operation on the mitral valve was carried out in 1955. The first valve replacement was done in 1960. Few were done to 1962.

A complete record of the Mayo Clinic experience with surgery for mitral disease by the team of Kirklin, Ellis, McGoon and Wallace has appeared in Ellis' excellent book, "Surgery for Acquired Mitral Valve Disease,"[99] published in 1967.

Heart Pump

The idea of a mechanical heart pump is far from new. Dale and Schuster[73] of London in 1928 constructed a machine to pump the blood but provided no mechanism to provide oxygenation or carbon dioxide removal. Jongbloed[192] in 1948 produced a machine for both circulation and oxygenation of the blood but did not use it. Melrose[270] of London in 1949 started a machine but did not complete it until 1957. Gibbon,[127] Miller and Fineberg through International Business Machine in 1949 produced a complete machine and with it in May, 1953, were credited with the first successful open heart operation, repairing an interatrial septal defect.[127]

Dennis and Varco are reported to have done the first open heart operation with cardiopulmonary bypass in 1950. F. John Lewis and Varco[404] did their first open heart operation under profound hypothermia in 1952. Dennis[82] and Varco on April 5, 1951 attempted to close an interventricular septal defect by open operation with a pump oxygenator but the patient succumbed on the table. The first successful open heart closure of an interventricular septal defect under cross circulation was carried out on a ten-month-old infant on March 26, 1954 by Lillehei,[243] Varco, Warden and Cohen. Lillehei[243] on September 1, 1954 did the world's first complete repair of the Tetrology of Fallot under human cross circulation. He had on August 6, 1954 carried out the world's first repair of an atrioventricular canal under cross circulation. Lillehei and Varco on May 13, 1955 did the first successful closure of an interventricular septal defect under cardiopulmonary bypass using a bubble oxygenator. Lillehei on January 30, 1957 placed the first myocardial electrode for complete heart block. He later on October 31, 1958 did the first prosthetic aortic cusp replacement for aortic stenosis.

F. D.. Dodrill[86] of Detroit with the help of General Motors engineers in 1953 produced a very efficient pump which would by-pass one-half of the circulation. The Swedish team of Bjork[31] and Crafoord on March 20, 1953 using a pump oxygenator performed the second successful open heart procedure. John Kirklin et al. of the Mayo Clinic, using the improved Mayo Clinic model of the Gibbon-IBM machine, successfully closed a septal defect for the third such case in a five and a half hour operation with 40 minutes of open heart surgery.

E. Dennis[82] et al. in the spring of 1951 developed a simple and cheap heart pump which they

subsequently used. Following the suggestion of Morley Cohen,[243] Gilbert S. Campbell[244] carried out on over a hundred dogs the technique of using another animal lung to oxygenate the blood (cross circulation) and found it feasible. Drs. Varco and C. W. Lillehei[222] on March 23, 1955 successfully operated upon a 13-year-old boy, closing three traumatic holes in the heart using a dog's lung for an oxygenator.

For a time the University Hospital used human beings for cross circulation but this was discontinued as pump oxygenators were improved and became available. By January , 1956, 97 patients had been operated on at the[376] University of Minnesota Hospital and 38 at the Mayo Clinic. The work continues at an accelerated pace.

Cardiac Surgery in Minnesota

Cardiac surgery apparently was initiated in Minnesota by Drs. F. C. Mann,[258] J. Priestley, Markowitz and Yater in 1930 with "Transplantation of the Intact Mammalian Heart" the report of a series of homotransplants to the cervical region of dogs, presented to the Mayo Clinic Staff Meeting of April 22, 1931.

Thoracic Surgery which at first developed slowly from crude beginnings has in recent years blossomed suddenly along some lines. The most spectacular has been in the field of open heart operations and organ transplants. The extensive experimental laboratories of the University of Minnesota, the Mayo Clinic Institute and later the U. S. Veterans Facility have developed a large number of individuals, techniques and procedures which have made many of these operations possible. From the faculties and graduates of these facilities have come a number of the outstanding cardiovascular surgeons of the world. Among those who have been exported to top positions around this country and the world have been: John W. Kirklin, C. Walton Lillehei, Alvin Merendino, Clarence Dennis, Bernard Zimmerman, John Paine, F. John Lewis, Morley Cohen, Ivan Baranofsky, Herbert E. Warden, Richard Dewall, Vincent Gott, Fletcher Miller and others. It is worthy of note that Christian Barnard, Norman Shumway, C. Walton Lillehei, C. Cabrol and D. Lepley were trained at the University of Minnesota. A number of Dr. E. Zebrini's associates were also Minnesota-trained.

Thoracic surgery, more particularly the cardiac and transplant type, have ceased to be a lone surgeon's job. It has become a team effort not only from the diagnostic standpoint but very much so from the surgical. The original teams for open heart surgery involved at least fifteen individuals and two or three cases per week were maximum, even in the large surgical clinics. Now with smaller teams involved, it is not unusual to have several cases scheduled per day. The transplant procedures require even larger groups. A recent multiple transplant of heart, lung and both kidneys by DeBakey et al. at Houston involved some 70 members of the operating teams.

Cardiac surgery was introduced to St. Paul at Ancker Hospital by Merendino and Baranofsky who carried on this work from 1949-54. Later Baranofsky started transauricular procedures for mitral stenosis and transventricular operations for aortic stenosis. Coarctation and Blalock operations followed. At the private hospitals, Sam Hunter[179] did his first mitral surgery at Miller Hospital in 1954 and implanted a pacemaker in 1959 at Bethesda. His first open heart surgery for a septal defect was in 1958 at St. Joseph's where he later did valve replacements. The same type of procedures were carried out at Miller in 1960. Cardiovascular surgery has been continued since that time at both places.

The team of Connolly, Culligan and Gannon also have continued vascular and cardiac surgery experimentally and clinically.

Josiah Fuller, a Rochester-trained thoracic surgeon, arrived in Duluth in 1953, where he has done thoracic and vascular surgery since that time. He did his first Patent Ductus May 23, 1953 at St. Mary's Hospital, Duluth, Mitral Commissurotomy March 23, 1954, Congenital Vascular ring May 3, 1956, Pericardiotomy February 26, 1957 and Coarctation July 3, 1957.[118]

Cardiac Transplants

The first human heart transplant in the world was performed on December 3, 1967 at Groote Schuur Hospital in Cape Town, South Africa, by Dr. Christian Barnard et al. on a 53-year-old man, Louis Washkansky, who *died* on December 21 of pneumonia. A team of 29 was used.

By late September, 1968, more than 50 cardiac transplants had been carried out in various clinics throughout the world. The short term mortality in this group of approximately 25 brings the

total mortality for the entire series to near 50%.

The number of transplants increased so rapidly that by December, 1968, over 100 had been reported, and by February, 1969, 114. Additional countries entered the race with operations reported from the Soviet Union, Turkey, Japan, Israel, Poland and West Germany. Additional cities have also been added on this continent with Toronto in Canada, Richmond, Virginia, Chicago, Milwaukee, Cincinnati, Denver and Ann Arbor.

Like most innovations, the advent of cardiac transplantation late in 1967 has added social, moral, ethical, legal and financial and other problems to the medical-hospital scene.

Lung Transplants

Much experimentation has been done on the problem of tissue and organ transplantation. Blood was the first to be used successfully after the problem of matching and agglutination was solved. Bone preserved or of foreign sources, while it did not survive, did remain as a scaffold until new growth took over. Corneal grafts were successful replacing scars and opacities. Skin grafts persisted long enough in burns for emergency use as a temporary covering. Kidney transplants between identical twins were made with a high degree of success. Later when made between close relatives a fair degree of success was accomplished. Intensive studies of rejection phenomena and immune suppressive drugs have increased the chances of success in this field.

The transplantation of the lung has presented problems from the start. Carrel and Guthrie[50] in 1907 were the first to transplant the lung, moving both lungs, the aorta and vena cava from a one-week-old cat to the neck of a large cat. This was not a sterile transfer but the lungs survived for 48 hours uutil infection developed. Dimikhof[81] in 1947 carried out homografts of individual lobes. Staudacher, Bellinazzo and Pulin[382] of Italy did auto and homotransplants of the right lower lobe in dogs. The auto transplants maintained function and anatomical integrity for 12 days. The homotransplants were rejected in eight days. From 1951 to 1956 Lanari, Croxatto and Molin carried out extensive studies with similar results. The first successful autogenous transplant of lungs in animals with long survival was reported by Juvenelle,[195] Citret, Wiles and Stewart in 1951. Portin,[317] Rasmussen, Stewart and Anderson reported followup in 1960. Sim, Yacoubain,[375] Summonian and Sahyoun from the American University of Bierut in 1965 reported one dog surviving 22 months after a staged bilateral reimplantation of the lungs. The ventilatory response to exercise and hypercapnia was essentially normal. Steady improvement of cardiopulmonary function was noted. There was no evidence of vagus nerve regeneration. The animals did not show the pattern of denervated breathing. There was uneven ventilation and persistent hypoxemia at rest. At necropsy there was slight thickening of the alveolar walls.

Studies by Nigro,[290] Reiman, Mork, Frey, Benfield and Wm. E. Adams of Chicago in 1963 on dogs surviving with a reimplanted lung, two of whom survived over one and a half years, by bronchospirometric and pulmonary artery pressure readings showed pulmonary ventilation was only slightly depressed but oxygen uptake was significantly decreased and pulmonary hypertension developed in all animals even with no anastomotic stenosis. The Surgical Forum #XVII[339] of the 52nd Clinical Congress of the American College of Surgeons in 1966 had several reports on various phases of lung transplant. Secrist[366] and Trummer in 1967, testing for Herring Breuer reflex after reimplant of lung, reports that six of 14 dogs showed evidence of some return in seven months while the rest showed none in four to 54 months, suggesting some regeneration of afferent vagal limb. Necrosis of the bronchial suture line and stenosis of the vascular anastomosis occurred not infrequently.

To date, five transplants in humans have been carried out.

Moore et al. have compiled a list of the five total lung transplants, three from the United States and one each from Scotland and Canada. All succumbed in from seven to 28 days. One lobe transplant from Japan had to be removed 18 days later.

The most recent lung transplant patient operated upon at the University of Michigan on September 1, 1969 died on September 4, 1969.

Acknowledgments

The collection of this historical material has involved a review of a vast number of reports from both published and private sources. I am especially grateful to Mrs. Rosemary Perry and Miss Barbara Martin, Mrs.

Bessie Preston and Miss Marqua E. Weathers of the Hennepin County Medical Society Library, to Mary M. Post of the Ramsey County Medical Society Library, to Sister Aquinata and Mary Diemert of St. Mary's Hospital Medical Library, to Helena S. Binder and Mrs. Ina G. Lyngen of Glen Lake State Sanatorium Medical Records, to Rose Nemanich of the Nopeming Sanatorium Record Department, to Goldie Creever, perennial secretary to the Minnesota Academy of Medicine whose search of the meeting programs over the years revealed much information not otherwise available, to Clark W. Nelson, Archivist at the Mayo Clinic, to Drs. Karl Pfuetze, Jesse Douglas, Merv Williams, George Loeb, G. A. Dodds and a host of other physicians who have contributed much information from their experience. Much credit is also due to numerous previous authors from whom I have quoted freely.

I have also drawn freely on my memory of many of the events recorded and my personal acquaintence with many of the individuals mentioned.

Improving Health Care in Minnesota

Reports From

Northlands Regional Medical Program, Inc.

MINNESOTA MEDICINE
Volume 55, December, 1972, Supplement No. 3

Mary Jane Ryan BS, MS, PhD

August 5, 1914—September 7, 1972

Northlands Regional Medical Programs has lost a leader with the death of Dr. Mary Jane Ryan. No person in Minnesota has been more dedicated to the purpose of making scientific information available and accessible to improve medical care.

Her role as Liaison Librarian for NRMP, stimulated Biomedical Libraries in Minnesota to develop an efficient Library System. It is fitting to dedicate this supplement of MINNESOTA MEDICINE to Dr. Ryan in memory of her accomplishments in biomedical library science.

With dedication she supported innovative educational programs and provided leadership in making available the latest biomedical information. She gave freely of her time and talents and stimulated others to do likewise. Her article in this series documents many of her recent accomplishments.

Dr. Ryan was an enthusiastic example of the concept of lifetime learning. After graduating from the College of St. Catherine in 1937 she returned repeatedly to educational institutions to improve her knowledge. She was granted an MS degree from the University of Southern California in 1955 and a PhD in Educational Psychology from the same institution in 1967. During her career she served in ten different educational institutions in South Dakota, New York, California, Wisconsin and Minnesota.

The quantity of her life was not great, but the quality will live on as a memorable inspiration for those of us who knew her so well.

Winston R. Miller, M.D.
Director
Northlands Regional Medical Programs

This publication is dedicated to the memory of Mary Jane Ryan, PhD, Liaison Librarian of NRMP, who passed away on September 7, 1972

A Five-Year Perspective of NRMP

WINSTON R. MILLER, M.D.

Like society as a whole, the health care system is changing. NRMP acts to stimulate these changes in a positive way. Of necessity, the program itself has also changed. Continuing effectiveness in an RMP requires inherent flexibility—the capacity to change and influence change in new ways as new and important issues come into prominence.

The Categorical Disease Phase

Evolving from President Johnson's National Commission Report entitled "A National Program to Conquer Heart Disease, Cancer and Sroke," initial emphasis was on the three categories of disease which cause seventy percent of all deaths. Although the program stirred up controversy, the almost altruistic principles in the RMP law were virtually irrefutable: making the latest scientific advances available to all people; improved cooperative arrangements among all providers of health care services; local authority and administration; a federal-private partnership; no interference with existing methods of practice or payment; incentive awards to stimulate improvement; and improved continuing education for health care professionals. The emphasis on the principal causes of death and disability repeated the time-honored concern of all human societies.

In 1965 a social revolution in America had already started; the accepted socio-political proclamation of "Optimum Health Care as a Human Right" propelled the health care system into the forefront of the social change process. The significance can hardly be overemphasized. The Declaration of Independence proclaiming "life, liberty and the pursuit of happiness" as fundamental human rights has dominated our society since its adoption. Adding optimum health care to this social premise virtually forces major social revisions.

Northlands Regional Medical Program has been supported by HEW Grants 5 GO3 RM-00021. Opinions represent views of the author and do not constitute endorsement by HEW or NRMP.

Dr. Miller is Program Director, NRMP, Inc.

The new system of Regional Medical Programs created high hopes for rapid accomplishment. In fact, the lack of rapidly accelerating momentum nearly caused its demise in 1970 and 1971. Since mid-1971 accomplishments have increased significantly, and this unique federal-private partnership organization has received wide recognition.

Like most RMP's, NRMP started with categorical emphasis, and placed priorities on continuing educational programs for providers of health care services.[1] Although controversy existed as to who would get how much money to do what, the goal of the program was fairly simple. It was to develop optimum health care for patients with categorical diseases, utilizing mechanisms involving new cooperative arrangements and new programs of continuing education.

Change to Broader Goals

The categorical disease focus was short-lived. In less than two years the leaders of NRMP recognized that this new program was really directed at change in the health care system as a whole. Any program which would have a significant effect on the diseases which cause seventy percent of all deaths must address itself to problems in three broad areas of concern: (1) How to produce more effective programs of continuing and patient education; (2) How to correct the shortage and maldistribution of health manpower; (3) How to develop more effective delivery of health care services.

In November, 1968, the Board of Trustees adopted the broad goal of equal and optimum health care services for all of the people in Minnesota. The program staff was directed to conduct or get others to conduct studies to provide better definition of the many unmet needs. Incentive funding of demonstration projects was directed toward the "seed money concept" of stimulating constructive and long-lasting changes. Application of the principles of applied research changed program design from simple subsidization of good activities to prototype studies or demonstrations

for innovative improvements in the health care system.

Education, Manpower and Health Services Development Committees developed policy statements which outlined goals and objectives for the program. These three committees carried responsibilities in planning specific activities, reviewing all applications and management of funded studies and demonstration projects. The intent was to develop a mechanism whereby all activities would fit together in a rationally organized system and respond to specific goals and policies. This philosophy has influenced all planning studies, feasibility studies and demonstration projects.

The change in program design away from the categorical emphasis caused some chagrin among personnel and institutions specializing in categorical diseases. However those working on categorical staff or project activities continued and completed their commitments, while new activities were being undertaken with broader horizons. The planning and feasibility studies conducted by the NRMP staff are shown in Table 1. Table 2 lists all extramural projects conducted between 1968 and 1971. The articles in this supplement of MINNESOTA MEDICINE include reports on seven projects which have now been completed or nearly completed.

Change to a More Structured Approach

In 1971 NRMP embarked on a new methodology of program design. It consisted of two components: (1) detailed job descriptions and planned activities for all members of the employed staff, (2) specific contract offerings for all extramural project applications.

Deriving the basic idea from informal discussions at national meetings, NRMP pioneered in extensive development of the method. Successful implementation evolved from several facts and convictions:

1. Specific planning would facilitate a more structured and integrated program.
2. Committees of the Regional Advisory Group had developed a clearer sense of direction for priority needs.
3. Management of contracts could be more structured than management of project grants, making coordination and performance responsibility more rational and acceptable.
4. The principal areas of need lay in improved primary and secondary health care services, and the "experts" in these spheres were more often outside than inside the medical centers.
5. Small contract offerings would facilitate participation by many more institutions, thus increasing program involvement.
6. Anticipated funding was limited, and more activities could be supported with specific offerings and small total budgets.
7. Regional Medical Programs had gained momentum slowly, and short-term accomplishments were needed.
8. Smaller institutions could handle small projects better than large ones, and might be expected to contribute proportionately more of their own resources.

Program Staff Activities

Job specifications for the 16.4 (full-time equivalent) members of the professional staff and 12.7 members of the secretarial and clerical staff were divided into six subdivisions: (1) Program direction and administration; (2) Project development, review and management; (3) Professional consultation, community relations and liaison; (4) Planning studies and inventories; (5) Feasibility studies; (6) Central regional services.

In 1972, program direction and administration consumes eight percent of the budget, while consultation, community relations and liaison activities use 7.4 percent. Professional staff personnel are directed to help to strengthen cooperative programs among health care personnel and institutions throughout the state. In the past year they traveled over 100,000 miles within the state carrying out their multiple responsibilities.

Planning and Feasibility studies consume 18 percent of the current budget. These studies document unmet needs, analyze attitudes toward proposed constructive changes, inventory resources, introduce innovations, and stimulate regional and subregional network development. The final reports of these studies are circulated widely throughout the state in a deliberate attempt to produce maximum impact. Many of these studies have been completed; some have been published in the medical literature,[2-9] and some are still in process. Although NRMP cannot document the impact of planning and feasibility studies quantitatively, many of the benefits are known. Health planning endeavors throughout the state have used these reports as background resources for their efforts; the legislature has used the contained information for passage of new legislation; many organizations have used the information for development of innovative health care programs; and many of the reports have been accepted as the latest and best information available.

Communication and public relations activities have helped to promote widespread understanding and appreciation of the need for stronger cooperative linkages. The regionalization movement has been publicized by a newsletter, "Northlands News" to a mailing list of 11,000; newspaper articles totaling 4000 inches in 1971; exhibits at all major meetings of health-related organizations; and speeches by professional staff members at many local and national meetings.

The need for an unbiased, multidisciplinary staff of "experts" in the health care field has been reinforced lately by fulfillment of five outside requests for specific evaluation and development studies. One of these, supported by a grant from the Hill Family Foundation, developed consensus recommendations for new experimental projects to improve the delivery of health care services to isolated Indian and white communities in the sparsely settled areas of northern Minnesota. The problem of optimum services for these isolated

communities is complex and difficult, but Minnesota has resources which should be able to grapple with such challenges.

Specific Contract or Project Offerings

Abstracts of 29 specific contract offerings were widely circulated in 1971 to solicit extramural activities which would conform to priority needs.

The activities proposed in the "Contract Offering Prospecti" were readily understood and accepted throughout the state. In the competitive review process, 43 applications from 28 different organizations were approved and ranked numerically in order of priority. Additional federal funding permitted activation of the 29 contracts listed in Table 3.

When it became known that 66 applications had been received in response to the contract offerings, other RMP's adopted the new method. Recognizing that the method represented a new research and development approach for RMP, the national RMPS office recently initiated a nationwide study to evaluate its relative advantages and disadvantages. Desirable attributes include a more structured program design, greater management potential, increased program flexibility, and more widespread involvement in the research and development effort.

NRMP is now conducting the review process for 1973 activities; 24 project offerings were circulated widely; and 69 applications were received

by the July 17 deadline.

Developmental Fund Activities

A new opportunity was provided to NRMP with a "Developmental Fund Award" of $127,000 in 1972. This block-grant-type fund will support small short term studies and demonstrations during the fiscal year. The principle is to fund relatively small projects under the sole authority of the local review mechanism without the rather long delay period needed for the combined local and national review processes. The eleven developmental fund projects initiated as of this writing are shown in Table 4.

Network Development

Many program activities are directed at state or local network development. This kind of regionalization is based on the premise that cooperative networks offer the best solutions to some of the health care problems.

Medical Audit for Continuing Medical Education

A network of coordinated medical audit programs in community hospitals is being developed with cumulative participation of five additional hospitals each year.[2] Details of this activity are described by Dr. William R. Fifer* in a separate article in this series. The success of this program has attracted national recognition. Local medical leaders have been trained to lead their medical staffs in conducting medical audits of actual patient care performance. Continuing education programs are developed according to demonstrated needs, and follow-up audits determine improvement in performance. A new annual Minnesota Hospital Medical Staff Conference has been oversubscribed months ahead of time for the second consecutive year.

Regional Biomedical Library Network

With cooperation and assistance from the two medical center libraries, NRMP has led in development of a system making a full range of library information resources available and accessible throughout the state.[3,4] Details are presented by Dr. Mary Jane Ryan† in a separate article of this series. Components of this development include:

1. Loans of four sample core libraries to any health care institution in the state.
2. Workshops for library supervisors held in multiple areas.
3. Improved functional interrelationships with center libraries.
4. A reference book of all biomedical holdings at the two medical center libraries provided for all other libraries.
5. Library reference services as a part of the new toll-free Minnesota Medical Information Service Center.
6. Easy accessibility to the new national au-

tomated literature search known as MEDLINE.

7. Assistance in obtaining National Library of Medicine grants to upgrade small biomedical libraries.

Rehabilitation Services

The development of a regional network for rehabilitation services promises to strengthen these services throughout the state. Studies of the distribution of services and facilities helped to document the need for network development, and the three rehabilitation centers at the Mayo Clinic, the Kenny Institute and the University have each developed new outreach relationships. Rehabilitation facilities in other parts of the state are also developing stronger linkages with peripheral institutions nearby. Several applications for the 1973 NRMP program seek to extend this network development.

Medical Center Outreach

NRMP has assisted or participated in development of several new outreach programs by Mayo Institutions: regional laboratory services; consultation services; rehabilitation services; short-term residencies; and a satellite clinic in a no-doctor town (The Plainview Health Care Facility).

At the University similar activities include new continuing education courses; consultation services; rehabilitation services; several programs for training new manpower disciplines; and Area Health Center development.

New outreach activities have recently been proposed from several secondary level medical centers—the St. Louis Park Medical Center, the Minneapolis Medical Center, the St. Cloud Hospital, and the Polinsky Rehabilitation Center in Duluth.

Area Health Education Systems

A recent supplemental award will enable NRMP to support and coordinate planning and development of eight community based Health Education Programs covering the state, with back-up support from the two medical centers. The purposes are: (1) Cooperative development of health manpower education programs geared to community needs; (2) Continuing education for health care personnel at the local level; (3) Patient and public education at the local level.

Emergency Medical Service System

Another supplemental award to NRMP will enable the Emergency Medical Services Unit of the State Department of Health to plan and develop a statewide system of comprehensive emergency medical care services. This system is intended to include: (1) Modern ambulances with well-trained attendants; (2) State-wide shortwave communications system; (3) Area and Regional Emergency Medical Care Centers staffed with specially trained personnel; (4) Emergency Medical Care Physicians with shortwave communication equipment.

End-Stage Kidney Disease System

National experts have publicized plans for multiple kidney disease networks in all parts of the country. As in many other fields, Minnesota has already made great progress in this development. Plans are now underway for expansion of this program to a multistate system which will provide optimum services for all patients in Minnesota, North Dakota and South Dakota.

Discussion

It has been difficult for many people to understand Regional Medical Programs—what they are, what their mission is, and how they try to accomplish their mission. Examples of difficult concepts are: federal-private partnership, catalytic activities to stimulate cooperative and construction change, regionalization and subregionalization, applied research and development, and health care systems development. The contract and project offering methodology has helped greatly to increase understanding.

NRMP provides funds for activities by many organizations, but it is not primarily a funding agency—all funded projects and contracts become integral components of the program, responding cooperatively toward broad regional goals. Although it does not support basic research, NRMP stimulates and supports applied research and development—the goal is improved delivery of health care *services*.

NRMP seeks to carry out its mission according to rational scientific principles. Rational solution for problems requires scientific analysis of needs, mobilization of resources necessary to meet those needs and demonstration projects providing convincing evidence of significant improvements.

It is of great importance that support be continued for unbiased research and development activities like those of RMP, to help insure maintenance of quality during this period of rapid changes in the health care system. The best talents in the country are needed to work on the problem

areas. They should not be thwarted in their efforts by any of the power blocks with vested interests (whether these be the federal government; syndicates of insurance companies, hospitals, health care corporations, medical centers or medical foundations; or the exclusive power actions of professional organizations). Applied research needs the same administrative milieu as fundamental research—one which permits a maximum of intellectual challenge, application of the scientific method, prestige and recognition rewards for accomplishment, and a minimum of rigid direction and management.

What is the future for RMP or RMP-like programs? In the immediate future RMP will probably play an increasing role in helping to maintain quality and develop new solutions to pressing problems. RMP is unique in that it has the potential for exerting considerable influence, without restrictive control by any level of government or by any of the power blocks in the health care system. It will be called upon increasingly to advance the science of applied research and development, to promote the fields of health care economics and health care systems development, and to use its multidiscipline staffs to provide evaluation studies and consultations for other organizations.

It seems probable that health care authorities or commissions will be developed to provide some kind of regulation of the health care industry. When this occurs, there will be jurisdictional changes in many publicly supported programs, and RMP will undoubtedly be one of them. Hopefully the desirable attributes described above will be preserved; it is believed that they will if our society continues to recognize the value of voluntary intellectual commitment and unbiased research and development.

A System of Continuing Medical Education

Based on Medical Audit

WILLIAM R. FIFER, M.D.

THERE ARE 5,000 physicians in Minnesota who are in clinical practice. As individuals they are solely responsible for maintenance of their clinical competence. As student, intern or resident, the physician devoted all of his attention to learning. Now his principal activity is patient care. To do this job well, he must constantly update his medical knowledge. Due to rapid infusion of new information from biomedical research, a physician's knowledge store has a half life of less than ten years. A physician who fell asleep like Rip Van Winkle ten years ago would not know about Rhogam, about ethambutol, about staging procedures for Hodgkin's Disease, about coronary bypass surgery, about amniocentesis, etc. Regional Medical Programs were created to close the gap between the ivory tower and the practicing physician. Northland Regional Medical Program, like all Regional Medical Programs, has emphasized continuing medical education (CME) as the principal means to upgrade the quality of medical care. The basic question in CME is "Who needs to know what?" and we have begun to implement a statewide system of continuing medical education based on the determination of knowledge needs by review of actual patient care, medical audit.

Modes of Continuing Medical Education

How do physicians continue their medical education? First, patient care experiences are a vital learning resource. Second, consultations and daily contact with other physicians contribute greatly. Third, hospital staff meetings, medical and specialty society meetings provide new information. Fourth, continuation courses are provided in abundance. Fifth, reading medical books and journals continues to educate. Finally, innovative learning methods such as medical television, tape cassettes and videotapes are available.

Although there is no organization of this series of random experiences, there is certainly more continuing medical education offered than any of us can use.

Learning Theory

Educators tell us that retention of knowledge depends on its utility and its relevance.

Educators also tell us that there is a "teachable moment" at which time we are maximally receptive to new knowledge. In clinical medicine we reach the teachable moment when we are confronted with a clinical problem. We then call a consultant, go to the library, or in other ways acquire a *needed* piece of information to solve the problem of John Smith. We will remember the problem and our solution long after we have forgotten the source of our information.

Identification of Continuing Medical Education Needs

Given an almost unlimited number of opportunities to learn, how does a physician decide what to choose? When we divide medical practice into *what we know* (knowledge) and *what we do* (medical care), the question becomes: What is it we need to know in the context of what we do? There are three currently popular means of determining needs: *self-assessment tests, individual practice profiles, and medical audit.*

Self-assessment examinations are now offered by specialty societies in many fields. The internal medicine examination is called MKSAP-II, and is sponsored by the American College of Physicians. It is divided into nine subject areas and may be taken either as a closed or open book test. The examinee, after taking this test, learns two things: (1) what he *knows* of internal medicine divided into nine categories, and (2) how he compares with his peers.

Individual practice profiles measure not what a physician *knows* but what he *does*. Developed by

Feasibility Study by the University of Minnesota Component of the Program Staff of NRMP, Inc., supported by HEW grant #5 GO3 RM-00021. The opinions presented do not constitute endorsement by HEW or NRMP, Inc.

Dr. Fifer is a Professor, Department of Medicine, University of Minnesota Medical School, and Associate Director, Northlands Regional Medical Program.

the University of Wisconsin Medical School, this technique is as follows: A physician carries a tape recorder with him for several days, recording information for each hospital visit, office visit, and telephone call. The tape is then analyzed and a report describing his *practice profile* is sent to the physician. Along with the profile, the physician receives an educational prescription which says "inasmuch as you do *these things,* you need to *know* these things." The University then lists those courses, meetings, lectures, etc., most pertinent to the knowledge requirements defined by his practice analysis.

Medical Audit is defined as *a system of continuing medical education based on the evaluation of the quality of patient care as reflected in medical records.* We feel that medical audit is superior to either self-assessment exams or practice profiles in that it demonstrates the application of medical knowledge to patient care situations.

The Minnesota Medical Audit Program is funded by Northlands Regional Medical Program, and promoted by the University of Minnesota program staff. Described as a "Feasibility Study of Medical Audit," the program began April 1, 1971 in five Minnesota community hospitals (Austin, Fergus Falls, Hibbing, Virginia and Worthington). These hospitals were selected because of their diverse geographic distribution and because they were relatively "closed systems" in which the medical staff-hospital relationship was well established. Their sizes range from 64 to 185 beds, and their medical staffs contain from 17 to 40 physicians. Altogether, they comprise 142 physicians and 663 acute beds.

To qualify for participation in the study, we asked each hospital to meet four conditions: (1) approval of the program by the governing board, administration and medical staff, (2) medical records information retrieval capability (four of our first five hospitals have PAS/MAP), (3) willingness to create an education budget to respond to identified educational needs. and (4) apointment by the medical staff of one of its leaders to work 20 percent time as director of continuing medical education (DCME). Northlands Regional Medical Program provided the funds for the DCME position. It was understood by the hospitals that NRMP financial support would be withdrawn at the end of the one-year study period. We felt that one year was adequate to determine the value of the medical audit program in terms of improved patient care. Thus, we hoped to "set tops spinning" at a rate of five per year, and hoped they would keep on spinning after our seed money support was withdrawn. At present, four of the five will continue the program on their own, and we have begun working with four new hospitals. [Albert Lea, Fairview (downtown), Methodist (St. Louis Park) and St. Cloud] in the second year of the program which began April 1, 1972.

Methods

To implement our program, we have worked directly with the affiliated hospitals to assist their DCME's and medical staffs to establish a system of medical audit. In addition, we have conducted monthly medical audit workshops, an annual statewide hospital staff conference, and an annual continuation course on medical audit at the University of Minnesota. To establish an audit program in a hospital, we found it necessary to *teach the process* to the medical staff.

The *process of medical audit* involves six steps:

1. *Criteria must be defined* for optimum care of the disease or condition to be studied. If we study patients discharged with a primary diagnosis of diabetes mellitus, we set the recording of funduscopic examination for 95 percent of the patients examined as a criterion.

2. *Actual care must be reviewed* to display existing practice patterns. We may study 100 consecutive admissions for diabetes mellitus and find that 36 percent of the charts have funduscopic examinations recorded.

3. *Ideal vs. actual must be compared* to determine if a gap exists. In our example, the gap is between 36 percent actual performance and 95 percent optimal performance.

4. *Gaps must be translated into educational objectives* to form the basis for a continuing education program. In our example we state the objective in this way: "Following an education program on diabetic retinopathy, 95 percent of the charts of patients discharged with a primary diagnosis of diabetes mellitus will contain a recorded funduscopic examination."

5. *The education program must be implemented.* We may decide on a series of three presentations, one on classification of diabetic retinopathy; one a presentation of fundus photographs and/or clinical experience sessions; and one on photocoagulation techniques with laser beam.

6. *Finally, we must evaluate the program* at an

ppropriate interval. In our example, we study he next 100 consecutive records of patients ischarged with a primary diagnosis of diabetes nd determine the number of recorded funduscopic xaminations. If actual performance remains at 6 percent, our program failed; while if funduscopic exams jumped to 82 percent, we caused a hange in learner behavior.

What are the *requisites* for a hospital staff to erform medical audit? First, they must be *fficiently organized.* The common practice we ncounter is *horizontal* review of care rather than *ertical* (holistic or patient-centered). We have ften recommended a reorganization of medical ommittees with the anchor committee (called the udit or professional activities committee) systematically reviewing profiles of patient care.

Second a medical staff must have a medical ecords department capable of *information retrieval* on demand. If an audit committee of six nen decides to study the management of diabetes nellitus by reviewing all the charts for one year, hey might first decide what basic information hould be recorded on *all* diabetes charts. This nformation can be quickly provided by the nedical record librarian from the computer printuts (PAS/MAP). Then they might select for leeper study a certain group of diabetics which re displayed in groups on the computer printuts. Having decided to look at diabetes either roadly or at a specific problem in diabetes, the committee first sets *pattern criteria* for optimal performance, then goes to the records to see how ctual care measures up to optimal standards. The information they need to review care may be divided into: (1) that which the medical record librarian can get from the PAS/MAP computer printouts (example: percent of funduscopic exams), (2) that which the medical record librarian can find by studying the chart (example: percent of diabetics taught foot care), and (3) that which requires medical judgment and hence review of the record by a physician (example: appropriateness of the surgical therapy of diabetic peripheral vascular insufficiency). In this way, the committee can systematically review the care of diabetics in their hospital to determine what continuing education in diabetes is most appropriate for their medical staff.

In *organizing* medical audit, *only* the medical staff can establish optimal standards. The medical records department prepares the displays of actual care. The medical staff then performs the evaluative step by comparing the optimal with the actual level of care to detect gaps which may be closed by continuing education.

In addition to working with individual hospitals to assist them to institute audit, we have conducted monthly medical audit workshops using a "show and tell" format in which various hospitals present audits. Nurses were included initially, but now have split off into a separate group to develop nursing audits. We accept this split as a temporary expedient, and plan to bring the health team together by focusing on *patient-centered* (vs. professional-centered) and *outcome-oriented* (vs. process-oriented) audits.

In addition to the workshops we sponsored two more formal conferences: The first of these was the First Annual Minnesota Hospital Staff Conference in September, 1971. This two-day invitational conference was attended by management teams made up of trustees, administrators and key medical staff leaders from each of 27 hospitals. The theme of the conference was the quality of medical care in community hospitals. Its objective was to convince trustees that the responsibility for quality was legally theirs, and that they discharged this responsibility through the organized medical staff. We followed this up with a two-day continuation course at the University of Minnesota on the "how to" of medical audit in October, 1971, attended by 63 physicians from hospitals all over the state. We feel these companion efforts have helped to create a broad climate of acceptance of medical audit in Minnesota, and have developed a cadre of physicians capable of leadership.

Results

It is premature to evaluate the success of the first year's effort. We intentionally structured the program loosely to permit great diversity of activity among the participating hospitals. We felt the program would be more likely to succeed if it was their very own rather than a University program in their community. Because each hospital is so different politically and organizationally, the program took different forms at different sites.

Despite operational obstacles, and thanks to dedicated work by the DCME's and small staff committees, the first year's hospitals developed skills in medical audit, learned to develop their own pattern criteria, and learned to formulate education programs for the medical staff in re-

sponse to specific gaps identified by audit. They accomplished dozens of audits despite heavy patient care demands. Education programs were produced and when an outside speaker was employed, he was informed of the educational objective before he spoke to the staff. Time has not yet permitted completion of the audit cycle to see if the education resulted in change of physician behavior by re-audit of the disease or condition. We await these re-audits with great interest.

Subjects dealt with by the first year's hospitals included the use of antibiotics, anemia, diabetes mellitus, myocardial infarction, appendectomy, hypertension, duodenal ulcer, cholangiography, cholecystectomy, the use of tranquillizers, and urinary tract infection. In some instances data were pooled and shared by the hospitals.

Two hospitals, in auditing myocardial infarction, concluded that pacemaker capability was necessary for optimal care. As a result, members of each medical staff returned to the medical centers for training in the use of transvenous pacemakers. Another hospital, after auditing myocardial infarction, decided they needed to know more about serum lipids, and instituted a series of medical staff education sessions designed to improve their diagnosis and therapy of hyperlipidemia.

Audits of diabetes mellitus led one hospital to institute a series of educational programs on recent advances in the therapy of diabetic retinopathy. They selected this topic after discovering that only 34 percent of the patients discharged with a primary diagnosis of diabetes mellitus had their fundi examined. Another hospital concluded, after studying their diabetic care, that they needed to increase the use of other health professionals (nurse and dietitian) in the education of the diabetic patient.

Almost every audit disclosed room for improvement and indicated a specific behavioral change that was desired. The medical staff felt that an educational program would produce the desired result in some cases; in others, they chose a procedural or operational solution.

Discussion

We can generalize about a few things we learned in the first year:

1. Before action occurs, an attitude change must occur. We have seen a general acceptance of the peer review process, and of the concept that the organized medical staff is responsible, *as a group,* for every single patient cared for in the institution.

2. Medical staff organization is a problem. The medical care appraisal function is spread about in many committees and each hospital must solve this problem in its own way. Some redesigned their committee structure, others left the committee structure essentially intact, and reassigned functions. Common to all, however, was the perception of a *need to be organized* to accomplish the job of medical care appraisal.

3. The state of medical records is a problem. Since medical audit requires "the evaluation of medical care *as reflected in medical records,*" the record becomes the key document. If the record is complete, legible and contains a concise discharge summary, the record librarian is able to abstract it for PAS/MAP. The latter step permits another chance for error, however, and we learned that the record abstract was often the weakest link in the information retrieval chain.

4. Definition of optimum criteria by the medical staff is a problem. They are much more inclined to simply "take a look at a subject and see how we're doing," without having first defined standards. The criteria committees often asked for "cookbook" standards developed by "the experts," and had to learn that the educational value of standard setting probably equals that of care evaluation.

In addition to continuation and expansion of hospital-based medical audit, we plan to extend our program activities this year. Beginning April 1, 1972, Northlands Regional Medical Program has funded demonstration projects to extend audit to: (1) the outpatient setting, and (2) the problem-oriented record. These new directions recognize and attempt to correct two limitations of hospital-based medical audit. The first is that hospital-based audit does not apply to the medical care which takes place in ambulatory settings. Three group clinics (East Range Clinic, Virginia; Nicollet Clinic, Minneapolis; and the St. Louis Park Medical Center, St. Louis Park) have been funded to carry out computer-based audits of outpatient care this year, and we look forward to their results with great interest.

Audit of the problem-oriented record attempts to correct a second deficiency of the conventional hospital medical audit—namely that it accepts the diagnosis as given, and is unable to critically study diagnostic process or outcome. By auditing *prob-*

lems rather than *diagnoses,* we can set criteria for and evaluate the care of 100 consecutive admissions for *chest pain* or *headache,* or *jaundice, etc.* This strategy moves us closer to the real world of patient care and offers exciting opportunities for doctors to apply the educational process to their own logic sequence in patient management. Two hospitals (Bethesda Lutheran and Miller in St. Paul) began these demonstration projects on April 1, 1972, and we will be greatly interested in their results.

Summary

Northlands Regional Medical Program has begun to develop a system of continuing medical education based on needs demonstrated by the process of medical audit. This system offers the potential to: (1) increase the *relevance* of continuing medical education by relating it to patient care, (2) provide on-site learning experiences in community hospitals, (3) merge continuing medical education and patient care by making the community hospital a teaching hospital, and (4) above all, improve patient care through continuing medical education.

A Dialogue with Sir William Osler on Postgraduate Education

Critique of a Northlands Regional Medical Program

RUSSELL V. LUCAS, JR., M.D.

IT WAS A TYPICAL August night in Minnesota, sultry, wind gusting, sheets of rain assaulting my window and distorting the lights occasionally appearing in the inky black. I had labored some time, in vain, to prepare an evaluation of "A pilot project in postgraduate education in pediatric cardiology and neonatology." My friend Win Miller was acting like an editor. All creativity had escaped. I gazed vacantly out the window.

A rich warm voice projected from the shadows. "I had an interest in postgraduate education, perhaps I can help." I turned to see a tall slender man of impressive bearing. His black hair was beginning to recede, a full moustache adorned his upper lip, and his black piercing eyes were set off by full brows and an acquiline nose. Despite his appearance, he seemed a warm and understanding man.

Sir William Osler.

During the discussion that ensued, I had the wits to take some notes which I used later in recording our conversation.

Introduction

Sir William:

"Before we get down to your problem, what is the state of medicine these days?"

Author:

"Not too well if we take at face value what is described by the press, the 'lay medical journals', and politicians of all callings. They lament the widening gap between medical capability and medical performance. We hear, for example, that ⅓ of recent medical school graduates fail to continue postgraduate training once they start practice.[1] Estimates suggest that 20-70% of all M.D.'s fail to participate significantly in postgraduate educational endeavors."[2]

Sir William:

"Things haven't changed much then! Let me recall what I thought about that at the turn of the century. Bear with me if I falter occasionally; you're aware that we don't remember what we write.*

> If the License to practice meant the completion of his education, how sad it would be for the practitioner, how distressing to his patient.[3]

I was moved to sadness by a physician of my acquaintance who

> crawled up on the bank and the stream left him there, but he did not know it.[3]

On the other hand, the country doctor who maintained his skills and utilized his opportunities for postgraduate education filled me with joy."

Author:

"You're implying that the physician, now as then, lacks appropriate motivation for continued learning."

Sir William:

"Some perhaps, but that's not the whole story. What about the professor, the medical school, who are bypassed by the stream of medical knowledge. I used to call that condition 'old fogeyism'.

> Would you know the signs by which, in man or institution, you may recognize old fogeyism? There are three; First a state of blissful happiness and contentment with things as they are; secondly a supreme conviction that the condition of other people and other institutions is one of pitiable inferiority; and thirdly, a fear of change, which not alone perplexes, but appals.[3]

Are these signs of old fogeyism in today's pro-

This report is based on a demonstration project entitled "Pilot Study in Postgraduate Education in Pediatric Cardiology," sponsored by the University of Minnesota. It was a component of Northlands Regional Medical Program, Inc. supported by HEW grant #5 GO3 RM-00021. The opinions presented do not constitute endorsement by NRMP, Inc., or by the Department of Health, Education and Welfare.

Dr. Lucas is Professor of Pediatrics, Dwan Professor of Pediatric Cardiology, University of Minnesota School of Medicine.

*Direct quotes from Sir William's writings are in references. Other comments are poetic license, but reflect the author's understanding of Osler's philosophy.

fessors and medical schools?"

Author:

"Yes, in some the condition is quite advanced."

Sir William:

"Then perhaps faulty postgraduate educational methods play an important role in the failure of physicians to participate in postgraduate educational opportunities."

Author:

"We thought so! In our design of a pilot study in postgraduate education in pediatric cardiology. we started with the assumption that faulty educational methods were a major factor. We believed that our own past efforts and others failed because they:

a. did not identify the needs of the learner-physician;
b. allowed little active participating by the learner-physician;
c. too often provided a mass of unintegrated facts;
d. did little to develop analytical abilities or judgment;
e. did not allow the acquisition of new skills; and
f. were seldom conducted in the physician's natural environment."*

Sir William:

"Well, Well. What's necessary for good postgraduate education then?"

Author:

"We thought the following:

1. The specific needs of the practicing physician must be identified and the curriculum designed to meet them.
2. The practicing physician must actively participate in the learning process.
3. The postgraduate program must be personalized so that differing needs of individual physicians may be met.
4. A significant portion of the program must occur in the physician's local environment.
5. The program should be patient oriented.
6. The program must be conceived as continuing over the professional lifetime of the physician."

Sir William:

"I see. You're trying to switch from a teacher oriented curriculum to one that's oriented toward the physician learner. How did you go about it?"

Author:

"The Northlands Regional Medical Program, a federally funded, regionally directed organization liked the idea, modestly funded us, and helped us define the following goals:

1. Provide immediate postgraduate education in pediatric cardiology throughout Minnesota;
2. Established more effective methods of postgraduate education; and
3. Encourage local physicians to assume a larger role in their postgraduate education."

Sir William:

"You call $30,000 a year modest! I recall when little more than twice that, $70,000, was the total budget for all 11 Canadian medical schools.[4] My apologies! Let's hear how you attacked those worthy goals."

Methods and Results

A. Utilization of the Crippled Children's Service Cardiac Clinic as a focus for Postgraduate Education

Author:

"Through the encouragement and cooperation of Dr. Mildred Norval, arrangements were made to utilize the crippled children's cardiac clinics as foci for postgraduate seminars. In our three year experience, thirty crippled children's cardiac clinics in nine Minnesota communities were utilized. In each of these clinics, 15-75 children with cardiac disease are seen. The clinics are staffed by pediatric cardiologists from the Mayo Clinic, St. Louis Park Medical Clinic and the University of Minnesota. A number of different educational programs were utilized in conjunction with the crippled children's cardiac clinics over the period of the pilot study as follows:

1. Informal lectures.

   An eight session curriculum designed to meet the needs of the practicing physician in the area of pediatric cardiology was formulated and utilized. This gave the visiting pediatric cardiologist guidance for his discourse and eliminated the possibility he would talk about his favorite defect or his current research efforts. The lectures were given during noon lunch breaks at hospital staff meetings, in the early afternoon at the cardiac clinics, in the late afternoon at the cardiac clinics, and at night after dinner and in conjunction with county medical society meetings. The noon and early afternoon sessions were least well attended."

Sir William:

"Perhaps practicing physicians are still busy in their clinics and miss lunch."

*Editor's Note: These several points apply to all phases of medical education!

Author:

"That's right. On the other hand, the late afternoon and evening sessions, though better attended, had a rather high percentage of inattentive physicians."

Sir William:

"Hypoglycemic and sobriety factors, respectively."

Author:

"Our next method was:

2. Patient oriented case discussions after cardiac clinics. These sessions allowed the physician to participate in the examination of a child with congenital cardiac disease and discuss the details of management. In one variation, patients with interesting and common problems were held over and presented to the physicians for their examination and discussion. This was a most valuable exercise if there were a small number of physicians. However, if more than 3 or 4 physicians attended, a great deal of time was wasted while each patient was examined and the sessions lost clarity and direction. For a small number, this type session was a most effective educational device. A second variation, useful for a larger number of physicians was to present the history and physical findings, review Xrays and electrocardiograms of a number of patients. Each case was the basis of discussion, often spirited, of the problems posed to the practitioner."

Sir William:

"That sounds better. The focus is now on the patient."

Author: "Our next approach was:

3. Physician attendance at the crippled children's clinic.

   The practicing physician often visited the cardiac clinic to review the findings and management of a patient he had referred. This provided an opportunity to review thoroughly the physical findings and the natural history of the cardiac disease and its management."

Sir William:

"Now you're getting somewhere! You've rediscovered the perfect medical learning situation, the triangle of student-patient-teacher."

Author:

"This was unquestionably the best learning experience, but it takes one teacher for every student. That's an expensive method."

Sir William:

"Perhaps, but do all your teachers teach? I doubt it. Some won't. Others, who will, aren't asked. This looks like a problem money is not required to solve, but rather harmony and good will in our profession.

> Medical men, particularly in smaller places, live too much apart and do not see enough of each other. In large cities we rub each others angles down and carom off each other without feeling the shock very much . . . as a preventative of such a malady, attendance upon our annual meetings is absolute, as a cure it is specific."[4]

Author:

"Perhaps then, even if some of our pedigogical methods were suboptimal, the fact they encouraged physician dialogue was most important."

Sir William: "Quite so."

Author:

"Sir William, your words about the isolation of physicians brings to mind a totally unexpected result of our educational efforts in the crippled children's clinics. It has to do with:

4. Education of allied health personnel in the Cardiac Clinics. Early in our program, the public health nurses and social workers in the cardiac clinics asked for educational sessions tailored to their needs. They were aware of the many problems faced by the community in providing the optimal environment for children with heart disease. Therefore, community school, hospital and public health nurses, social workers, and school administrators, teachers, and athletic directors were invited to special sessions at the close of the cardiac clinics. Brief explanations of congenital heart disease and rheumatic fever were given followed by a lengthy question and answer period. The discussions centered on the child with heart disease; his habilitation and rehabilitation, special school and activity programs required, his medical, dental and nursing needs, as well as the psychological stress imposed on the children and their families."

Sir William:

"Those are the things we doctors used to take care of."

Author:

"That's true, but most physicians today welcome this help. The major problem, as it is in all human affairs, is meaningful communication. We saw evidence that avenues of communication be-

tween the allied health personnel, parents, community physicians and medical center physicians were unclogged by these shared educational experiences."

Sir William:

"So you had 30 of these educational programs in nine Minnesota communities. How many students?"

Author:

"180 physicians, and 290 nurses and other allied health people."

Sir William:

"May I ask two critical questions. First regarding the scope of the program. I recall that I once said pediatrics was the best specialty, because children's ailments were too diversified to allow much specialization.[5] But pediatric cardiology; isn't that splitting the hair pretty fine?"

Author:

"That we learned. The NRMP people thought so, too."

Sir William:

"Secondly, while the cardiac clinics were in the physician's community, they weren't really in his practice environment.

> About the hospital centers all that is best and highest in the profession of medicine. In it, not in the medical school proper, not in the laboratories, not in the museums, we doctors live and move and have our being."[6]

Author:

"We recognized the validity of both of your critiques. Therefore, in 1970 we embarked upon a program to provide postgraduate education in the care of the sick infant in community hospitals."

B. In-service Training for Nurses and Physicians in Neonatal Intensive Care

Author:

"Several factors favored utilization of infant care as a focus for an in-service educational program for physicians and hospital personnel. These included the recent improvement in definitive care for infants born with serious cardiac defects and other congenital problems, the almost revolutionary improvements in supportive care for infants, the need for the acquisition of new technical skills, and new treatment philosophies in the care of infants. Further, since the infant has a limited response to illness, the techniques of medical care necessary for the infant with serious cardiac disease applied equally well to all who are sick. The goals of our in-service program were to:

1. Impart the knowledge and skills necessary to the recognition of the sick infant.
2. Provide the knowledge and skills necessary for appropriate therapy in the areas of oxygenation, heat control, feeding, acid base and electrolyte balance, treatment of infections, and treatment of congestive cardiac failure.
3. Provide the means to determine when a sick infant requires transfer to a specialized diagnostic and treatment center and the methods of optimal transfer of the infant.

An in-service training program, lasting one-half to one day was given in 21 hospitals. Each program was conducted by a physician and an infant intensive care nurse from the University of Minnesota Hospitals. Preliminary discussion between the visiting team and the community hospital personnel established the specific local situation and problems within the context of the above goals. In the 21 hospitals, 380 nurses, LPN's, and technologists and 45 physicians were served."

Sir William:

"I suppose it is still true that many of the new and specific medical facts and skills are soon obsolete."

Author:

"True enough. Important as these new facts and skills were, a more important consequence of the in-service programs was the establishment of improved communication among nurses, technicians and physicians. We also observed that the University nurse-doctor team improved their understanding of infant care."

Sir William:

"The teacher usually accrues the greater benefit in his encounter with a student."

Author:

"Evidence that improved patient care resulted from these programs can be found in several areas. Changes in nursing and hospital procedures were often instituted during and immediately after the in-service session. Several institutions sent one or more nurses to infant intensive care units for long-term training. Finally, there was a significant increase in the number of sick infants referred to neonatal centers in Minnesota and an equally dramatic improvement in their initial recognition, local care, and transport.

Sir William:

"These programs represent considerable effort. I'd be interested in knowing the participants."

Author:

"The NRMP through funding and by helping us to continuously refine our goals, and evaluate our progress. The Division of Crippled Children's Services, director, and clinic personnel, made the cardiac clinics possible. The Minnesota Chapter of the AMA, the Minnesota Chapter of the Academy of General Practice and the State Board of Health provided approval and support.

The County Medical Societies and the hospital staffs, provided their meeting times and facilities for our programs. The St. Louis Park Clinic, the Mayo Clinic, and the University of Minnesota, provided the teachers pediatric cardiologists and nurses for all the programs."

Discussion and Conclusions

Sir William:

"It would appear you and your colleagues have achieved modest success in reaching your first two goals. You have carried postgraduate education into Minnesota. You also seem to have instituted some improved methods of postgraduate study.

But what have you done to encourage the physician to assume greater responsibility for his education? A physician should return to formal study for several months every few years. During all my tenure at John Hopkins, I held courses for practicing physicians.

> To meet these good earnest students from all parts of the country, some of whom have been in practice fifteen or twenty years, stimulates ones optimism as to the outlook of the profession."[3]

Author:

"We must admit to failure in this regard, Sir William. In three years, only one physician availed himself of this opportunity to return to the University for one or two months, even with a modest stipend provided for study. Perhaps our offering was too specialized. Perhaps we did not "sell" hard enough. It may be physicians don't wish to shoulder the responsibility for their own continuing education. Many it seems, hand over this most important responsibility to others, their societies, their journals, their medical schools."

Sir William:

"A little harsh, don't you think, on both student and teacher? As I once predicted, medicine in the U.S. provides the world's keenest inspiration."[3]

Author:

"Sir William, your life and writings reflect a remarkable sensitivity to the medical needs of your time. This sensitivity to your own era, accounts no doubt for your unusually accurate prescience of our present time. Would you care to predict what lies in store for medicine in the U.S. today?"

Sir William:

"Recall that I've said few men over 40 retain their creativity. It's been a while since I passed that milestone. Moreover, the mark of an old, perhaps wise, man is to know when to quit. However, an old fool seldom can resist the chance for a final word.

First, postgraduate medical education is too important to be left to the professors, or to the societies, or to the journals or to the government. It must be nurtured, like life itself, by each physician. He must accept all the help he can get, searching always for the defects in his knowledge, the faults in his reasoning.

> I would encourage him in a keenly skeptical attitude . . . ever remembering Benjamin Franklin's shrewd remark that 'he is the best doctor who knows the worthlessness of the most medicines.'[7]

Second, all augers well for American medicine as long as it retains the excitement of discontent, the tumultuousness of conflict, the ecstasy of discovery, and the humility of commitment.

Finally, each physician marches to his own drum. Learn the beats of your colleagues, so as to understand them better, and to more fully appreciate your own beat."

A Biomedical Library System for Minnesota

MARY JANE RYAN, PH.D.

BILLIONS HAVE been spent on medical research in this country, leading to a rapid expansion in medical knowledge. Still, the published information based on the research findings remained largely inaccessible to practitioners on the patient care level until more effective methods of retrieving the pertinent information were developed.

The purpose of this paper is to describe achievements to date in the development and extension of a biomedical library system capable of reaching practitioners in every region of Minnesota. The components of this system include: (1) the hospital library; (2) a local library supervisor; (3) library consultant services; (4) extension services from key libraries in Minnesota; (5) access to resources from the National Library of Medicine.

The main goal is to improve, equalize and expedite access to published literature in the health sciences. By linking and sharing the existing library resources at key centers, auxiliary library services become accessible to health professionals in hospitals and other health care institutions in other locations. The implementation of this concept is dependent upon close cooperation between the lending and the borrowing libraries and their parent institutions. In Minnesota there is a long tradition of cooperative arrangements between metropolitan hospital libraries and resource libraries sponsored by the University of Minnesota, the Mayo Clinic and by the Ramsey County, St. Louis County and Hennepin County Medical Societies.

However, health care practitioners outside of Duluth, Rochester and the Twin City areas have had limited access to medical and hospital library services. The priority accepted by Northlands Regional Medical Program is to help interested hospitals located outside metropolitan areas to develop effective library services pertinent to local staff needs.

Feasibility study of the Program Staff of NRMP supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by HEW or NRMP, Inc.

Dr. Ryan was Liaison Librarian, Northlands Regional Medical Program, Inc., St. Paul, Minnesota. Dr. Ryan died September 7, 1972.

The Role of a Hospital Library in a Small Community Hospital

The hospital library and its services should be developed to support the programs of the hospital and to meet the needs of the medical and hospital staff. Centrally located, realistically funded, adequately supervised, it should be available twenty-four hours per day.

A highly selective, relevant library is graphic evidence that a hospital cares about improved patient care. It probably represents the most important single facility for continuing education related to the delivery of optimum health care services.[1] Increased demand for expanded library services is stimulated by staff involvement in medical education, inservice education, field training, clinical staff meetings, accreditation committees, refresher courses, board examinations, peer review, medical audit, program development, community health, research, and preparation of talks and papers.

As the center for on-site information services, the hospital library must also function as the connecting link for interlibrary services from larger resource libraries.

The Hospital Library Committee, composed of physicians, nurses and other allied health professionals, can tailor the library collection and services to local needs, thereby making them truly viable resources.

Developing and Improving the Hospital Library Collection

Hospital libraries in small community hospitals do not need and should not have a large quantity of books and journals. What is needed is a current, basic collection of authoritative, relevant books, journals and reference materials which feature indexes. All major fields related to health care should be represented in the collection.

Paradoxically, one of the most obvious needs in the development and improvement of a hospital library collection is often the most difficult task to perform by local staff members. Discarding outmoded, mediocre, irrelevant material is more

difficult than selecting current, authoritative, pertinent books and journals. To thoroughly weed an existing library, each item should be scrutinized according to valid criteria: comparative merit, need, use, age and value.

Most literature pertaining to health care is of dubious value within five to ten years of publication. An old book in most fields of clinical medicine is more than worthless. If it contains obsolete information, it often is downright dangerous. It is no longer necessary for a small hospital library to retain retrospective journals beyond five years. By interlibrary services available from the Bio-Medical Library of the University of Minnesota and from the Mayo Clinic Library, photocopies of articles needed can be procured at a nominal fee.

Periodical Indexes

Money spent in embalming restrospective journals in buckram can be more wisely invested in subscribing to a few key indexes. Serious consideration should be given to subscribing to three basic indexes. For approximately one hundred dollars, CUMULATIVE ABRIDGED INDEX MEDICUS,[2] CUMULATIVE INDEX TO NURSING LITERATURE,[3] and HOSPITAL LITERATURE INDEX,[4] for 1970-1972 can be procured. This expenditure will allow the hospital staff bibliographic access to approximately 600 journals—all containing potentially relevant articles on health care delivery.

Indexes to the journal literature perform a dual function: (1) they are the best tools for retrieving needed information from locally available journals; and (2) they are the keys to obtaining citations to needed articles from resource libraries through interlibrary loan services.

Journal Selection

Like books, locally available journals should be representative of the major fields of clinical medicine and the patient care given at the hospital. Valid criteria for journal selection must include a comparative analysis of several journals in the same field. Other criteria of parallel importance involve price, availability with memberships, and whether or not the journals are cited in the periodical indexes. The larger the hospital, the larger the professional staff, the more teaching and research conducted, the more journals which will be needed and hence, the CUMULATED INDEX MEDICUS, 1960+ should then be provided.[5]

Book Selection

One of the best methods of book selection is to obtain two or three current, authoritative titles in the same field on approval from a publisher, his agent, or a medical book store. By content analysis, an experienced health professional can make a valid judgment on selecting the best text to supplement existing local material and to meet the needs of local hospital professionals.[6]

Core Library Loans

Since May, 1970 Northlands RMP has loaned five model libraries to 76 hospitals requesting this service (Figure 1). In every instance the loan stimulated new book purchases by the hospital. Two of the lists, the CORE MEDICAL LIBRARY[7] and the CORE NURSING LIBRARY,[8] were developed at the Postgraduate Medical Institute of Boston by Stearns and Ratcliff. The IOWA CORE LIBRARY list —geared to the small community hospital—was developed by the Iowa Regional Medical Program. The EMERGENCY CARE LIBRARY and the INTENSIVE CORONARY CARE UNIT SHELF lists were developed in Minnesota by Northlands RMP and Minnesota Heart Association respectively. To maintain currency, new editions are added upon publication.

The Library Supervisor in Small Community Hospitals

Most hospitals under 300 beds cannot afford to employ a full-time professional librarian. However, every hospital should appoint one employee to serve as library-supervisor, and with this ap-

Figure 1

pointment, allocate adequate time to fulfill the responsibilities involved. A successful combination of duties has been a half-time librarian and a half-time secretary to a Director of Continuing Medical Education, or to the Director of Inservice Education. When deliberately sought, a local resident with library training or experience can frequently be found. A half-time position as a hospital librarian often appeals to a young married woman in the community.

Library Workshops

Under Northlands RMP sponsorship and at the invitation of hospitals, one-day workshops on hospital librarianship are being held in every region of Minnesota, (Figure 2).

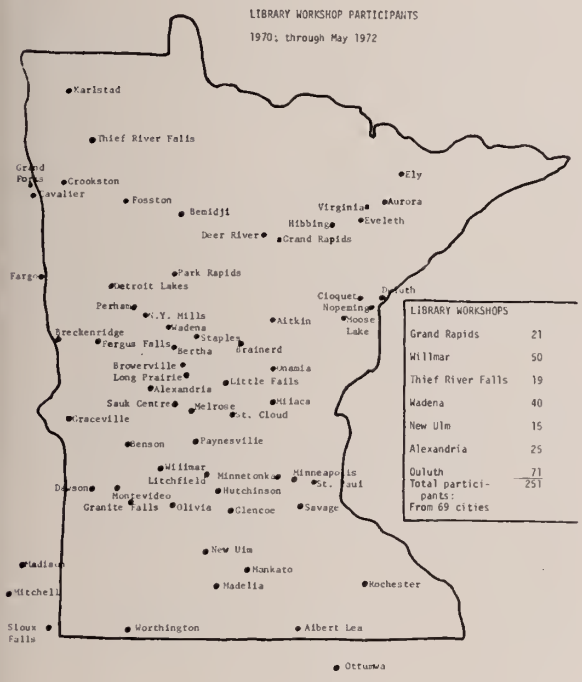

Figure 2

Not every hospital has an employee designated as library supervisor. Frequently participants at hospital library workshops are members of a hospital library committee, including physicians, hospital administrators and nurses. Stimulated by a sincere desire to learn more about developing and improving hospital library services, they come to learn about the basic elements involved—including the need for local library manpower and for funding the services. In order to be effective, library workshops must involve staff members who make final decisions about the development and improvement of hospital libraries.

Invitations to workshops are issued to nearby hospital administrators and identified health professionals who have requested library services from Northlands. Workshop participants come from several disciplines including physicians, nurses, administrators, therapists, technicians, medical records personnel, secretaries and librarians.

The agenda for each workshop varies somewhat depending upon the needs, interest, jobs and backgrounds of registered participants. Generally, two broad subjects are presented: (1) organizing and maintaining a local library service; (2) obtaining interlibrary services from the Mayo Clinic Library and the Bio-Medical Library at the University of Minnesota. A take-home kit is provided for further self-learning.

Apprenticeship Training

To meet a specific need for a deeper, more comprehensive training in hospital librarianship, apprenticeships have been arranged upon request by Northlands RMP. Supervised hospital library field work provides a tutorial learning experience in an ongoing library for a half-time hospital library employee. The field experience is matched as closely as possible with the needs of the new employee and her duties to her clientele at her base hospital. Matching elements include: size of hospital; size of medical and hospital staff; patient care; services; education programs; teaching programs; geographical location; long-term goals for library services; proximity to a model library and to an experienced, fully-qualified hospital librarian.

Short-term apprenticeships can be arranged for a one or two-week period. When feasible, arrangements can be made for a new hospital librarian to commute one day per week over an extended period of several weeks to receive on-the-job training from a nearby hospital librarian.

The quality of library services given is directly related to the motivation, ability and training of the person functioning as librarian. No one can function effectively without proper orientation and training.

Consultant Services

Since every hospital cannot have a professional librarian, consultation services of a certified medical librarian are frequently needed. The Liaison Librarian of NRMP has provided this service to over 112 hospitals and clinics in Minnesota and adjacent areas since 1970. (Figure 3). The re-

quests show a crucial need for expert help in developing and improving hospital libraries outside the urban areas. Consultations have been held on the following problems: planning and redesigning library facilities; evaluating and discarding local materials; organizing materials; developing multi-media services; establishing policies of services to students receiving field training; revitalizing the library committee and establishing short-term and long-range plans for expanded services.

Figure 3

Many talks have been given, upon invitation, to medical societies, hospital and clinic staffs, hospital administrators, nurses, medical technicians and medical record personnel.

These encounters lead to varied and multiple requests for extended library services from Northlands and from the medical center libraries, as professional staff become aware of their availability. The majority of requests are filled through correspondence and by telephone, as they pertain to specific materials or information.

Medical Library Assistance Extension Act of 1970

Medical Library Resource Grants authorized by the Act are meant to stimulate local support for upgrading library resources or services. The Improvement Grant program is directed to hospitals and health care institutions which need to establish a library or to improve and expand their basic resources. It is a one-year, nonrenewable grant in an amount up to $3000. An application kit, which includes a policies and procedures manual, is available from National Library of Medicine, Extramural Programs, Resources Division, Bethesda, Maryland 20014.

As of July 1972, sixteen health care libraries in Minnesota received funded grants under this Act. Six applications are pending and another eighteen health care institutions have written for the application material.

Extension Services from Mayo Clinic Library and Bio-Medical Library

To meet the increasing demands for interlibrary loans and other services from hospital libraries and their users, the position of Extension Librarian was established at both the Mayo Clinic and the Bio-Medical Library in September, 1970 (Figure 4). These Extension Librarians handle all requests from libraries and health professionals in outlying areas of Minnesota. By tapping their own resource library either Extension Librarian can supply materials needed by practitioners in any locale.[9] The Extension Librarian provides the link between the local library supervisor or practitioner and the resource libraries in Minnesota, Midwest Regional Medical Library in Chicago and the National Library in Bethesda, Maryland.

The two medical center libraries extend the benefits of their resources to all practitioners and health care institutions in Minnesota. The only

Figure 4

charges are a nominal handling fee plus photocopy costs. The rapidly increasing outreach services are shown in Figures 4 and 5 and the Table.

Figure 5

Biomedical Serials, 1972

To further simplify the procedure of obtaining a specific article from a specific journal held at either Bio-Medical or the Mayo Clinic Library, Northlands RMP published a joint list of the serials held by these libraries in May, 1972. The user of this volume can verify whether or not the desired journal is available at one or the other library. *Biomedical Serials, 1972* is distributed free of charge to Minnesota hospital or clinic libraries upon written request to the NRMP Liaison Librarian.

Computerized Literature Searches

Any practitioner in Minnesota can obtain a bibliography of the latest literature on any biomedical subject by requesting a MEDLINE search.

MEDLINE (MEDLARS [Medical Literature Analysis and Retrieval System] On-Line) is a national bibliographic search service available since June, 1972, to Minnesota physicians through the Bio-Medical and the Mayo Clinic libraries. By means of a computer terminal and a telephone link it taps a computerized data base initiated by the National Library of Medicine. The MEDLINE data base consists of over 400,000 articles from over 1100 health science journals cited in Index Medicus since January, 1969. To maintain timeliness, citations will be added and dropped annually.

At Bio-Medical Library, during the first year of MEDLINE operation, service will be limited to calls from practitioners outside the Twin City area. Practitioners in the metropolitan area can obtain MEDLINE searches through their local hospital or medical society librarians.

In order to request a MEDLINE search, an outstate physician can call the Minnesota Medical Information Service operator. (MMIS) toll-free at 1-800-552-7210.* The operator will ask for a description of the problem, record the information and forward the request to the MEDLINE librarian at the Bio-Medical Library. If necessary, the librarian will return the call to verify the interpretation of the problem. The bibliography obtained from the computer search will be mailed to the practitioner. Photocopies of specific articles can also be sent if desired. During the first year, there is no charge for MEDLINE searches other than the cost of photocopy at ten cents per page and a dollar handling charge per order mailed.

MEDLINE service is also available at the Mayo Clinic Library. For detailed information on Mayo services, contact the Extension Librarian, Mayo Clinic Library, 200 First Street S.W., Rochester, Minnesota 55901 or phone: 1-507-282-2511, Extension 2061.

TABLE
Library Extension Services from Biomedical and Mayo Clinic Libraries
1969 and 1971

Services to Hospital Libraries & Practitioners in Minnesota	Biomedical Library 1969	Biomedical Library 1971	Mayo Clinic Library 1969	Mayo Clinic Library 1971
1. Number of Hospital libraries loaned material located in Metro area	11	14	5	14
2. Number of Hospital libraries loaned material located in Outlying areas	8	32	2	20
3. Total number of requests filled for Outlying practitioners via hospital libraries & clinics	185	356	6	241
4. Total number of requests filled for Metro libraries: hospital, clinics	4275	7228*	21	584
5. GRAND TOTAL REQUESTS FILLED (items 3 + 4)	4460	7584	27	825
6. Literature searches & Bibliographies compiled for practitioners in outlying areas	—	108	—	40
7. Reference questions answered for practitioners in outlying areas	—	50	—	17

*Requests averaged 16 per day.

*MMIS is a central information service providing Medical Library Service, Dial Access Tapes, Drug Information and Medical/Dental Specialty Advice. It is sponsored by the University of Minnesota and partially subsidized by NRMP.

Summary

Since 1970, a cooperative effort has been made to improve, equalize and expedite aeeess to published literature for health professionals in Minnesota. To help interested hospitals with library development, the following services are available from Northlands RMP: core library loans; hospital library workshops; apprenticeship training and consultant services.

A nationwide network of biomedical libraries was established by the National Library of Medicine. All medical and hospital libraries are automatically part of this network. By linking and sharing existing library resources at key eenters, supplementary services become accessible to practitioners in hospitals and other health care institutions located away from large libraries. Medieal Library Resource Grants are available under the Extramural Programs, Resources Division of National Library of Medicine.

The Bio-Medical Library at the University and the Mayo Clinic Library, through their Extension Librarians, offer: interlibrary loans; photocopy services; reference services and literature searches. Through them, libraries throughout the nation can be tapped when needed material is not available within the state. The role of these resource libraries is to supplement—not supplant—the hospital library.

As the center for on-site information services, the hospital library must also function as the conneeting link for interlibrary services from larger resource libraries. The effectiveness of the biomedical library network at the patient care level is dependent on the quality of the hospital library.

Patient Education in Community Hospitals

D. D. ETZWILER, M.D., M. TYRELL, B.A., M. ULRICH, M.P.H., J. WRIGHT; M.A., AND A. HIRSCH, M.P.H.

OVERWHELMING DEMANDS are presently being placed upon the health care system of this nation. These forces seek to improve not only the quantity and quality of health care available but to simultaneously decrease its cost. The major response to these stimuli has been to train more allied health personnel who can quickly increase manpower capability at a minimal cost. In 1970 the ratio of allied health personnel to physicians was already 16 to one; and it is anticipated that by 1980, this figure will have increased to 25 to one.

Medical schools are being encouraged to escalate the size of their classes; two year schools of medicine have been expanded to four year programs and numerous new schools are being established. These methods of meeting expanding health care needs are merely an extension of an existing system where professional medical personnel assume a very active role in the treatment of a very passive patient.

The complex nature of today's health care needs demands a more comprehensive and creative approach. The leading causes of death today result from chronic illnesses such as heart disease, cancer, stroke, diabetes, respiratory and renal disease. These conditions require careful management over long periods of time. Merely increasing the number of health care professionals does not insure improved management of these chronic illnesses.

The greatest responsibility for health management lies with the patient himself. It is the patient who must carry out the day-to-day management of his illness while the physician and his co-workers must assume an advisory or supportive role. There has been little recognition or acknowledgement that the most important person in the health care system is the patient. In order for the patient or members of his family to effectively participate in management of a disease, they must understand their particular roles and responsibilities. Proper care of chronic diseases can only be achieved by informed patients cooperating with knowledgeable and interested professional personnel.

Recently several studies have been conducted to determine what the diabetic and his family know about the condition with which they live and assume significant responsibility.[1,2,3] The results were appalling, such as: More than 50% of the juvenile diabetics didn't understand acidosis and 50.4% didn't know the time-action of insulin they took each day. McDonald of the U.S. Public Health Service conducted a national study among diabetics and reported similar findings.[4]

In an effort to improve the patient and his family's understanding and knowledge of the disease, the Diabetes Education Center was established in Minneapolis. The Center serves as a regional resource where practicing physicians can refer their patients for indepth educational experience; and provides an educational program where professional health care personnel can obtain comprehensive training in the management and education of the patient with diabetes. The concept of patient education as an integral part of quality health care, however, is poorly understood and accepted. Consequently, a project was developed by the Minneapolis Diabetes Education Center to assist in investigating this aspect of health care. The program described here was conducted between June of 1969 and April of 1972.

Project

The objectives of the Diabetes Regional Center Project were:

1. To study current methods for delivery of health services to individuals hospitalized with a chronic disease.
2. To determine how this care can be improved.
3. To develop the necessary programs, materials.

This demonstration project was sponsored by the Diabetes Education Center, Minneapolis, Minnesota. It was a component of Northlands Regional Medical Program, Inc. Supported by HEW grant #5 GO3 RM-00021. The opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

Dr. Etzwiler is Director, Diabetes Education Center, Pediatrician, St. Louis Park Medical Center.

techniques, etc. for implementing such improved care.
4. To evaluate and summarize the experiences of the program in "key" hospitals.
5. To begin peripheralization of the program to small communities in the region.

Three hospitals were chosen to be studied during this project period. The first two hospitals involved, A and B, were chosen because they had differing locations, contrasting patient populations and needs. Hospital A is a new 378-bed general hospital located in suburban Minneapolis while Hospital B is an older 370-bed general hospital in downtown St. Paul. Both institutions had directors of medical education and administrators interested in patient education. The third hospital, C, is a 423-bed general hospital located in the central areas of Minneapolis. This hospital constituted a teaching and community service facility used by many different population groups and promised enthusiastic administrative support.

A Coordinator of Patient Education was hired for each hospital. Three of the four coordinators had nursing backgrounds and two had advanced degrees in health education. The coordinators chose not to stress their nursing backgrounds since this would identify them with traditional concepts and roles, thus limiting their staff and administrative mobility.

Since no previous guidelines were available, the job description of the coordinator had to be determined through trial and error.

The responsibilities of the Coordinator of Patient Education are now described as:

1. To become acquainted and identified as a resource.
2. To determine the educational needs of diabetic patients receiving care in the particular hospital.
3. To assess the resources and barriers pertaining to the establishment of a patient education program.
4. To devise a plan or system to initiate or improve patient education programs within the hospital.
5. To implement such a plan.
6. To evaluate the plan's effectiveness.

The Coordinators familiarized themselves with their respective institutions by attending meetings and conferences, visiting the floors, and participating in activities designed to acquaint them with all personnel. Simultaneously, they acquired information on the hospital's needs and resources. In Hospital A, for example, a survey of patient records revealed 194 patients were discharged with a diagnosis of diabetes mellitus over a four month period. Two-thirds of these were between 51 and 80 years of age with a ratio of 95 male to 99 females. Seventy percent were Protestant and all but one was Caucasian. The average length of stay was 11.5 days in contrast to 6.6 for the entire hospital population. The majority of these patients came from the surrounding suburban area where socio-economic characteristics revealed the population to be middle class, most of whom had a high school education and an average income of $7,000 to $15,000 per year. Patient teaching programs in diabetes had been initiated at the hospital in 1964, 1966, and 1968, but they encountered difficulty because physicians failed to order "education," and floor personnel forgot about the program.

Similar studies were carried out in each hospital to determine its individual characteristics and profile. All coordinators began by organizing an interdisciplinary committee on Patient Education. Committee members were chosen, volunteered, or assigned by administration. They included representatives from Nursing, Medical Staff, Occupational Therapy, Social Services, Laboratories, X-Ray, Medical Records, Pharmacy, Library, etc.

Despite employment within the same institution, the lack of communication among interdisciplinary groups represented on the committees was astounding. The first objective of each committee was to learn to communicate and function together as a group. All committee members also sought to increase their own knowledge of diabetes by reading; sharing reports; assembling diabetes literature; sponsoring, attending, and participating in lectures and conferences; as well as enrolling in the five-day educational course for allied health professionals at the Diabetes Education Center in Minneapolis.

With increasing insight into their own needs, each committee chose to assess knowledge of diabetes and its management among other members of the "health team" in their own institutions. For instance, one committe chose to evaluate the patient population and devised a 35-item test on diabetes. This was pre-tested on the institution's professional staff. Ninety-six percent of the staff thought the test suitable as a gross measurement of knowledge of staff and patients. The test results among the patients and professional groups are shown in the Table.

TABLE
Results of 35-Item Test on Diabetes

Residents/Interns:	Number Wrong	Score
Average	8	76%
Range	4-11	69-89%
Nurses:		
Average	9	78%
Range	1-16	45-99%
Patients:		
Average	18	49%
Range	7-35	0-80%

Each hospital conducted such studies which stimulated interest and inservice education activities. One institution organized a two-day symposium on diabetes for the medical house staff.

Initially, it was difficult to identify all diabetics being admitted to the hospital. Two institutions utilized the PAS system of record analysis. It was found however that "diabetes" was sometimes omitted from the admitting or discharge diagnosis, particularly when the patient was suffering from a multitude of problems. The most valid source of diabetes diagnosis in one institution was found to be the Medical Records office rather than Admitting, since the former tends to group patients in 24-hour collections while Admitting is continually adding to its list throughout the day. Cross-checks to pick up the "unidentified" diabetic in-patient may be made with the Dietary Department or the Pharmacy Department. "Diabetic Diet" orders or prescriptions for insulin or oral hypoglycemic agents may assist in locating these patients. Laboratory personnel also assist by reporting patients with elevated blood sugars. Once the institution becomes sensitized to identifying the diabetic patient, ward secretaries become the most effective and reliable resource. However, such cooperation and assistance is generally achieved only after a long period of institutional indoctrination, education, hard work and frustration.

At the time the program was initiated, there was only one diabetes teaching program in the three institutions. It had been initiated in the Spring of 1968. Seventy-two patients, or an average of six patients per month, had been referred to classes during the first year of operation. Only 56 patients had completed the series of five classes during the first 17 month period. Analysis of hospital records, however, revealed the *daily* hospital census ranged from eight to 20 diabetics. The program had no written objectives but it was assumed to be suitable for the newly diagnosed diabetic and those out of control. It was anticipated the program would be attended by members of the patient's family and by out-patients. However, attendance by family members had been disappointing and only one out-patient had participated. A charge was made for the course and in most instances this was covered by hospital insurance.

Once the Coordinators and their committees had gathered information on existing teaching programs, defined patient profiles and needs, assessed hospital barriers and resources, and increased their own awareness of diabetes and education, two of the hospitals initiated education programs and the third strengthened its existing effort.

Teaching Programs

The nature, content and extent of patient education programs to be conducted within each hospital had to be determined. The committees recognized that most hospitals were acute care facilities where ill patients are admitted, treated and discharged as soon as possible. It was generally agreed, however, that hospital in-patient teaching programs should include the following fundamental information of the disease and its management:

1. Basic concepts of diabetes.
2. Insulin and insulin administration *or* oral hypoglycemic drugs.
3. Urine testing for sugar and acetone.
4. Diet.
5. Acute complications (hypoglycemia and acidosis).
6. Personal hygiene.
7. Exercise.

It was recognized that extensive in-patient teaching programs should not be provided in most institutions because of (1) variations in individual patient needs and receptivity during hospitalization; and (2) limited time, personnel, finances and facilities. The presence of the Diabetes Education Center in the community provided a resource where patients could complete an indepth comprehensive educational program on an ambulatory basis at a minimal cost and during a more appropriate phase of their disease.

The need to individualize certain aspects of patient education was recognized. Group patient classes have the advantage of saving time and minimizing costs; but not all techniques and materials are effective for teaching all patients in a single class. In order to meet this challenge, two com-

mittees developed initial interview forms to be administered by professional persons upon patient admission, or when feasible. A self-assessment form was devised to determine what the individual patient does or does not know about his disease. This information plus the patient's medical history, nursing and nutrition interviews, and input from social service provided a wealth of information. It was necessary then to devise a plan to assess and exchange this data among participating personnel. Interdisciplinary patient care conferences, or PEP (Patient Education Planning) conferences as one institution chose to call them, were initiated. Team members exchanged data obtained both formally and informally, and an individualized patient education plan was devised. Information concerning such items as disease acceptance, visual status, dexterity, personality, economic problems, marital difficulties, language barriers, educational background, etc. were discussed Having pooled this data, the "teachers" then established realistic goals for the patient and the health care team.

Assistance in determining program content and teaching materials was obtained from the staff's own investigational activities and with guidance from the staff of the Diabetes Education Center. New props, plans, and programs were created by the individual institutions as they sought self-identification, expression, and acclaim.

Blocks and Pressures

Planning a teaching program is difficult even for a committee of interested and knowledgeable individuals. The greatest challenge, however, is to implement and maintain a health education program, for this requires institutional acceptance and commitment. Communication and cooperation were not always maintained on an interdisciplinary basis within the Patient Education Committees, and these were frequently not achieved even on an intradisciplinary level outside of the committee. Personality and political differences and concerns within a hospital reflect the same variations seen within the community. The charismatic individual who can be most effective in establishing teaching programs or instigating institution change is not always found in positions of power on the institution's Table of Organization. Conversely some of the greatest "blocks" may be applied by hospital "leaders" who feel threatened for one or another reason. Verbally, almost all hospital personnel agreed that patients should be taught. However, the depth of that conviction quickly became evident when the questions of cost and commitment were introduced.

As part of this study, one author chose to assess existing patient educational programs in 26 hospitals in the Twin Cities area. When the administrators of these hospitals were asked if their institutions provided programs for patient education, all replied "yes." When asked to identify an individual who coordinated these efforts or worked in this area, only 12 of the 26 institutions could produce a name. In most instances (58%), responsibility for patient instruction was defined as a function of the nursing service. Only 15 of the 26 hospitals reported having purchased any materials for patient education during the previous year. Only three institutions had any budget allocations made specifically for patient education!

Evaluation

As a consequence of this program diabetes teaching programs were initiated in two hospitals. In the third hospital innovations were made, and institutional awareness increased so that during the final four months of the study, patient attendance rose to an average of 14.5 patients/month with 23 family members, and 13 patients repeated one or more of the classes.

During the period of investigation one of the hospitals experienced a change in administrators; this resulted in an almost total loss of support for patient education. The committee in that institution was told to submit a budget for the following fiscal year; and although the work was verbally supported in committee hearings, the request for funds was denied. Portions of the committee still meet with a health educator at planned intervals, but "acceptance" of patient education within the institution is low.

One hospital not only accepted the concept of patient education but has established an independent Department of Health Education with a budget of over $300,000 a year. This hospital prides itself on this unique service to the community and has received national recognition. The following improvements[5] have occurred as a result of this effort:

1. Total hospital communications have increased because of interdisciplinary cooperation.
2. Staff members have been stimulated to increase and update their individual knowledge and skills.
3. A valuable stimulus for planning and implementing team projects has been provided.

4. Physical care of patients has improved.
5. Patient satisfaction has increased.
6. The institutional image in the community has been improved.

Peripheralization of this program has stimulated initiation of patient education teaching programs in many cities, towns, and institutions throughout the region and the nation. A standing committee on Regional Medical Programs and Diabetes Education Centers has been established within the American Diabetes Association as a direct result of this project, and a one-day program devoted to patient education is now part of the Annual Postgraduate Course of the American Diabetes Association.

The concept that the patient is an essential part of the medical team and that his education and cooperation are essential to quality health care is still rarely understood and poorly accepted. In September 1971 the President appointed a commission to study Consumer Health Education in this nation. The results of that study will probably be released sometime in the near future. Patient education and his incorporation into the health care team promises to produce one of the greatest impacts on health care of the decade!

Summary

Health care and needs are currently undergoing great changes. One of the greatest of these promises to be the involvement of the patient in his own health care. The establishment of Patient Education in Community Hospitals in order to provide patients with sufficient knowledge to become an effective member of the medical team is a difficult task. Experiences in three such institutions are described herein.

Education of Non-Physician Personnel in Stroke Rehabilitation and Chronic Illness

ANITA P. SMITH, PH.D.

Implicit in the concept of rehabilitation is a commitment to provide continuity in patient care, not only in the hospital but beyond it. Physicians, because of their limited numbers and crowded schedules, cannot be expected to meet this need without the assistance of other informed persons in the community. In order to provide the additional health manpower required, it is necessary to train and use key resource groups, such as the clergy and family members, as well as to upgrade the technical skills of presently employed health professionals. The Sister Kenny Institute presented a means of realizing the goal of continuity in care of the stroke patient by educating nurses, social workers, the clergy and families to more effective ways of meeting the patient's physical and psychological needs.

Objectives

In March, 1969, the Sister Kenny Institute initiated its project on "Improving Stroke Rehabilitation Through a Regional Program of Continuing Education." The overall purpose of the program was to help provide improved and more comprehensive health care for stroke patients and other chronically ill or disabled persons by: (1) updating and upgrading the knowledge and skills of those involved in the patient's rehabilitation, and (2) augmenting available health manpower.

The specific objectives of this project were:

1. To increase the numbers of professional persons able to provide improved treatment and care of stroke patients.
2. To upgrade the technical skills and knowledge of health-related professionals regarding stroke and rehabilitation, emphasizing the broadened scope of activity possible in traditional professional roles.
3. To facilitate the development of dialogue and inter-institutional cooperation throughout the region in the joint effort required to improve the care of stroke victims.
4. To further the knowledge and understanding of the regional lay public, especially the families of stroke patients, regarding the medical and psychosocial aspects and implications of stroke as related to the treatment and care of the affected family member.

Project Description

This project consisted of six independent but related programs of continuing education, all offered over a three-year period from March, 1969, to April, 1972. Three in-depth courses were offered at the Sister Kenny Institute, Minneapolis, a total of 27 times: *Nursing Care of the Long Term Patient* (14 course offerings); *Social Work Refresher and In-Service Course* (five course offerings); and *The Clergy and Rehabilitation of the Chronically Ill* (eight course offerings). The *Community Nursing Education Seminars* (422 sessions) and *Stroke in Your Family* (22 seminars) were offered on-site as requested by individual institutions and local communities. The *Regional Service to Schools of Nursing* program was conducted only during the second year of the grant. Each course charged a nominal tuition fee to insure student commitment in attending with out-of-state applicants accepted but at a regulation tuition rate, e.g., $250 per student for *Nursing Care of the Long-Term Patient* (vs $50 for Minnesota students). Living stipends for out-state Minnesota students were available at $16 per day. A summary description of the project units can be found on the following page.

The faculty for these courses were recognized experts in their particular specialties. Included were physicians, social workers, psychologists, occupational and physical therapists, nurses, voca-

This demonstration project was sponsored by the Sister Kenny Institute. It was a component of Northlands Regional Medical Program, Inc. supported by HEW grant #5 GO3 RM-00021. The opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

tional counselors, speech pathologists and other rehabilitation professionals from the Kenny Institute, the University of Minnesota, community agencies and private practice.

All of the programs discussed here utilized a variety of teaching methods with the particular method used depending on the topic and type of material being presented. These included: lecture, demonstration-return demonstration, clinical observation, clinical practice, tours, attendance at patient-planning conferences, seminars, problem-solving discussions and individual study assignments. Audio-visual media such as films, filmstrips, slides, overhead transparencies, video tapes and closed circuit television were used throughout the courses to increase learning and retention.

Although program activities remained substantially the same in general purpose and structure throughout the three years of the project, certain changes did occur during that time. First, course objectives and content were broadened to apply to a wider scope of disabling conditions than stroke alone, e.g., heart disease, cancer, arthritis, spinal cord injury, etc. Second, the emphasis was changed from refresher and pre-service training in the *Social Work* course to in-service, as this need became apparent toward the end of 1970. Third, a team concept was introduced into the Community Nursing Education program with the addition of a physical therapist to the staff. Finally, it became necessary, due to decreased funding, to reduce project personnel time, eliminate expansion activities and offer fewer courses and seminars.

Project Evaluation

Evaluation methods for assessing the achievement of program objectives encompassed a considerable range of procedures. Student knowledge, skills, attitudes, performance with patients and changes in all these dimensions were examined. Criteria were established to determine successful achievement of each goal.

Criteria were defined quantitatively for those objectives dealing with increasing the number of stroke-sophisticated manpower and with furthering communication and cooperation among health-related professionals. The following were considered indicators of goal achievement: the number of students attending the courses; what geographical areas in the state they represented; and the number and types of participants from various disciplines who, by involvement in the courses,

SUMMARY OF SISTER KENNY INSTITUTE CONTINUING EDUCATION PROGRAMS

Course	Eligibility	Times Offered Annually	Class Limit	Length of Course	Course Content	Locale
Nursng Care of The Long-Term Patient	R.N.'s in positions of educational leadership	4-5	18	2½ weeks with an optional week of supervised practice	85 hours on nursing techniques, psychosocial understanding and communication methods to improve stroke care; also content for use in in-service education.	Kenny Institute for course: employing institution for in-service education.
Community Nursing Education Seminars (Field Education)	Community agencies, nursing homes, hospitals, and professional organizations	Arranged individually	Open	Arranged individually	Short training programs conducted by Kenny nurse-educator, on nursing techniques for patients with stroke and other long-term illnesses.	Local communities
Regional Service to Schools of Nursing	Any accredited educational program for vocational, technical, or professional nurses.	Arranged individually	5 or more nursing students accompanied by an instructor	3 hour seminars or 3-5 day clinical experience in long-term nursing care.	Lecture on role of the rehabilitation center and special nursing care of the patient with a long-term illness. Discussion of topic elected by the nursing school.	Kenny Institute
Social Work Refresher and In-service	B.A. plus social work experience or graduate credits in social sciences	1-2	15	2 weeks	42 hours of instruction on current methods and practice in social work, medical and psychosocial aspects of chronic illness, and community agencies and resources; 18 hours in clinical settings.	Kenny Institute
The Clergy and Rehabilitation of the Chronically Ill	Ministers, priests, rabbis, hospital and other professional persons concerned with religious implications of chronic illness.	3 times annually for 3 day course. Arranged individually for 1 day seminar.	20 for course	3 days for course 1 day for seminar	18 hours of instruction on medical and psychosocial aspects of chronic illness, community resources and role of the clergy.	Kenny Institute for course. Local communities for seminar
Stroke in Your Family	Families of stroke patients, physicians, nurses, and other interested medical personnel.	Arranged individually	50	1 half day as requested	Approximately 4 hours of instruction on medical aspects of stroke, communication, ADL's and community resources.	Local communities

broadened their traditional roles through new interactions and activities, e.g. teaching or supervising students.

Criteria for successful achievement of the project objectives concerned with updating and improving stroke knowledge, skills and practice of both health professionals and laymen were directly related to evaluation of the individual unit (course) objectives. Evaluation techniques for appraising achievement of goals included role-playing, problem situations, open-ended discussion, case studies and quizzes. Observation and rating of student-patient interaction and of task performance were utilized.

Results

Project Objective 1

To increase the number of professional persons able to provide improved treatment and care of stroke patients.

The number of nurses, social workers, clergy, other health professionals and family members who attended the continuing education courses and seminars offers conclusive evidence that this objective was achieved. A total of 20,392 students participated in the project during its three year existence for an average of approximately five hours of instruction per student. Of the total students, 405 attended the three in-depth courses at Kenny Institute with an average 65 hours of instruction per student. The outreach program of community education seminars, including *Stroke in Your Family,* involved 19,418 students from throughout Minnesota for an average four hours of instruction each. *Regional Service to Schools of Nursing,* offered only during Year Two, provided eight instructional hours per student to 569 nursing students. Table 1 details the number of students attending each program.

TABLE 1
Three-Year Summary of Student Attendance

Program	Fiscal Year 1	Fiscal Year 2	Fiscal Year 3	Three Year Total
Nursing Care of the Long-Term Patient	63	81	58	202
Refresher and Pre-Service (In-Service) Course for Social Workers	22	45	22	89
The Clergy and Rehabilitation of the Chronically Ill	45	40	29	114
Stroke in Your Family	380	520	362	1,262
Community Nursing Education	3,638	5,162	9,356	18,156
Regional Service to Schools of Nursing	—	569	—	569
Total	4,148	6,417	9,827	20,392

The regional impact of the program has been outstanding with all sections of the state represented by participants. Out of 87 counties in Minnesota, health related professionals from 77 counties, or 88.5%, attended these programs. Only Big Stone, Clearwater, Grant, Kanabec, Lake of the Woods, Mahnomen, Murray, Red Lake, Traverse and Wabasha counties were not represented. The community and/or family stroke education seminars were presented in 70 Minnesota counties. Table 2 indicates the geographical distribution of the students at the Kenny Institute based courses.

TABLE 2
Geographic Distribution of Kenny Students

Georgraphic Area	Year 1 No.	Year 1 % age	Year 2 No.	Year 2 % age	Year 3 No.	Year 3 % age	Total No.	Total % age
Twin Cities	64	49.2	80	48.1	51	46.8	195	48.1
Out State	51	39.2	56	33.7	42	38.5	149	36.8
Out of State	15	11.6	30	18.2	16	14.7	61	15.1
Total	130	100.0	166	100.0	109	100.0	405	100.0

In 1970, approximately 46.7% of Minnesota's population lived in the Twin Cities metropolitan area. It should be noted that a comparable ratio, or nearly half of the students, attending the in-depth longer courses were from the Twin Cities area with the percentage decreasing slightly from Year One to Year Three. Out-state representation was lower during Year Two but averaged approximately 39% for the other two years.

Finally, an additional increase in the numbers of those providing improved stroke care resulted from the return of *Social Work Refresher* students to medical employment after attending the course. Of the 89 students in the *Refresher and Pre-Service (In-Service) Course for Social Workers,* 35 were refresher students. Twenty-four (68.6%) of these 35 students returned to positions in the medical field, two became ill and could not seek employment, four are not yet available for employment and five could not be reached for follow-up.

Project Objective 2

To upgrade the technical skills and knowledge of health related professionals regarding stroke

and rehabilitation, emphasizing the broadened scope of activity possible in traditional professional roles.

With the assistance of both educational and clinical experts, the curricula of the courses on *Nursing Care of the Long-Term Patient, Social Work Refresher and In-Service Course* and *The Clergy and Rehabilitation of the Chronically Ill* were all designed to meet the goal of upgrading technical skills and knowledge. In addition, the students were tested as to information and clinical skills learned, follow-up questionnaires were developed and on-site evaluations of student performance were conducted.

In the *Nursing Care* course the students were given a pre and post test of 48 questions. Test results indicated that prior to the course only half of the students could answer 70% of the questions successfully, whereas after attending the course all of the students could answer at least 73% of the questions. A low correlation ration of .355 between the tests showed a definite but small relationship indicating that scores on the post-test were only slightly influenced by pre-test results. We may, therefore, conclude that the students' knowledge of rehabilitation nursing increased as a result of course participation.

Six-month follow-up questionnaires to the nurses revealed that a majority of the students were still employed at the same institution. Student on-the-job changes related to course attendance were: (1) in-service training of staff in rehabilitation methods and techniques of nursing care learned at the course; (2) implementing an improved concept of rehabilitation by teaching patients new skills and encouraging greater patient independence; (3) practicing and teaching more effective means of communication between patients and staff; and (4) purchasing and modifying equipment for proper usage.

Site evaluations were conducted with 92 former students. Most considered the course to have been "excellent," "worthwhile," "helpful" and "pertinent." Moreover, each participant mentioned gaining insight from whatever portion of the course was applicable to her particular situation. New techniques and equipment were cited as presently being used regularly, and staff development programs had frequently been initiated.

Negative reaction was mostly related to expressed desire for a longer course with additional time available for clinical practice. Difficulty in implementing new methodology at the employing institution was also mentioned.

Students in *The Clergy and Rehabilitation of the Chronically Ill* were given a pre and post test of 20 situational, multiple choice questions. Only half of the students tested could answer 71.03% of the questions correctly before attending the course. After course participation, 82.4% of the students scored 15 (75% correct) or better. Inasmuch as the mean scores (pre: 14.206 and post: 16.5) were significantly different at the .001 level, we may conclude that course attendance significantly raised the students' level of knowledge regarding rehabilitation and chronic illness.

A follow-up questionnaire was developed to ascertain the students' evaluation of the material covered in the course. Thirty-four students (68% of those contacted) responded, and all regarded the course as contributing positively toward their effectiveness in ministering to the chronically ill. In regard to the amount of time allotted to various areas of knowledge, over 50% of the students indicated they would have preferred more information on the psychosocial aspects of disability and 32.4% requested more discussion of the relationship between the physician and the clergyman. Coverage of medical aspects of disability was judged excellent by 70.6% of the clergy.

Behavioral objectives were delineated for all content areas covered in the *Refresher and In-Service Course for Social Workers.* Students were asked to evaluate content areas as to significance and meaning for them. Those topics rated as excellent in organization and coverage were "Behavior and Learning Difficulties in Children," "The Meaning of Stroke," "Psychology of Death and Survival," "Community Resources for Crisis Intervention" and "New Directions in Health Careers." "Administration in Institutions Employing Social Workers" was considered least satisfactory. The students also rated the total course as outstanding in worth and of unusually high quality. Achieving the project goal to upgrade stroke skills and knowledge was further indicated by the 47 employed medical social workers who attended the course for in-service training purposes.

During the three years of the project, all Kenny course presentations were evaluated by the students as to organization/coverage and style/delivery. Comments were also requested regarding the overall character of the course. As a result

of these evaluations, appropriate changes were made in speakers, topic focus or other aspects of the course format.

Project Objective 3

To facilitate the development of dialogue and inter-institutional cooperation throughout the state.

In order to achieve this goal, each project unit involved health professionals from throughout the state in curriculum planning and course instruction. Where possible, former students were contacted and included in planning, teaching or evaluation capacities. The total group represented the full range of health disciplines and presented a unique opportunity for increased understanding and dialogue among these persons and the student professionals. Of a total 457 classes conducted for these courses, 79 (17.3%) were taught by University of Minnesota faculty including 34 from the Medical School, 28 from the School of Social Work and 17 from other departments. Instruction for 239 (52.3%) classes was provided by hospital personnel, specifically doctors, nurses, physical and occupational therapists, social workers, psychologists and speech pathologists. Although the majority of these hospital personnel were from the Twin Cities area, 21 (9%) were located outstate. 68 (14.9%) instructors were from social welfare agencies, and 28 (6.1%) were physicians in private practice.

Project Objective 4

To increase knowledge and understanding of the regional lay public, especially the families of stroke patients, regarding stroke.

Stroke in Your Family, as a vehicle for educating patients and their families, reached 1,262 participants from 18 Minnesota counties. Approximately half of these students were family members, and half were local health professionals. As mentioned earlier, community health professionals were regularly included in course planning and instruction.

At the conclusion of the course, *Stroke in Your Family* participants were asked to complete evaluation questionnaires describing the status of their stroke patient, what information received would help them to improve the patient's care and how this information would help. Although nearly every point of information was mentioned as helpful by someone, the suggestions considered most valuable related to patient self-help, individualized household equipment and utensils, patient exercise, techniques for moving and lifting, and explanation of patient attitudes. Participants felt the information given would enable them to help the patient be more comfortable, improve his attitude, make communication easier and contribute to a better understanding of the patient's problems. Repeatedly, the participants rated the presentations as excellent, informative, interesting and practical.

Conclusion

This project was originally designed as a statewide program of continuing education, and the pattern of student attendance indeed denotes an outstanding regional impact. Although nearly half of Minnesota's population lives in the Twin Cities metropolitan area, only 25.9% of the total student enrollment was from that section. Participation from outstate health professionals and laymen was therefore proportionately greater than might be anticipated. Of the 11 economic regions so designated by Northlands Regional Medical Program, those in the Central, North Central, and South Central portions of the state are represented more heavily than their ratio of the total state population would predict. However, the North, West and West Central regions were represented somewhat less frequently than their population ratio might indicate.

Overall, it may be concluded that the project goal has been realized of developing within local communities multidisciplinary clusters of stroke-sophisticated health professionals and laymen. With the encouragement and support of the project educators, many of these individuals are now able to conduct inservice training, family education and community programs on stroke, as well as to provide high quality medical care to stroke victims.

Obviously the need for such educational programs is evident, and health professionals throughout the state are eager to take advantage of opportunities to improve their patient care capabilities. Unfortunately, this project, with its diverse emphasis on centralized indepth courses as well as decentralized, outreach programs, cannot be integrated into any presently available educational structure. Highly specialized faculty are necessary to teach in the courses for rehabilitation nurses, the clergy and social workers; and the state technical, junior college and four-year schools

do not have sufficient qualified staff available. It is, therefore, advisable for future efforts and funding to be directed toward development of educational materials packages (audiovisuals, student handbooks and instructor guides) that will enable relatively unspecialized personnel in concerned communities and facilities to offer similar courses.

Summary

As a component project of Northlands Regional Medical Program, the Sister Kenny Institute, Minneapolis, developed a three-year integrated plan of continuing education on stroke rehabilitation and chronic illness. This program provided short courses for nurses, social workers, clergymen and families of stroke patients. In addition to increasing the number of stroke-sophisticated professionals and laymen, it has also been a project goal to encourage health professionals to incorporate new skills and knowledge into their own institutional programs or to replicate some courses in their own communities. By these means, it has been possible to multiply the effects of the project and help maximize the physician's efforts to provide improved patient care.

Improving Allied Health Capability Through Continuing Education

DOROTHY G. VERSTRAETE, R.D., M.S. AND DONNELL D. ETZWILER, M.D.

THE HEALTH CARE SYSTEM of the United States is at a point where any planned improvement in the quality of the services available must take into greater account certain non-medical factors. A very significant consideration is that of economics. Historically, the phrase "cost benefit ratio" has been an active part of the daily vocabulary of engineers and accountants but was not even included in the glossaries of the standard works for the health care specialties. Although there is general awareness of this spiralling cost among the nation's 3½ million allied health personnel, there is little anlytical understanding of its causes. If forced to consider basics, a significant majority would point to the familiar whipping boy "inflation" as the single most significant contributing factor and might cite the wider utilization of allied health workers as being another. They would probably state, and find general agreement, that whereas inflation adds to the cost but not to the quality of health care, at least the expenses entailed in broader use of allied health specialists bring a proportionate increase in the quality of care afforded the patient. That is a comforting thought, but is it rational?

One inescapable fact is that even with improved health as the object, there is a ceiling on the willingness and the ability of either the individual or the nation to continue to meet escalating costs. Any attempt to raise standards of quality while holding the line on costs must acknowledge that, although the inflationary spiral is beyond early control, the manner in which the various allied health specialists are utilized should be very much within the control of the health industry. Considering that personnel costs account for more than a solid 50 percent of hospital budgets, more efficient use of each member of the allied health team is a logical starting point in a program to improve the cost benefits ratio as applied to health care.

The program described in this paper is a joint effort of health professionals with the support of the Northlands Regional Medical Program, Inc., to work toward a partial solution in one allied health area. The project was designed to conserve manpower already trained and to upgrade the skills and level of performance of members of one health specialty—dietetics.

Manpower Needs

Historically, allied health workers fit into tight categories, with very little overlap of responsibility and with no progression, either between groups or upward, except within structured specialty groups. "Professionalism" of the allied health science specialties has been advanced and maintained by national associations which set educational standards for the specialty, and by licensure, registration, or accreditation where these apply to individual practitioners.[1] The American Medical Association, through its Council on Medical Education, is represented on boards that accredit education and training programs for 13 allied health professions. While it is true that such "professionalism" has been instrumental in setting and maintaining standards of preparation and (perhaps) performance, the rigid structure and lack of flexibility which result have had less desirable effects.

The wide use of health care professionals is defensible and desirable when improvements in patient care result and when total availability of health care is extended. Unfortunately, during the recent period of rapid change, no close administra-

This demonstration project was sponsored by the Diabetes Education Center, Minneapolis, Minnesota. It was a component of Northlands Regional Medical Program, Inc. supported by HEW grant #5 GO3 RM-00021. The opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

Dorothy Verstraete is Director of Nutrition Education, Diabetes Education Center; and Assistant Professor of Nutrition, University of Minnesota.

Dr. Etzwiler is Director, Diabetes Education Center; Clinical Associate Professor of Pediatrics, University of Minnesota and Pediatrician, St. Louis Park Medical Center.

tive scrutiny of scope and responsibility of each health specialty or analysis of job performance was attempted for allied health manpower. Accredited programs of preparation were equated with permanent competence, although costs can only be justified by continuing levels of excellent performance.

In the recent past, the chief area of interest in health manpower has been in the direction of increasing numbers. Both federal support and academic programs have been designed to facilitate production of manpower. Unequal attention was given during this period to the continuing education of specialists and to the revision of training programs in the light of present and future needs for particular *types* of personnel. Instead of reassessing traditional programs to promote flexibility and reducing patient care costs by utilizing specialists at their highest technical level, new specialties were introduced and approved through organization of new professional groups. Examples of these programs are the various technician specialists, the physician assistant, etc.

Dietitians are among the allied health workers to whom the observations above apply. The American Dietetic Association is the national profcssional organizaion which sets educational standards for undergraduate programs in dietetics, approves internships in dietetics, and sets requirements for registration of dietitians. It also grants approval for programs of continuing education to meet standards for maintaining registration.

Assessment of Regional Needs

Information on the subjective need for continuing education and the probable response of dietitians was obtained from a survey. With the cooperation of the Minnesota Dietetic Association, all persons working as "dietitians" in Minnesota were surveyed in 1968.[2] The questionnaire and the tabulation of the results were developed by the staff of the American Rehabilitation Foundation of Minneapolis. The Dietetic Association provided lists of American Dietetic Association members, non-ADA dietitians and consulting dietitians. In the course of the survey, respondents submitted names of other individuals who were working or had worked as dietitians. In total, 635 questionnaires were mailed; 419 (66%) were completed and returned. Of the 419 respondents, 277 (66%) were currently employed as dietitians; 162 (38%) full time; 79 (19%) part time; and 36 (9%) consultants did not indicate either full or part time. The 152 inactive dietitians (34%) who responded included: 29 (7% of 419) employed in other fields; 101 (24%) not employed; and 12 (3%) retired.

Three-fourths (319 or 76%) of those who responded to the survey indicated an interest in refresher training: 266 (63%) at the graduate level; and 53 (13%) at the undergraduate level. Of these 319, 231 currently were employed as dietitians and 88 were inactive; this represents 89% of the active dietitians and 65% of the inactive dietitians. Of the 101 inactive dietitians, 50% expected to return to employment.

Goals of Continuing Education in Health Specialties

In 1969, a vote of the membership of the American Dietetic Association approved registration based on a requirement for continuing education. Dietitians are among the very few health groups accepting mandatory education as a prerequisite to continuing registration.

Three factors operate to make educational programs in clinical nutrition a valuable state and national asset in dietetics.

First, the cost of dietetic internships, which is supported by hospital administration (and is therefore a part of patient cost) is becoming prohibitive. Dietetic internship availability is declining. Students fully qualified by undergraduate training cannot be placed in internships. In this situation, the undergraduate enrollment in dietetics is certain to decrease. Actual numbers of registered dietitians, trained in approved undergraduate programs *and* in approved internships will not meet the anticipated health care needs of the future. It is therefore important to conserve and use trained manpower, at least until opportunities for completion of dietetic training again become more available.

Second, it is the usual situation among allied health workers (largely women) that professional activity is often interrupted by marriage and family responsibility. Studies have shown that retraining programs have been successful in returning allied health specialists to active work.

National studies have shown that the number of nurses who return to active duty varies between 50-70% after refresher training.[3] Followup studies on Minnesota nurses who completed refresher training have been done by the American Rehabilitation Foundation. Questionnaires were sent to

279 nurses who had completed refresher training between 1960-66. One hundred and thirty (69%) of the 188 responding to the questionnaire had returned to work at some time after the course.

Refresher courses in other allied health areas have also been conducted by the American Rehabilitation Foundation with the aid of Community Health Services grants. Followup studies on those retrained in 1967 and 1968 gave the following results:

Specialty	Number Retrained	Number Reactivated	Percent
Occupational Therapists	17	14	82
Physiotherapists	23	20	80
Social Workers	33	33	100

It is difficult to obtain figures on return to work for clinical dietitians following refresher courses because formal courses of this type are not widely available in the United States, but it may be assumed that the pattern would be similar to other health workers groups' experiences.

Third, if the full utilization of already trained dietitians is a primary goal, it is imperative to provide for updating of knowledge and skill. The rapid advance in medical knowledge has major impact in the practice of clinical nutrition. New information and new techniques must be made available to all dietitians, both those in retraining programs and those currently employed. In addition, this type of education must be made available on a wide geographic basis, not only in the educational and medical centers of the area.

It is also vital to upgrade the skills of those persons functioning in the nutritional care of patients but who have had very little formal dietetic training. They are often the only community resource in nutrition.

Future Needs

Another important consideration in structuring education programs is the forward look required to identify needs of the future. Admittedly, it is difficult to predict skills requirements of the future, but certain information is available. The shift of patient load from acute care to continuing care beds is obvious.[4]

The interest in nutrition as an element of preventive medicine is also emerging, as is the new understanding that nutrition education is a necessary part of care for the disadvantaged of any type, as well as for the person suffering from a chronic condition requiring diet therapy.

Number of Beds in Minnesota Licensed Medical Facilities

Facility	1943	1971	Percent of Increase
General Hospitals	11,159	18,996	70%
Nursing and Boarding Care Homes	3,905	41,313	958%

In the light of the factors described above, a program of Continuing Education in Clinical Nutrition was designed and submitted to the Northlands Regional Medical Program, Inc. The program was approved and funded for a two-year period. It was operational from March 31, 1970, to March 31, 1972. The major goal of the project was the improvement of patient care through an increase in dietetic competence and availability.

Design of the Program

This Minnesota-Northlands Regional Medical plan was designed, in part, to increase the number of dietitians available for service in this allied health specialty by re-educating the once fully trained, but now inactive, dietitian in order to facilitate her return to employment. The group of inactive dietitians had been identified by the survey. Approximately 50 percent expected to return to work and 65 percent of the group requested programs of continuing education.

In order to increase dietetic availability, this program was also designed to meet the needs of "consulting dietitions" in Minnesota. These persons were working full or part-time, and many were employed by a number of institutions. Approximately 50 percent of this group had never been trained in clinical dietetics but were "consultants" to institutions engaged in patient care. These consultants were also identified individually by the survey.

A third group for which this program was planned was the isolated dietitians in the state who have very little opportunity to participate in programs of continuing education. Availability of competent clinical nutritionists throughout Minnesota depends in great measure on a program of modern diet therapy for this group.

An educational program of current information in nutrition and diet therapy for these three groups was designed to meet their most pressing needs and to overcome the most limiting deficiencies in

their preparation for employment as dietitians. The program of training or retraining was presented in three units of five days each. It was designed to present continuity of instruction with increasing levels of complexity.

The design also included a statewide short course program for all dietitians in Minnesota with the aim of improving competence and, therefore, increasing total availability of dietetic care.

Pyramidal Structure of Educational Units

Results of the Program

The response of dietitians to the courses was very gratifying. In Year 1, 909 persons participated in 8,820 hours of instruction. This response was far beyond the predicted participation, which was estimated at 155. The courses offered, their locations, and the attendance are compiled in Tables 1 and 2.

Response in Year II was equally satisfying. In the second year, 937 persons participated in 6,030 hours of instruction. The emphasis in the second year was directed toward the statewide one day short courses. This change in emphasis was implemented in response to requests expressed by registrants in Year 1.

Since the 1972 *total* membership of the Minnesota Dietetic Association is 603, it is obvious that many persons attended several education courses. One-day programs were open to all who have responsibility for nutritional support of patients, and a proportionally small number of nurses, social workers, physicians, etc. also benefited.

During the two year program, personnel from more than 200 separate institutions or agencies in Minnesota were registered for the courses.

Evaluation

Evaluation of the five-day courses was designed to test objectively the increase of knowledge for participants. This was accomplished by a program of pre and post testing, and a satisfactory increase in information was demonstrated. For 52 students enrolled in separate five-day courses in diet therapy, the average pre score on a 150 point test was 101.82. The average post test score was 117.54.

For 35 students enrolled in five day courses in normal nutrition, the average pre test score of a 150 point test was 117.29. The average post test score was 140.15.

One-day short courses were evaluated subjectively by participants. This response was overwhelmingly favorable, and comments and requests by registrants were used in the design of courses in Year 2.

On August 17, 1971, following a full year of operation, all Minnesota dietitians were surveyed to obtain information on benefits derived from this program. The number of questionnaires mailed was 685. The numbers returned was 267, a 38.9 percent response.

Pertinent information concerning total project evaluation obtained from this survey is listed in Table 3.

In June of 1972, all members (603) of the Minnesota Dietetic Association were questioned concerning employment status. There were 422 (70%) answers to the questionnaire returned. Of the 422 respondents 314 (74%) are employed, full or part-time, while 86 (20%) are not working. Of the 422 responses, 22 (5%) did not answer this question.

In contrast to the questionnaire of 1968, the percentage of inactive dietitians has decreased from 34% to 20% during a difficult economic period. It is, of course, impossible to measure the effect of this program in relation to the various economic factors operating during this period, but the increase in utilization of already trained manpower is significant.

Summary

In order to facilitate maximum use of dietetic manpower in the State of Minnesota, a two-year program of Continuing Education in Clinical Nutrition was designed. The objective of the proposal was to retrain inactive dietitians, and to offer current information on practice in clinical nutrition to

all persons with responsibility for the nutritional care of patients. The primary goal was to improve patient care by increasing dietetic availability and expertise. Response to the program was far beyond predictions. Maintaining official registration of dietitians was facilitated by the instruction, and non-dietitians were helped to overcome deficiencies of formal preparation in clinical nutrition.

Hopefully, some benefits derive from this program in the direction of controlling costs of patient care by improving performance of one group of allied health professionals through continuing education.

Refresher and Continuing Education in Nursing

A New Role for Minnesota's State Junior Colleges

MARY M. MERGENS, R.N.

The Registered Nurse (R.N.) Refresher and Continuing Education project represents a unique cooperative effort between Northlands Regional Medical Program (NRMP) and Minnesota's State Junior Colleges. Through this association, it is now possible to conduct a four-week R.N. Refresher course or a two to three day continuing education workshop any place in Minnesota where (1) there is a need for such a program and (2) there are enough participants to make a program feasible.

This alliance between NRMP and the Junior College System holds tremendous potential for those concerned with health education and continuing education for health professionals.

The Need for a Coordinated Refresher Program

For years the critical shortage of nurse manpower prompted nationwide efforts to return inactive nurses to the work force. R.N. Refresher courses varying in length and quality have been offered in Minnesota since 1960. Refresher programs have been treated each year as a new problem and have been offered sporadically with little attention to state-wide planning and coordination. Courses were offered by private hospitals until 1965 when the Manpower Development and Training Act of 1962 was amended to include health occupations. Careful planning and coordination in these programs was often difficult however, because of the way funds were released. Often there was insufficient time for instructors to prepare lectures, arrange clinical facilities, order instructional materials and arrange guest lecturers. Recruitment of enrollees was a serious problem, because the MDTA courses required that the nurses be employed before enrolling in the course or that they commit themselves to working for the hospital sponsoring the course. Furthermore, these programs did not take into consideration the degree of insecurity which was so characteristic of students.

In order to correct some of these deficiencies, NRMP funded the original R.N. Refresher Proposal* which initiated a plan to incorporate R.N. Refresher courses into the State Junior College System in order to provide an on-going regional program throughout Minnesota. This program is particularly exciting because, to our knowledge, refresher education is not an on-going program or part of an educational system anywhere else in the United States. Many state nursing associations have inquired about the Minnesota program and have indicated plans to use it as a model in their own states.

The Need for Continuing Education Programs

Although the overall goal of the original R.N. Refresher project was primarily a manpower one —that of upgrading and regionalizing R.N. Refresher training in Minnesota in order to return inactive nurses to the work force—the process of developing and operating the Refresher Project uncovered many unmet and evolving needs among *practicing* nurses in health care facilities throughout the state. In every area where a refresher course was held during the past two years, employed nurses from local hospitals, nursing homes, public health agencies, schools and industries requested permission to attend many of the classes offered as "refresher" education to inactive nurses.

This report is based on a demonstration project entitled "Refresher and Continuing Education in Nursing." It was a component of Northlands Regional Medical Program, Inc. supported by HEW grant #5 GO3 RM-00021. The opinions presented do not constitute endorsement by NRMP, Inc., or by the Department of Health, Education and Welfare.

Mary M. Mergens, R.N., B.S., is Director, R.N. Refresher & Continuing Education, Minnesota State Junior College System.

*The original proposal was jointly prepared and submitted to NRMP by Ruth P. Stryker, then Director of Nursing Education and Publications at Sister Kenny Institute, and the Minnesota State Junior Colleges.

These practicing nurses were finding themselves ill-prepared, insecure and unwilling to accept the new ways in which they were being utilized in the expanding health care systems. Better utilization requires knowledge of new roles and the ability to perform them. During this final year of NRMP funding, the Refresher Project is attempting to adapt its curriculum to meet the educational needs of *practicing,* as well as *non-practicing* nurses.

This shift in emphasis, from refresher to continuing education has encouraged the development of several short-term in-depth programs which are being offered through the Community Service Departments of the Junior Colleges where refresher courses have been offered previously. Communication channels in these areas are fairly well established and local health care institutions have readily accepted and promoted these programs among their employees. Requests have been received from several institutions and individuals who have specified educational needs in the following areas: chemical dependency, pharmacology, geriatrics, nursing care plans, inhalation therapy, rehabilitation nursing, death and the grieving process and teaching and assessment techniques.

These requests reflect the major role which Nursing has come to play in all aspects of health care. As the nation's largest health service profession, Nursing must keep pace with new scientific and technological developments and with the expansion of programs and facilities in order to ensure effective delivery of health care. Nurses are taking on growing responsibilities in family counseling, screening for health problems, setting up community facilities and providing medical services. These expanded roles demand that nurses enter the profession with better preparation and new skills, and that they maintain their knowledge and skill at a level compatible with current practice.

Nursing, like medicine, and the other health care professions, is undergoing unparalleled change. The basic problem lies in finding ways of keeping pace with the increased demands for health care and all the advances in medical and scientific research which foster improved patient care. The growing demand for continuing education programs of all types and the accelerated development of such programs provide supportive evidence that continuing education is acknowledged by both consumers and providers to be one avenue of hope in keeping pace with professional progress. The specific objectives of the R.N. Refresher and Continuing Education project are:

A. To provide an on-going educational vehicle by which inactive nurses can return to their profession, thereby improving the qualitative maldistribution of nursing care in Minnesota.
B. To perfect the Junior College mechanism of offering the refresher courses with maximum effectiveness and efficiency.
C. To adapt certain components of the current refresher curriculum to meeting the needs of employed nurses who are facing expanding demands in their professional roles.
D. To establish within the Junior College System a "clearing house" or resource center of information where individuals or institutions can obtain referrals to the appropriate people, places and programs which will help them to update and increase their knowledge and skills in health care.

Methods

The four-week nurse refresher course combines classroom content based on recall of previous learning and presentation of new information with clinical experience in local hospitals or other health care facilities. It is felt that anything less than 120 hours of instruction does not meet the educational needs of the inactive nurse. The courses are planned with six hour days, five days a week because continuity is lost if classes are stretched over many weeks. Most nurses can plan for an educational program best if it is concentrated for a single month.

Eligibility requirements for the course are very broad so as to provide any interested nurse the

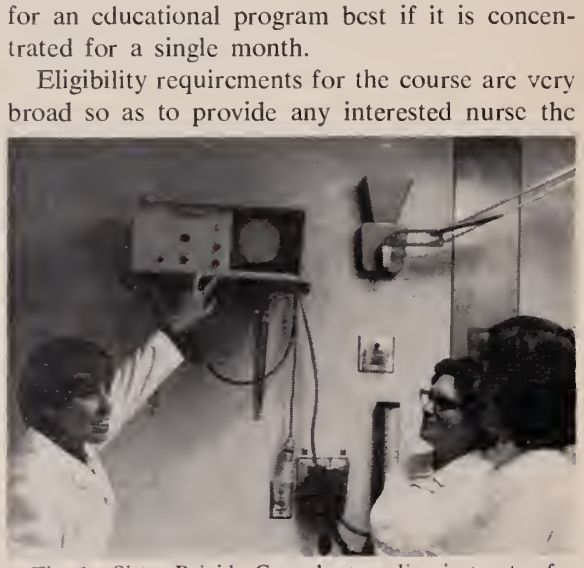

Fig. 1—Sister Brigida Cassady, traveling instructor for the Project demonstrates cardiac monitoring equipment for two nurses enrolled in the refresher course at Metropolitan State Junior College in Minneapolis.

opportunity to update her knowledge. All nurses taking the refresher course must have a current Minnesota license or be in the process of obtaining current licensure.

The course curriculum devotes special attention to the nurse's expanded role in the delivery of health care by including information on teaching and learning, creativity, effective communication, death and grieving, drug abuse, coronary care and much more (See Figures 1 and 2).

The emphasis is on *nursing care* rather than the setting where it is practiced. Another major emphasis is to utilize local health care facilities and resource people in the communities where courses are offered. This principle of participation was designed to make the inactive nurse aware of local health resources and work opportunities.

As sponsoring agent for the project the Junior Colleges provide classroom space, audiovisual equipment, registrar services, and assistance with student recruitment and course publicity. News releases, radio and T.V. spot announcements, college bulletins, descriptive brochures and individual mailings have all proved very effective means of publicity and recruitment.

Instructors for the course must have a minimum of a bachelor's degree and two years of teaching experience. Most have Master's level preparation and are recruited from the area where the course is to be offered. Where library facilities are unavailable and there are no qualified instructors, a traveling library and instructors are provided. Clinical experiences are provided through local health care facilities. Inservice or supervisory personnel assist students with patient care while the instructors prepare assignments and goals for each day's experience.

Per diem stipends are made available to students who must travel outside their own vicinity to attend a course.

It is anticipated that the refresher program will become a permanent component of the Community Service Programs of the Minnesota State Junior Colleges when the three-year affiliation with NRMP expires in March of 1973. This provision to phase out NRMP support and establish an on-going regional program of refresher training in Minnesota was included in the original proposal. Plans are underway at this time to offer the R.N. Refresher Course for college credit (30 hours per week = four credits). These extension credits will make the program eligible for state support and will assist many RN's to earn educational salary increments.

The mechanism for offering the short-term continuing education workshops is much the same as that for the refresher courses. The junior colleges provide assistance with publicity, recruitment and physical arrangements including classroom, registration and fee collections. Workshop faculty are generally guest lecturers who receive honorariums for their services.

Since participation of local community health resources has been such an integral part of the program design, the project has compiled a valuable backlogue of the health resources available in each area where a course has been offered. As the program expands to all the Junior college locations (See Figure 3), the Project will have established working relationships with most of the people and organizations who could help nurses update their knowledge and skills in health care.

This wealth of resource information will be regionally categorized and may eventually provide the foundations of a "clearing house" or resouree center of information. A center such as this which could be readily utilized by individual practitioners, schools of nursing, hospital and nursing home inservice personnel, will require coordination and cooperation of all of Minnesota's "providers" of continuing education.

Evaluation

The evaluation of this program includes both quantitative and qualitative aspects. The quantitative evaluation consists of the number of courses and workshops offered each year, the number of

Fig. 2—Nurses at the Willmar State Junior College course update their knowledge of inhalation therapy procedures through a demonstration and practice session at Community Memorial Hospital in Willmar.

nursing personnel attending each offering, the number of refreshers who return to active employment and the length of time they remain employed. This information is gathered by a follow-up of each refresher at the time of the course and at six month intervals.

The qualitative evaluation will include (1) evaluations of courses by instructors at the end of each offering; (2) evaluation of student performance at the end of each course; (3) evaluation of course by student at the end of the course and 6 months after the course; (4) evaluation of the overall program as it meets state-wide needs for more qualified personnel each year; and (5) evaluation of performance by the employer after three months of employment.

Results

During the first two years of the project, there have been 11 refresher courses with 314 students attending. (See Table 1). Eight of these courses were offered in the Twin Cities area and five in the outlying regions of the state. Approximately 56% of those nurses who responded have returned to active participation in the profession. Although the demand for refresher courses has been greater in the Twin Cities Metropolitan area, regionalization of the program remains a top priority in planning courses.

As a part of the ongoing quantitative evaluation of the project and in order to assess the effectiveness of the refresher courses, questionnaires were sent to the refreshers six months after they completed a course. The results of this initial follow-up survey appear in Table 2. It is interesting to note that although only 56% of those who responded were actually back to work, 65% of those who were not employed indicated their intention to return to the profession within the year. Only 23% of the respondents indicated that they would not return to nursing barring unforeseen circumstances. Most nurses who had not returned to work cited family circumstances as their reason for not returning.

At this time, a second phase of evaluation, that of the re-employed nurse by her employer, is being implemented. This evaluation of performance by the employer reveals the ultimate value of the course. If refreshees are working, the numbers and quality of their work are indeed the most important results of the course.

Discussion

The need to insure the establishment of an educational vehicle by which each new group of nurses can re-enter the work force annually has become increasingly apparent and there is substantial evidence to support the commitment of the Junior College System to this end. Each year the system has increased its financial support of this project's activities and has encouraged other nursing and allied health groups to plan continuing education projects within the junior college system. The R.N. Refresher and Continuing Education Project has with increasing frequency served as a liaison between representatives of a variety of health-related programs (i.e., long term care administration, Project Breakthrough, operating room nurses, community service personnel) and the Junior College Board.

The full potential of the State Junior College System for making continuing education offerings accessible to all health professionals has yet to be realized. As the present trend toward requiring proof of continuing education for relicensure continues to gain impetus among Minnesota's health professionals* the need for an education vehicle will become preponderant. The Junior College system has a well established network of educational facilities throughout Minnesota and has demonstrated enthusiasm and efficiency in implementing continuing education programs for nurses.

The recent report of the HEW Secretary's Committee to Study Extended Roles for Nurses† recommends that:

"Health education centers should undertake curricular innovations that demonstrate the physician-nurse team concept in the delivery of care in a variety of settings under conditions that provide optimum opportunity for both professions to seek the highest levels of competence. Financial support should be made available for programs of continuing nurse education that could prepare

Fig. 3—There are 18 state junior colleges in Minnesota. By 1973 there will be 20—including Riverview at Cambridge and Fairlakes at Fairmount.

the present pool of over one million active and inactive nurses to function in extended roles. The continuing education of nurses should be structured to encourage professional advancement among and through all nursing education programs and by encouraging the use of equivalency examinations to evaluate competence, knowledge and experience."

The potential of the R.N. Refresher and Continuing Education Project to implement this recommendation is enormous. The flexibility inherent in the program and the built-in capacity for frequent revisions, depending on the changing needs of nurses working at the community level, are two essential components of the project. In addition, the program promotes a growing recognition of the importance of physician-nurse collaboration in extending health care services to meet increasing demands. Many Minnesota physicians have participated in the refresher courses and workshops as guest lecturers and in planning clinical learning experiences. The students' written evaluations have reflected their appreciation of the physicians' class presentations, but more importantly, their realization that the medical profession in their own communities is interested and enthusiastic about their decisions to return to nursing.

Summary

A unique cooperative arrangement between

*Minnesota's State Board of Dentistry has already implemented such a proposal and resolutions on similar legislation were debated at the May, 1972 conventions of the Minnesota State Medical Association in Rochester and the American Nurses' Association in Detroit.

†Secretary's Committee to Study Extended Roles for Nurses. "Extending the Scope of Nursing Practice," JAMA, 220:9:1231, 1972.

NRMP and the Junior College System began in May, 1970, when Northlands funded a proposal to increase the number of professional nurses by a regional program of nurse refresher courses. Since that time 319 nurses have completed a refresher course and approximately 60% of these have returned to work. The success of the refresher project and the expressed needs of employed nurses for continuing education programs prompted Northlands and the Junior Colleges to expand their cooperative efforts to include the development of short-term in-depth continuing education workshops. These workshops are designed to help nurses keep pace with new scientific and technological developments and to prepare them for the new roles which are rapidly extending the scope of nursing practice.

As the pressures for a multi-professional approach to patient care have increased, and many Minnesota communities are struggling to coordinate health care facilities and resources with educational institutions, the RN Refresher and Continuing Education Project has cultivated productive and promising relationships with Minnesota's State Junior Colleges—relationships which hold much potential for future contributions to the professional growth of health practitioners.

Training Physicians and Nurses

for Intensive Coronary-Care Units

T. PAUL B. O'DONOVAN, M.B., B.Ch., JUDITH THIERER, R.N., HAROLD T. MANKIN, M.D. AND JOHN P. STOKES, M.D.

THE DEVELOPMENT of the concept of the intensive coronary-care unit (ICCU) is one of the major advances in medical cardiology in recent decades. When the procedure was implemented effectively, a gratifying reduction in in-hospital mortality from acute coronary heart disease was soon attained. In recognition of this, recommendations were made in 1964 at the Second Cardiovascular Conference to promote the ICCU concept nationally. In Minnesota, a special committee was formed to establish priorities for heart-disease control in our state. Members agreed upon five aspects of care in heart disease which should be given special effort, and their recommendations were accepted by the Minnesota Heart Association and the Heart Committee of the Minnesota State Medical Association. The first was implementation of the ICCU concept in our state. The Minnesota Heart Association (MHA) formed an ICCU Subcommittee for this purpose. A survey of coronary deaths in Minnesota for 1966 was undertaken to determine the magnitude of the problem. Major conclusions of this study were that a significant reduction in the hospital mortality rate could be achieved by furthering and advancing the application of the techniques required for the intensive coronary-care unit in hospitals throughout the state. Second, it was noted that there is an urgent need for responsible professional personnel to undergo appropriate orientation and training in the improved techniques of the aggressive management of acute myocardial infarction. Problems revealed by this survey included the following:

1. The number of nurses available was not sufficient for the staffs of future coronary-care units.

2. The current training of nurses did not provide adequate detail relating to coronary heart disease.

3. Medical directors were not generally available for supervision of coronary-care units and there was some reluctance on the part of physicians to assume this responsibility.

An ICCU planning grant was funded by Northlands Regional Medical Program (NRMP). The funds were to be used primarily for the training of physicians in the concepts of acute coronary care. Shortly after this planning grant was funded, NRMP requested the ICCU Committee to submit a full five-year operational grant to provide training programs in coronary care to meet the training needs of medical and allied health personnel. The primary objective of this operational project was to decrease further the death rate from coronary heart disease in Minnesota by means of multidisciplinary improvement in patient care. This was to be accomplished through the training of physicians, nurses, hospital administrators and medical electronic technicians in the modern concepts of coronary care.

The thrust of the project has been primarily educational and several approaches have been used.

Consultation Service

An on-site consultation service for the region was established with a corps of trained physicians and nurses, hospital administrators and medical electronic technicians as resource people. This service was designed to advise and assist hospital staffs and others interested in establishing coronary-care units and in problem-solving in existing units. Services included: planning and design of a coronary-care unit, proper choice of monitoring and other electronic equipment, advice regarding

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

This demonstration project was sponsored by the Minnesota Heart Association, Minneapolis, Minnesota. It was a component of Northlands Regional Medical Program, Inc. supported by HEW grant #5 GO3 RM-00021. Judith Thierer is Director, Minnesota Heart Association-Northlands Regional Medical Program ICCU Course, Rochester Methodist Hospital, Rochester, Minnesota.

electrical safety procedures, development of guidelines and operating policies related to the electronic equipment and its maintenance. Approximately 128 of these on-site consultations have been provided throughout the state (Figure 1).

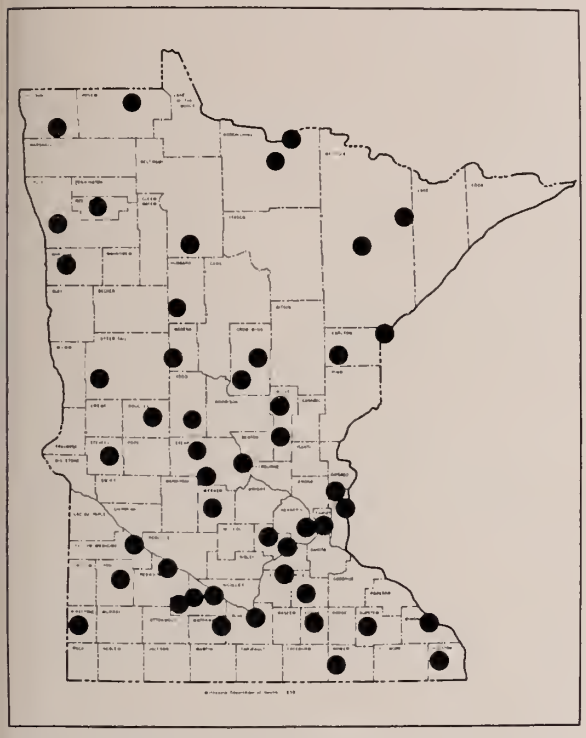

Fig. 1—Sites of on-site consultations, April 1, 1969, to March 31, 1972.

CORE Conference

A series of CORE conferences were held. These consisted of two-to-three-day intensive reviews of specific topics in acute coronary care, and were provided by the ICCU Committee with the assistance of an outside guest faculty. Table 1 lists these conferences, their location and the topics. The attendance at these conferences was generally limited to physicians actually directing or actively working in coronary-care units and their head nurses or their representatives. Two hundred eighty-five physicians and 78 nurses attended the eight conferences. Because the topics varied from conference to conference, many of the physicians and nurses were "repeaters," and attended several of these conferences.

The format of these conferences varied depending on the topic and the faculty. The most effective format which evolved was as follows: didactic presentations were made on specific topics and these were then followed by round-table discussions with one group leader and five or six of the participants. These periods were devoted to actual problem-solving with the use of information provided in the didactic presentations. When appropriate, actual demonstrations were given; for example, in the area of electrical hazards in coronary-care units. At some conferences, supervised experience in such technical skills as the insertion of a temporary transvenous cardiac pacemaker and the proper use of defibrillators and cardioverters was provided for the participants. It was felt that active participation by the physicians and nurses attending these conferences was the major ingredient in the success of this facet of the education activities.

Nursing Training and Refresher Courses

The advent of the coronary-care unit has provided a unique opportunity for the true multidisciplinary approach to the seriously ill patient. Increasing responsibility has been placed upon the nurse to the point at which she now has to make decisions and to initiate therapy in situations formerly reserved for the physician. Recognition of this fact is most important, for it can truly be said that the sine qua non of a successful, effective coronary-care unit is its corps of expert CCU nurses. Accordingly, a major objective of our project was to provide training in coronary care for those nurses already working in coronary-care units and for those who planned to work in units that were under construction or planned in the future. This was primarily accomplished through a formal ICCU nurses' course based at the Rochester Methodist Hospital in Rochester, Minnesota.

This facility comprises a full-size, fully equipped, two-bed mock ICCU, classroom facilities, office and storage space. It was completed

in November, 1969, and the first formal course began on Nov. 17, 1969. This program is an intensive four-week course designed to prepare the nurse for her role as a highly skilled member of the coronary-care team.

The curriculum was organized to impart an advanced background in acute cardiovascular nursing. Areas of special emphasis include comprehensive coverage of the anatomy and physiology of the cardiovascular, respiratory, and renal systems; the epidemiology of coronary arterial disease and myocardial infarction; the pathophysiology of coronary arterial disease; fluid, electrolyte and acid-base balance; the medical and nursing management of the acute myocardial infarction and its complications; the nutritional needs of the cardiac patients; psychologic aspects of coronary-care nursing; electrocardiography with special emphasis on dysrhythmias; cardiac pacemakers; defibrillation and cardioversion; the pharmacology of cardiovascular drugs; external cardiopulmonary resuscitation; principles of pulmonary ventilation and support; the team concept of coronary-care nursing; the medicolegal aspects of coronary-care nursing; and coronary-care unit management.

Enrollment is limted to 12 nurses per course. Didactic presentations are augmented with audiovisual aids, small group-study sessions, experience in the simulated unit and clinical experience in the coronary-care units of Rochester Methodist Hospital and St. Marys Hospital. The director of the ICCU nursing course and her assistant are responsible for much of the instruction; members of the Departments of Cardiovascular Disease, Pathology and Electronic Engineering of the Mayo Clinic also serve as instructors. Opportunities for individual instructor-student conferences are provided. A most useful teaching tool has been replaying of videotape recordings of the students' performances. For example, a simulated resuscitation and defibrillation for cardiac arrest may be videotaped. Replay of the videotape and constructive criticism by the instructors and other members of the group have been invaluable in effectively teaching correct procedures and techniques.

To date 20 such courses have been held at the Rochester Methodist Hospital (RMH), with a total attendance of 232 nurses. Five similar courses were held under the auspices of the joint MHA-NRMP ICCU project at St. Joseph's Hospital in St. Paul. Figure 2 shows the geographic distribution of the attending nurses.

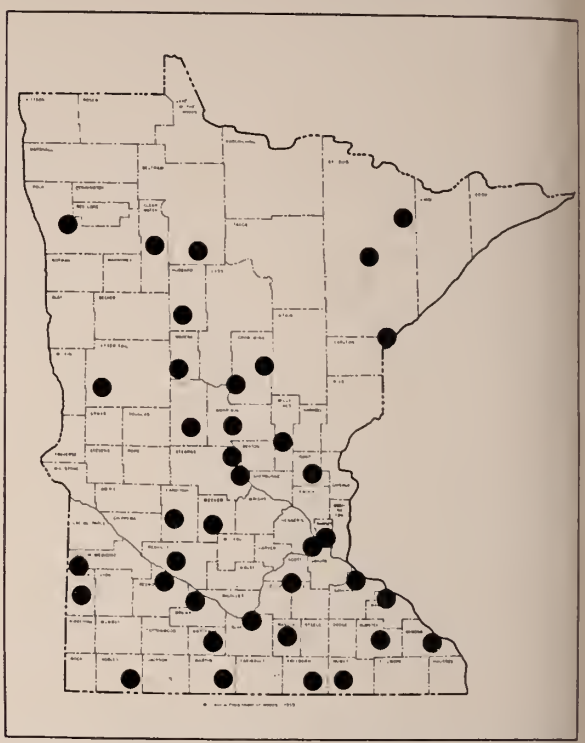

Fig. 2—Location of nurses attending the ICCU nursing course, April 1, 1969, to March 31, 1972.

For evaluation purposes, pre-tests and post-tests are given to each group attending the course at RMH. The mean pre-test score for the first 17 courses was 72.1% and the mean post-test score for the same period was 93.2%. A two-day refresher course is offered yearly to update knowledge and skills of graduates of this course. The four refresher courses have been attended by 187 nurses and have been highlighted by the presence of guest faculties from outside the area, as well as by leaders in coronary-care nursing in the state of Minnesota. For evaluation purposes, the pre-test and post-test were given again to the group attending the 1971 refresher course, and mean scores for this group were as follows: pre-test, 72.9%; post-test, 94%; and 87.1% on the refresher. Of the 54 participants in the retest at the refresher course, 45 showed an average loss of retention of seven percentage points, three had the same score and six increased an average of a little more than two percentage points. A small number of this group recently repeated the same test at the end of two years, and retention figures from this group will be available shortly.

Area Seminars

Fifteen area seminars within our region were held. These were designed as half-day to one-day courses, the subject matter being decided in consultation with the hospitals or physicians requesting the seminar. Eleven of these seminars were for physicians, nurses and hospital administrators and four were specifically for medical electronic technicians (MET). The location of these seminars is shown in Figure 3. The early seminars were aimed primarily at generating an interest in and concern for development of coronary-care units where none existed. Later, the seminars were devoted to recent advances in coronary care for the attending physicans and nurses. Table 2 lists the number and types of our educational programs and the attendance.

TABLE 2

Dial Access Program

Eighteen fve- to six-minute pre-recorded presentations dealing with topics in the field of acute coronary care were prepared under the supervision of the ICCU committee. These were made available through the Dial Access Program of NRMP.

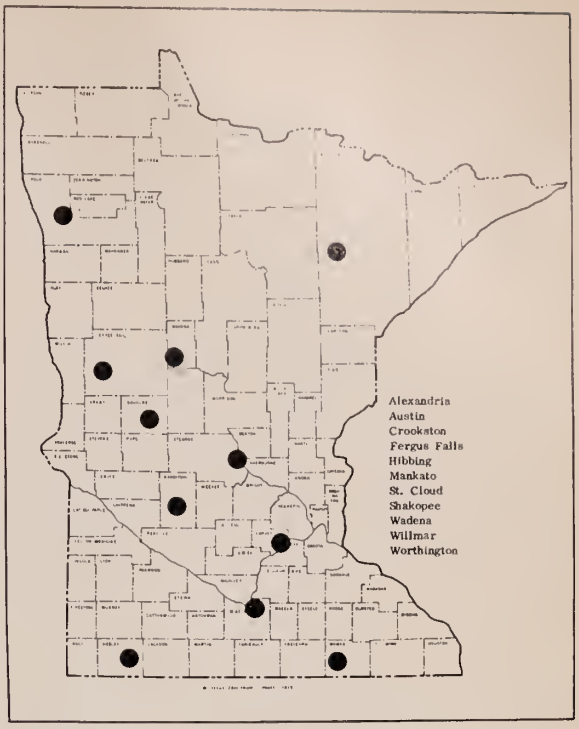

Fig. 3—Sites of area seminars, April 1, 1969, to March 31, 1972.

Coronary-Care Newsletter

A regular coronary-care newsletter was established under the editorship of Dr. John Morgan. It was mailed to professional personnel involved in coronary care throughout the state. This newsletter contained information on the joint MHA-NRMP ICCU project, as well as summaries and comments on recent articles in the cardiologic literature dealing with acute coronary care.

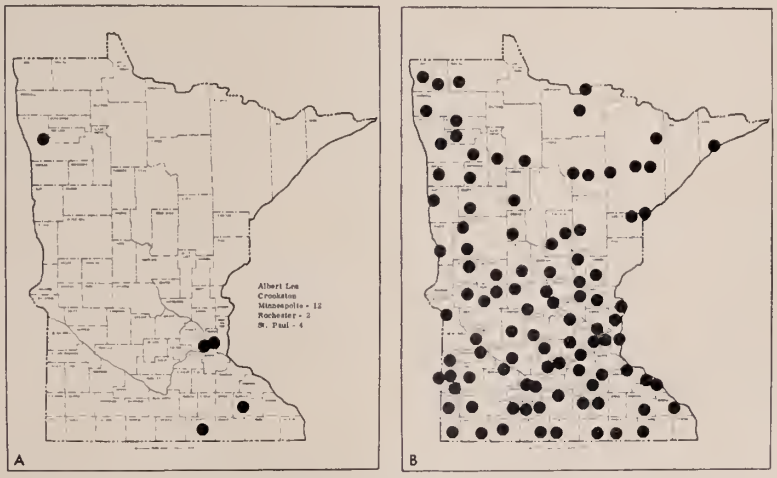

Fig. 4—*(A)* Number of ICCU's and MICU's (Medical Intensive Care Unit) in 1967. *(B)* ICCU's and MICU's in 1972.

Educational Materials

Educational materials were provided either permanently or on loan through the project. The average number of these mailed out annually has averaged 500. In addition to pamphlets and booklets, specific films were made available on loan, and mannequins for the teaching of cardiopulmonary resuscitation also were provided on loan.

Results

The results to date have been gratifying. Figure 4 shows that in 1967 there were 18 Minnesota hospitals with ICCU's, combined medical ICU-CCU's (MICU) or with portable monitoring equipment. By Mar. 31, 1972, 119 Minnesota hospitals had such facilities. Prior to the development of the ICCU concept, the average in-hospital mortality rate from acute myocardial infarction ranged between 30 and 35%. The Minnesota coronary-care mortality study of the ICCU project, now in its second year, has shown that the over-all mortality rate from acute myocardial infarction in Minnesota is now 22%. It is well known that most acute coronary deaths occur within the first few hours after the onset of an episode of ischemia. Thus, we have been gratified to find that the average time from onset of symptoms to arrival at the coronary-care unit has decreased from four and a half to three and a half hours in our most recent survey.

A one-year follow-up study showed that 77.8% of the nurse participants in the ICCU training course were working in coronary care at the time they attended the program. Many participants worked in medical or surgical intensive-care units, emergency rooms, cardiac postoperative surgical units and postanesthetic rooms, and they returned to these same areas after completion of the course. However, of the 77.8% actually working in coronary-care units, 91.4% were still engaged in coronary care at the end of one year. Equally impressive is the fact that 91.2% were still employed by their sponsoring agency at the end of one year. This figure is somewhat misleading in view of the fact that some hospitals do ask their nurses to stay for one year after taking the course.

Members of the ICCU project are pleased to note the improvement in the care of the patient with acute coronary disease in Minnesota. The aid of the Minnesota Heart Association and the Heart Committee of the Minnesota State Medical Association, for their sponsorship, and of Northlands Regional Medical Program, for its support and funding, has been crucial. We should like to express our appreciation to the dedicated present and past members of the ICCU project who have given so much of their time and effort to further this cause. We also owe much to the physicians, nurses, hospital administrators and electronic technicians of Minnesota who attended these educational programs and in turn improved coronary care in their area. Their unselfish support and cooperation have been largely responsible for the success of the project. The training of health professionals in acute coronary care in Minnesota has been truly a multidisciplinary team effort.

Continuing Education for Laboratory Personnel

in Small Rural Hospitals

BARBARA MERRITT, M.S., M.T. (ASCP)

RAPIDLY CHANGING technology in the health sciences has intensified the need for continuing education of all health care professionals. If competent on-the-job performance is to be maintained, personnel must be kept informed of new developments and continuing education programs must be relevant to work needs.

Availability of continuing education programs for laboratory personnel and other health professionals has increased in recent years.[1,2] While content of these programs was related to improving skills and imparting new knowledge, they were seldom evaluated in terms of actual improvement in the performance of participants.

Accurate and precise laboratory results are required by physicians for good medical care. Surveys show that laboratories in small rural hospitals are more likely to produce inaccurate results.[3-7] The personnel in such hospitals are also less likely to have access to educational programs which can aid in upgrading their skills.[4]

In June, 1970 the Minnesota Society of Medical Technologists initiated a project in continuing education which was designed to upgrade laboratory performance in 125 small rural hospitals. The project, Continuing Education for Laboratory Personnel (CELP Project), was conducted over a period of 21 months. In order to bring continuing education close to the work location, two familiar types of programs were offered: (1) regional workshops and (2) consultation visits. Content of both programs was geared to the basic skills and functions of personnel in small hospital laboratories.

The project design was developed to provide an objective means of evaluating the effectiveness of the programs on improving laboratory performance. Workshops and consultation were offered alone and in combination so that the relative effect of each type of program and the possible reinforcement effect of combining them could be studied.

This demonstration project was sponsored by the Minnesota Society of Medical Technologists. It was a component of Northlands Regional Medical Program, Inc. supported by HEW grant #5 GO3 RM-00021. The opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

Methods

During the initial planning phase, the 125 individual hospitals were divided into three groups —workshop, consultation, and combined workshop and consultation. Personnel from hospitals in the workshop group were invited to regional workshops. Personnel from hospitals in the consultation group were scheduled to receive individual consultation visits. The personnel in the combined group hospitals received invitations to the workshops plus individual consultation visits.

The 1970 Directory of Licensed Hospitals and Related Institutions was used to identify small rural hospitals and their locations. Small hospitals were defined as those with a capacity of less than 100 beds.[5,8] Rural hospitals were defined as those lying outside the metropolitan areas of Minneapolis-St. Paul and Duluth. The state was divided into eight regions having fairly uniform distribution of small rural hospitals (see Figure).

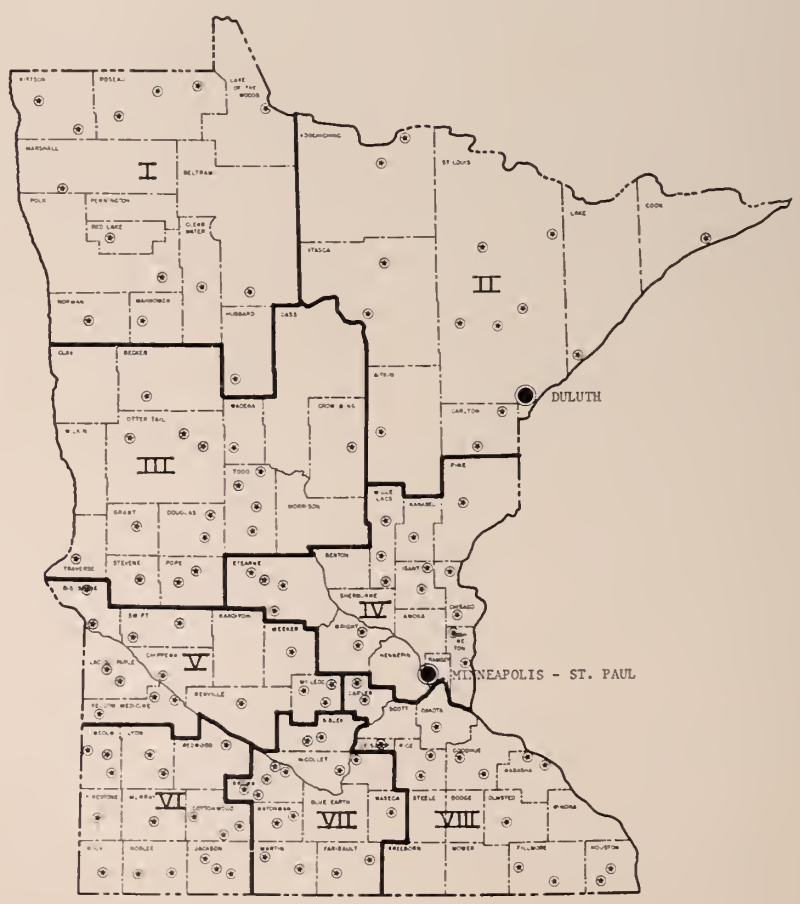
Educational background of the laboratory personnel was identified by means of a Minnesota Department of Health questionnaire. Personnel were placed in two categories according to their educational background: "specialist/technologist" and "lab technician/aid." The "specialist/technologist" is equivalent to a registered medical technologist with four years of educational background and certified MT(ASCP) by the American Society of Clinical Pathologists. The "lab technician/aid" includes ASCP Certified Laboratory Assistants (CLA), Minnesota certified Medical Laboratory Assistants (MLA), proprietary school graduates, military trained technicians, and on-the-job

trained technicians. All personnel in this category were considered to have educational backgrounds equivalent to one year of formal training.

Hospitals were then classified according to the educational background of their laboratory personnel into two classes:

Class I—those employing at least one four-year person ("specialist/technologist")

Class II—those employing only one-year people ("lab technician/aids")



Once classified, hospitals were randomly assigned by class within each region, to one of the three educational program groups. Table 1 shows the distribution of hospitals in each group among the eight regions.

Two letters were sent to each hospital administrator announcing the project and requesting his cooperation, first by the Project Director and second by the executive director of the Minnesota Hospital Association. Although initial response was good, followup communication was necessary to achieve maximum participation.

Workshop Programs

Area vocational technical schools with MLA programs, junior colleges, state colleges, and branches of the University of Minnesota were selected as workshop sites in the eight regions. Site visits were conducted to determine adequacy of equipment and facilities and to gain the cooperation of school administrators. Scheduling of regional workshops began in October, 1970 and continued through December, 1971.

Two series of workshop programs were developed and presented. The format included lecture demonstrations and slide presentations as well as laboratory exercises. Program content covered the four major laboratory subjects—blood banking, clinical chemistry, hematology, and microbiology. The information on educational background of personnel showed that there were 2.7 times as many one-year technicians employed in the hospitals as four-year technologists. A mixed audience with regard to background and experi-

Class II—hospitals employing only one-year people.

ence was anticipated, and content was therefore geared to a basic level. Open discussion was encouraged to provide a forum for more advanced questions and specific problems.

Both series of two-day workshops consisted of half-day or full-day sessions in each of the four subjects. The workshops were scheduled on a Friday and Saturday in each region to facilitate attendance for those individuals who could not leave work easily.

Consultation Program

Consultation was carried out by staff technologists in the same four subject areas emphasized in the workshops. Visits were scheduled with consent of the hospital administrator and laboratory personnel. Consultation was also conducted by telephone and request visits were scheduled as needed. Scheduling of visits began in October, 1970 and continued through March, 1972.

Equipment and routine procedures were inventoried during the first visit. Correspondence and reports of each visit were kept to maintain up-to-date information on recommendations and changes in procedures which were adopted. The laboratory's most recent report from the Clinical Chemistry Study[9] was used to determine consultation needs for specific chemical procedures. As consultation progressed, a collection of new procedures and revisions in technique were developed. These procedures and techniques were then offered to laboratory personnel during subsequent visits for information and implementation.

Methods of Evaluation

Separate questionnaires were developed by the workshop faculty for each workshop. Participants were asked to complete a questionnaire for each session stating his feelings regarding relevance of the topics to working situations, level of subject content, pacing of the presentation, and future topics of interest. An information form was also used to poll preference of days for future workshops.

Responses to questions on pacing obtained after the first workshop in each series were used by the faculty to judge and correct the speed of presentation in subsequent presentations. A poll of the requests for future topics was used to determine subject matter for the second series of workshops.

The effectiveness of consultation was based on the personal observations of the staff technologists during and following the visits. These observations were recorded in the consultation reports for future reference.

The objective evaluation consisted of measuring the effectiveness of the two educational programs, offered alone and in combination, on improvement of laboratory performance in chemistry. Performance was evaluated by using the results generated by those laboratories participating in the Clinical Chemistry Study, a voluntary proficiency program of the Minnesota Department of Health.[9] This evaluation is currently being carried out by comparing laboratory performance before the project started and after the programs were completed. The details of the design and results will be published elsewhere.

Results

Minnesota has a large number of small hospitals —134 of the 184 licensed general hospitals, or 73%, have capacities of less than 100 beds. Nine of these are located in metropolitan areas where resident pathology services and ASCP registered medical technologists are readily available. The remaining 125 are distributed fairly uniformly across the state with less density in the upper third where lakes and forest lands predominate (see Figure).

The response of hospital administrators and laboratory personnel to our invitation to participate in the educational programs was especially gratifying. Of the 125 hospitals, 123 agreed to participate (99%). One hospital closed shortly after the programs started, and one hospital refused to participate.

Participation in Workshops

Actual participation of the laboratory personnel in the workshops is shown for both the workshop and combined groups in Table 2. The workshop group maintained a level of 60% participation during both series of workshops. Although all but one hospital had agreed to participate, 11 never actually sent personnel to any workshops. The other 29 hospitals were represented at one or both of the series, and 24 hospitals were represented at each series. The reasons for nonparticipation seemed to be personal; there was no difference in size or geographic location between those hospitals represented and those not represented.

The combined group showed slightly less participation than the workshop group (45-55% compared with 60%). Fifteen of the hospitals in this group never sent personnel to any workshops. Again there was no difference in size or geographic location between hospitals represented and those not represented. All of these hospitals received consultation visits as part of the combined group program. Perhaps some of them felt that the personal consultation method was adequate for their needs.

Although participation was less in the combined group, the difference was small. This demonstrated the popularity of the workshop programs. The total participation figures for the 82 hospitals invited to the workshops was 57% for the first series and 52% for the second. Eliminating the 11 hospitals in the workshop group which were never represented, and therefore did not participate in any aspect of the project, there was an overall level of 90% participation in the project among the 124 hospitals.

Participation in Consultation

Two or three visits were made to each laboratory receiving consultations during the 18 month period—a total of 203 visits. Because the staff technologists traveled to them for consultation services, the personnel in the consultation and combined groups were a captive audience and participation was therefore 100%. Effective consultation during the initial visits was delayed until personal rapport could be developed between the personnel in the laboratory and the consulting medical technologist. Laboratory personnel were encouraged to telephone collect if they had problems between visits. This service was not used extensively, but the frequency of calls increased during the latter months of the project. Towards the end of the project laboratory personnel began to take full advantage of all consultation services.

Evaluation and Comparison of the Two Educational Methods

The opinions expressed by participants on the workshop evaluation questionnaires showed that the content level was appropriate (Table 3). Re-

sponses to content of Red and White Blood Cell Morphology workshops show lower percentages than the others. This is due to the fact that participants were given the opportunity to give one or both of two answers—"satisfactory" or "what you anticipated."

On the whole, the faculty felt that the workshops were very successful in terms of satisfying needs of the learners in the subject areas presented. Feedback from individuals during discussion periods and requests for duplicate sets of some of the materials used, indicated that many of the participants intended to share the information with others in their laboratories who were unable to attend.

Consultation was more difficult to evaluate because of the individualized approach used. Personal rapport increased as the consulting staff technologists made repeated visits. Rapport with some of the personnel in the combined group was reinforced by attendance at the workshops. This relationship increased opportunities to suggest changes and recommend new or different procedures. In a few instances, the laboratories were so well staffed and current in their procedures that the consultation visits were little more than social calls. In most cases, however, a great deal of new or additional information was supplied, and laboratory personnel were very interested in expanding their background knowledge and applying the new knowledge to their working situation.

The reinforcement obtained by combining the two educational methods seemed to have the greatest effect on upgrading laboratory performance. Workshops provided a classroom group approach to presenting general information, while consultation afforded personnel in individual hospital laboratories the opportunity to obtain specific information for their needs. Whether the combined methods actually produced the most improvement in performance will be determined by the statistical evaluation currently being conducted.

Other studies have shown that participation in proficiency or evaluation programs has resulted in improved performance.[7] Of the 123 hospitals participating in the project, 87 had been participating in the Clinical Chemistry Study for one to three years. Improvement in performance resulting from participating in that proficiency program should have taken place before this project began. Therefore, if additional improvement in performance is documented, it can be directly attributed to the educational programs offered.

Discussion

Since the regional workshops were conducted on an invitational basis, participation was voluntary. Two factors had a considerable effect on attendance—weather and vacations. Blizzard conditions during the first series of workshops caused rescheduling twice in one region, and the travelling faculty was trapped both times. Attendance also dropped off during the summer vacation months. Small hospitals have greater difficulty than larger hospitals in providing coverage during vacation periods. Spring and fall proved to be the best times of the year to conduct regional workshops in Minnesota.

Although the workshop participation was less than we had hoped for, the overall level was greater than that experienced in an earlier study in Minnesota dealing with evaluation of blood bank training programs.[6] In that study continuous training courses were required of personnel in 39 hospitals, and central and regional training courses were made available to the remaining 115 hospitals participating in the study. Only 36% of the

115 hospitals were represented at the central and regional training courses. Since the students attending the courses varied widely in basic education and experience, instructors found it difficult to set the level of instruction to meet all student needs. Students with brief basic education were reluctant to ask questions when they didn't understand, and reluctance increased when more fully trained students were present.

We experienced similar reluctance to ask questions among some of the participants at our workshops. However, concerted efforts of the faculty to keep the content basic, to elicit response during the discussion periods, and to maintain a casual, friendly approach resulted in adequate to lively response from most of the participants. Individuals who were reluctant to speak out in the group frequently asked questions on a personal basis during coffee breaks and lunch.

The need for and benefit derived from continuing education programs for laboratory personnel in small hospitals has been noted by Sattler in her report of a similar RMP sponsored program in Washington and Alaska.[10] That program differed from ours in that travel expenses were provided to bring people into centrally located laboratory training centers for refresher and on-the-job training, rather than to carry the programs out to the area of employment. The training sessions were not formal sessions, but were individualized instruction sessions applicable to the person's own laboratory situation. After three years of operation, 74% of their 156 trainees had come from hospitals of 100 beds or less.[11]

Although cost figures are not readily available, the CELP Project and the Washington/Alaska continuing education program are expensive programs to carry out. It is not known at the present time which of these approaches is most efficient economically or most effective in actually upgrading performance. The question of determination of economic efficiency would require development of new techniques for cost accounting analysis. Continuing education programs have rarely been evaluated in the past in terms of actually producing improvement in performance. Hopefully, the objective evaluation studies of both of these programs will answer the question of effectiveness in improving performance.

Summary

During the past two years, the Minnesota Society of Medical Technologists has conducted a program in continuing education for laboratory personnel in small rural hospitals. Program activities included regional workshops and consultation visits to individual hospital laboratories. Four laboratory subject areas were covered—blood banking, clinical chemistry, hematology, and microbiology.

The 125 small rural hospitals were divided into three groups—consultation, workshop, and combined consultation and workshop. Out of the 123 which agreed to participate, 112 hospitals participated in one or more of the educational programs offered.

Over an 18 month period, 56 regional workshop programs were presented and 203 consultation visits were made. Once personal rapport was established, the consultation visits became quite effective. Participation in the workshops exceeded 50%, and response from participants was highly favorable for content and application.

Although objective data on improvement in performance has not yet been analyzed, the technique of combining regional workshops and personal consultation visits seemed to be better than providing either program alone.

Librium® and (chlordiazepoxide HCl) concomitant use

Librium (chlordiazepoxide HCl) is used as adjunctive antianxiety therapy concomitantly with certain specific medications of other classes of drugs, such as cardiac glycosides, antihypertensive agents, diuretics, anticholinergics and antacids.

Antianxiety effectiveness: Demonstrated in a broad range of psychologic and physical dysfunctions; indicated when reassurance and counseling are not enough and until, in the physician's judgment, anxiety has been reduced to tolerab appropriate levels.

Effect on mental acuity: Usually minimal on proper maintenance dosage.

Safety: An excellent clinical record. In gene use, the most common side effects reported hav been drowsiness, ataxia and confusion, particularly in the elderly and debilitated.

in relief of clinically significant anxiety

Librium®
(chlordiazepoxide HCl)

5-mg, 10-mg, 25-mg capsules up to 100 mg daily in severe anxiety

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are rever ble in most instances by proper dosage adjustment, but are also occasiona ly o served at the lower dosage ranges. In a few instances syncope has been report Also encountered are isolated instance skin eruptions, edema, minor menstru irregularities, nausea and constipation, extrapyramidal symptoms, increased a decreased libido—all infrequent and generally controlled with dosage reduc tion; changes in EEG patterns (low-vo'ta fast activity) may appear during and af treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasio ally, making periodic blood counts and liver function tests advisable during pro tracted therapy.
Supplied: Librium® capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.
